EnergyPlus™ Documentation, v8.4.0	31
Input Output Reference	31
The Encyclopedic Reference to EnergyPlus Input and Output	31
1 Input-Output Reference	33
1.1 What's different about EnergyPlus Input and Output?	33
1.1.1 EnergyPlus Input Processing	33
1.1.2 General Input Rules	33
1.1.3 EnergyPlus Output Processing	34
1.2 IDD Conventions	34
1.2.1 IDD – IP Units	37
1.3 Input – Output Descriptions (Document)	39
1.3.1 Input Descriptions	39
1.3.2 Output Descriptions	40
1.4 Group -- Simulation Parameters	41
1.4.1 Version	41
1.4.2 Timestep	41
1.4.3 ConvergenceLimits	42
1.4.4 Building	43
1.4.5 SurfaceConvectionAlgorithm:Inside	46
1.4.6 SurfaceConvectionAlgorithm:Outside	47
1.4.7 HeatBalanceAlgorithm	47
1.4.8 HeatBalanceSettings:ConductionFiniteDifference	48
1.4.9 ZoneAirHeatBalanceAlgorithm	49
1.4.10 ZoneAirContaminantBalance	49
1.4.11 Carbon Dioxide Outputs	50
1.4.12 Generic Contaminant Outputs	50
1.4.13 ShadowCalculation	50
1.4.14 Output:Diagnostics	51
1.4.15 Output:DebuggingData	52
1.4.16 Output:PreprocessorMessage	52
1.4.17 ZoneCapacitanceMultiplier:ResearchSpecial	52
1.4.18 SimulationControl	53
1.4.19 ProgramControl	54
1.4.20 Meter:Custom	54
1.4.21 Meter:CustomDecrement	55
1.4.22 Custom Meter Examples	56
1.4.23 Simulation Parameter Outputs	56
1.5 Group – Compliance Objects	56
1.5.1 Compliance:Building	57
1.6 Group -- Location – Climate – Weather File Access	57

1.6.1 Site:Location	57
1.6.2 SizingPeriod:DesignDay	57
1.6.3 Sizing Period Design Day Outputs	62
1.6.4 Longer Design Periods	63
1.6.5 SizingPeriod:WeatherFileDays	63
1.6.6 SizingPeriod:WeatherFileConditionType	64
1.6.7 RunPeriod	65
1.6.8 RunPeriod:CustomRange	67
1.6.9 RunPeriodControl:SpecialDays	68
1.6.10 RunPeriodControl:DaylightSavingTime	69
1.6.11 WeatherProperty:SkyTemperature	69
1.6.12 Site:WeatherStation	70
1.6.13 Site:HeightVariation	71
1.6.14 Site:GroundTemperature:BuildingSurface	72
1.6.15 Site:GroundTemperature:Shallow	72
1.6.16 Site:GroundTemperature:Deep	72
1.6.17 Site:GroundTemperature:Undisturbed:FiniteDifference	73
1.6.18 Site:GroundTemperature:Undisturbed:KusduaAchenbach	73
1.6.19 Site:GroundTemperature:Undisturbed:Xing	74
1.6.20 Site:GroundDomain:Slab	75
1.6.21 Site:GroundDomain Outputs	78
1.6.22 Site:GroundDomain:Basement	78
1.6.23 Site:GroundTemperature:FCfactorMethod	81
1.6.24 Site:GroundReflectance	81
1.6.25 Site:GroundReflectance:SnowModifier	82
1.6.26 Site:WaterMainsTemperature	82
1.6.27 Site:Precipitation	83
1.6.28 RoofIrrigation	84
1.6.29 Solar and Visible Spectrum Objects	84
1.6.30 Site:SolarAndVisibleSpectrum	84
1.6.31 Site:SpectrumData	85
1.6.32 Climate Group Outputs	85
1.6.33 Weather Data Related Outputs	85
1.6.34 Outputs for local temperature/wind speed calculations	89
<b>1.7 Group -- Schedules</b>	<b>90</b>
1.7.1 Day Type	90
1.7.2 ScheduleTypeLimits	91
1.7.3 Day Schedules	92
1.7.4 Schedule:Day:Hourly	92
1.7.5 Schedule:Day:Interval	92
1.7.6 Schedule:Day:List	93
1.7.7 Week Schedule(s)	93
1.7.8 Schedule:Week:Daily	93
1.7.9 Schedule:Week:Compact	94
1.7.10 Schedule:Year	94
1.7.11 Schedule:Compact	95
1.7.12 Schedule:Constant	96

1.7.13 Schedule:File	97
1.7.14 Schedule Outputs	98
<b>1.8 Group – Surface Construction Elements</b>	<b>99</b>
1.8.1 Specifying the Building Envelope	99
1.8.2 Material and Material Properties	99
1.8.3 Material	99
1.8.4 Material:NoMass	101
1.8.5 Material:InfraredTransparent	101
1.8.6 Material:AirGap	102
1.8.7 MaterialProperty:MoisturePenetrationDepth:Settings	103
1.8.8 Moisture Penetration Depth (EMPD) Outputs	104
1.8.9 MaterialProperty:PhaseChange	104
1.8.10 MaterialProperty:VariableThermalConductivity	106
1.8.11 Conduction Finite Difference (CondFD) Outputs	106
1.8.12 MaterialProperty:HeatAndMoistureTransfer:Settings	107
1.8.13 MaterialProperty:HeatAndMoistureTransfer:SorptionIsotherm	107
1.8.14 MaterialProperty:HeatAndMoistureTransfer:Suction	108
1.8.15 MaterialProperty:HeatAndMoistureTransfer:Redistribution	109
1.8.16 MaterialProperty:HeatAndMoistureTransfer:Diffusion	109
1.8.17 MaterialProperty:HeatAndMoistureTransfer:ThermalConductivity	110
1.8.18 Heat and Moisture (HAMT) Outputs	110
1.8.19 Materials for Glass Windows and Doors	112
1.8.20 WindowMaterial:Glazing	112
1.8.21 WindowMaterial:Glazing:RefractionExtinctionMethod	115
1.8.22 Glass Optical Properties Conversion	116
1.8.23 WindowMaterial:GlazingGroup:Thermochromic	116
1.8.24 WindowMaterial:GlazingGroup:Thermochromic Outputs	120
1.8.25 WindowMaterial:Gas	120
1.8.26 WindowMaterial:GasMixture	122
1.8.27 WindowMaterial:Gap	122
1.8.28 WindowGap:DeflectionState	123
1.8.29 WindowGap:SupportPillar	123
1.8.30 WindowMaterial:SimpleGlazingSystem	124
1.8.31 WindowMaterial:Shade	125
1.8.32 WindowMaterial:Blind	127
1.8.33 WindowMaterial:ComplexShade	131
1.8.34 WindowMaterial:Screen	136
1.8.35 WindowMaterial:Shade:EquivalentLayer	139
1.8.36 WindowMaterial:Drape:EquivalentLayer	140
1.8.37 WindowMaterial:Blind:EquivalentLayer	142
1.8.38 WindowMaterial:Screen:EquivalentLayer	145
1.8.39 WindowMaterial:Glazing:EquivalentLayer	146
1.8.40 WindowMaterial:Gap:EquivalentLayer	149
1.8.41 Material:RoofVegetation	150
1.8.42 Ecoroof / RoofVegetation outputs	153
1.8.43 MaterialProperty:GlazingSpectralData	154
1.8.44 Construction	155

1.8.45 Site:GroundTemperature:FCfactorMethod	158
1.8.46 Constructions - Modeling Underground Walls and Ground Floors Defined with C and F Factors for Building Energy Code Compliance	158
1.8.47 Construction:CfactorUndergroundWall	158
1.8.48 Construction:FfactorGroundFloor	159
1.8.49 Construction:InternalSource	160
1.8.50 Composite Wall Constructions	162
1.8.51 Construction:ComplexFenestrationState	162
1.8.52 WindowThermalModel:Params	164
1.8.53 Matix:TwoDimension	165
1.8.54 Construction:WindowEquivalentLayer	166
1.8.55 Construction:WindowDataFile	166
1.8.56 Construction Element Outputs	167
<b>1.9 Group – Thermal Zone Description/Geometry</b>	<b>167</b>
1.9.1 Zone	167
1.9.2 Zone Outputs	169
1.9.3 Zone Thermal Output(s)	169
1.9.4 ZoneList	172
1.9.5 ZoneList Outputs	173
1.9.6 ZoneGroup	173
1.9.7 ZoneGroup Outputs	173
1.9.8 Surface(s)	174
1.9.9 Interzone Surfaces	175
1.9.10 Surface View Factors	175
1.9.11 GlobalGeometryRules	175
1.9.12 Surfaces	176
1.9.13 Walls	177
1.9.14 Wall:Exterior	177
1.9.15 Wall:Adiabatic	177
1.9.16 Wall:Underground	178
1.9.17 Wall:Interzone	179
1.9.18 Roofs/Ceilings	180
1.9.19 Roof	180
1.9.20 Ceiling:Adiabatic	181
1.9.21 Ceiling:Interzone	181
1.9.22 Floors	182
1.9.23 Floor:GroundContact	182
1.9.24 Floor:Adiabatic	183
1.9.25 Floor:Interzone	184
1.9.26 Windows/Doors	185
1.9.27 Window	185
1.9.28 Door	186
1.9.29 GlazedDoor	187
1.9.30 Window:Interzone	188
1.9.31 Door:Interzone	189
1.9.32 GlazedDoor:Interzone	190
1.9.33 Surface Vertices	192

1.9.34 Building Surfaces - Detailed	193

## EnergyPlus™ Documentation, v8.4.0

---

### Input Output Reference

#### The Encyclopedic Reference to EnergyPlus Input and Output

*(the ins and outs of EnergyPlus)*

COPYRIGHT (c) 1996-2015 THE BOARD OF TRUSTEES OF THE UNIVERSITY OF ILLINOIS AND THE REGENTS OF THE UNIVERSITY OF CALIFORNIA THROUGH THE ERNEST ORLANDO LAWRENCE BERKELEY NATIONAL LABORATORY. ALL RIGHTS RESERVED. NO PART OF THIS MATERIAL MAY BE REPRODUCED OR TRANSMITTED IN ANY FORM OR BY ANY MEANS WITHOUT THE PRIOR WRITTEN PERMISSION OF THE UNIVERSITY OF ILLINOIS OR THE ERNEST ORLANDO LAWRENCE BERKELEY NATIONAL LABORATORY. ENERGYPLUS IS A TRADEMARK OF THE US DEPARTMENT OF ENERGY.

# 1 Input-Output Reference

This document is intended to be an encyclopedic reference for the EnergyPlus Input Data Dictionary (IDD), Input Data File (IDF) and potential resultant outputs (various output files).

The following descriptions are “grouped” by the elements in the IDD (ref: Getting Started Document and the IDD Conventions). In some cases, the descriptions of reporting will be done for an object (e.g. Lighting electrical consumption or thermal comfort value for a group of people) and in some cases for the entire group (e.g., ambient condition reports).

## 1.1 What’s different about EnergyPlus Input and Output?

The usual procedure for non-interactive programs is to process all the input necessary to “do the job”, perform the actions required by the input, and somewhere along the way produce reports on the actions. Usually, there will be error messages on incorrect input statements and/or incorrect conditions detected during processing. Usually, the input is echoed in its entirety so that the context of errors is shown clearly.

Results are typically output into reports as well as a compilation of various inputs reformatted into different groupings than were originally entered (defaults filled in, etc.)

EnergyPlus does all the above. However, some nuances are different from the usual actions.

### 1.1.1 EnergyPlus Input Processing

1) EnergyPlus reads the data dictionary (Energy+.idd) and the input data file (in.idf) prior to doing anything else. Only after this is done does processing start. HOWEVER, the input processor only knows as much as the data dictionary has told it. It knows which fields should be alpha and which should be numeric. All of this information (including the IDD) is echoed to the audit file (audit.out) in case errors occur. Most of the errors show up (out of context) in the standard error file (eplusout.err) – there might be enough information to decipher where the error is or you may have to look at the more inclusive audit file. Invalid numeric fields are detected during this processing and default numeric fields are filled. For more information on the IDD, its structure and implications, please see the IDD Conventions discussion below.

2) The biggest difference between EnergyPlus and more traditional input processing is that EnergyPlus is modular in its actual filling in the details for the simulation. Because of the modular structure of EnergyPlus, each module is responsible for “getting” its own input. It receives this input from the input processor in the form of alpha and numeric fields. Each module typically gets all its input the first time it is called. The implication for the user is that error messages may show up in somewhat peculiar places. A further implication is that no order is needed in the input data file! Data that is not needed by a particular simulation is not processed.

3) The data dictionary has the capability to do “automatic” range checking on numeric fields as well as fill in numeric defaults. Both filling in defaults and “automatic” range checking are done when the data is read. Other checks may need a combination of fields and won’t be done until the data is “processed” (after the simulation starts).

4) A couple of other differences that might not be true in other programs: Blanks are significant in alpha fields **SO** DesignDay is not the same as Design Day (1 space between Design and Day) nor Design Day (2 spaces between Design and Day). Alpha objects, however, *are* case insensitive SO DesignDay is the same as ‘designday’ or ‘SizingPeriod:DesignDay’.

### 1.1.2 General Input Rules

Rules shown here are for the input data files. Rules about the Input Data Dictionary are shown in the Interface Developer’s Guide (there is much similarity and overlap) but most users don’t need to touch the IDD (Input Data Dictionary).

The input data file is the primary file that EnergyPlus uses to create the building simulation. The only additional files are referenced by certain objects (such as the Schedule:File object). The input is order-independent; data can appear in any order and will be retrieved and sorted as necessary by the EnergyPlus simulation modules. In addition, EnergyPlus allocates everything dynamically, so there are no limitations as to number of zones, surfaces, etc.

- The initial line of an input object **MUST** have a comma or semicolon.
- Fields do not extend over line boundaries. Usually, if a comma or (as appropriate) semi-colon is not the last field value on a line, one will be inserted. Of course, several fields may appear on a single line as long as they are comma separated. (And the last could be followed by a semi-colon).
- Commas delimit fields – therefore, no fields can have embedded commas. No error will occur but you won’t get what you want. You cannot surround a field with “ to accommodate commas in the fields.
- Blank lines are allowed.
- The comment character is an exclamation “!”. Anything on a line after the exclamation is ignored.
- Input records (aka input line length) can be up to 500 characters in length. If you go over that, no error will occur but you won’t get what you want.
- Each Alpha string in the input data file (aka alpha field length) can be up to 100 characters in length. Anything beyond that is truncated. This would apply to all names (such as zone name, node name, schedule name) in fields.

- Each Alpha string (including Section and Class/Object keywords) is mapped to UPPER case during processing, unless the *retaincase* flag marks the field in the IDD. Get routines from the EnergyPlus code that use the Section and Object keywords automatically map to UPPER case for finding the item. The primary drawback with this is that error messages coming out of the input processor will be in UPPER case and may not appear exactly as input.
- Special characters, such as tabs, should NOT be included in the file. However, tabs can be accommodated and are turned into spaces.
- All numbers can be flexibly input and are processed into single precision variables (i.e. 1.0, 1.000, 1, .1E+1 are all processed equally).

### 1.1.3 EnergyPlus Output Processing

- 1) Unlike the usual formatted output text formatted reports, EnergyPlus usual output is either at the summary or at the detailed (variable) level. Summary reports exist for many inputs as well as sizing results. The more detailed variable level reporting is produced as “stream of consciousness” (as the simulation happens) and must be post-processed for more sensible viewing. Note that the terms “output variable” and “output variable” (accessed by the Output:Variable and/or Output:Meter objects) are used interchangeably in this document.
- 2) Most EnergyPlus reporting can be readily viewed in current spreadsheet programs – or other software that can process “delimited variable” reports. In these kind of reports, each “column” is separated from the next by a “delimiter”. Typical delimiters are “comma” and “tab”. Gradually, EnergyPlus reporting is moving from all comma separated reports to allow the user to select the delimiter via “style” objects.
- 3) Styled reports allow for more selectable output reporting but also increase the number of output files as we have chosen to create the report names with extensions that typify the actual reporting. Depending on the reporting, these can be:
  - ✓ Tab – reports with a .tab extension have tabs as the delimiter. These report files (directly from EnergyPlus) will be named something like “eplus<xxx>.tab” where the <xxx> is a short name of the kind of report (e.g. Zsz for Zone Sizing, Map for Daylighting Map)
  - ✓ Csv – reports with a .csv extension have commas as the delimiter. These are also specially formatted for use in spreadsheets (such as the compilation of results from the eplusout.eso file into the eplusout.csv file using the default post-processor program).
  - ✓ Txt – reports with a .txt extension have spaces as the “delimiter” but only certain of these are really formatted the way you might expect: where multiple spaces make printing with a non-proportional font would produce readable output.
  - ✓ Html – reports with a .html extension are “web-browser” ready.

## 1.2 IDD Conventions

The following is a basic description of the structure of the IDD (it’s actually taken directly from the IDD file). As noted within! signifies a comment character as does the \. \ has also been adopted as a convention for including more specific comments about each field in an object. These have been used with success in the IDFEditor and it is hoped the flexibility will provide other interface developers with useful information.

```
!IDD_Version **VERSION NUMBER**
! *****
! This file is the Input Data Dictionary (IDD) for EnergyPlus.
! The IDD defines the syntax and data model for each type of input "Object."
! Lines in EnergyPlus input files (and IDD) are limited to 500 characters.
!
! Object Description
! -----
! To define an object (a record with data), develop a key word that is unique
! Each data item to the object can be A (Alphanumeric string) or N (numeric)
! Number each A and N. This will show how the data items will be put into the
! arrays that are passed to the Input Processor "Get" (GetObjectItem) routines.
! All alpha fields are limited to 100 characters. Numeric fields should be
! valid numerics (can include such as 1.0E+05) and are placed into double
! precision variables.
!
! NOTE: Even though a field may be optional, a comma representing that field
! must be included (unless it is the last field in the object). Since the
! entire input is "field-oriented" and not "keyword-oriented", the EnergyPlus
! Input Processor must have some representation (even if blank) for each
! field.
!
! Object Documentation
! -----
! In addition, the following special comments appear one per line and
! most are followed by a value. Comments may apply to a field or the object
! or a group of objects.
!
! Field-level comments:
!
! \field          Name of field
!                  (should be succinct and readable, blanks are encouraged)
!
! \note          Note describing the field and its valid values. If multiple lines,
! start each line with \note. Limit line length to 100 characters.
```

```

!
! \required-field To flag fields which may not be left blank
!                 (this comment has no "value")
!
! \begin-extensible Marks the first field at which the object accepts an extensible
!                 field set. A fixed number of fields from this marker define the
!                 extensible field set, see the object code \extensible for
!                 more information.
!
! \units           Units (must be from EnergyPlus standard units list)
!                 EnergyPlus units are standard SI units
!
! \ip-units        IP-Units (for use by input processors with IP units)
!                 This is only used if the default conversion is not
!                 appropriate.
!
! \unitsBasedOnField For fields that may have multiple possible units, indicates
!                 the field in the object that can be used to determine
!                 the units. The field reference is in the A2 form.
!
! \minimum         Minimum that includes the following value
!
! \minimum>        Minimum that must be > than the following value
!
! \maximum         Maximum that includes the following value
!
! \maximum<        Maximum that must be < than the following value
!
! \default         Default for the field (if N/A then omit entire line)
!
! \deprecated     This field is not really used and will be deleted from the object.
!                 The required information is gotten internally or
!                 not needed by the program.
!
! \autosizable    Flag to indicate that this field can be used with the Auto
!                 Sizing routines to produce calculated results for the
!                 field. If a value follows this, then that will be used
!                 when the "Autosize" feature is flagged. To trigger
!                 autosizing for a field, enter Autosize as the field's
!                 value. Only applicable to numeric fields.
!
! \autocalculatable Flag to indicate that this field can be automatically
!                 calculated. To trigger auto calculation for a field, enter
!                 Autocalculate as the field's value. Only applicable to
!                 numeric fields.
!
! \type           Type of data for the field -
!                 integer
!                 real
!                 alpha      (arbitrary string),
!                 choice     (alpha with specific list of choices, see
!                             \key)
!                 object-list (link to a list of objects defined elsewhere,
!                             see \object-list and \reference)
!                 external-list (uses a special list from an external source,
!                             see \external-list)
!                 node       (name used in connecting HVAC components)
!
! \retaincase     Retains the alphabetic case for alpha type fields
!
! \key            Possible value for "\type choice" (blanks are significant)
!                 use multiple \key lines to indicate all valid choices
!
! \object-list    Name of a list of user-provided object names that are valid
!                 entries for this field (used with "\reference")
!                 see Zone and BuildingSurface:Detailed objects below for
!                 examples.
!                 ** Note that a field may have multiple \object-list commands.
!
! \external-list  The values for this field should be selected from a special
!                 list generated outside of the IDD file. The choices for the
!                 special lists are:
!                 autoRDDvariable
!                 autoRDDmeter
!                 autoRDDvariableMeter
!                 When one of these are selected the options for the field
!                 are taken from the RDD or MDD file or both.
!
! \reference      Name of a list of names to which this object belongs
!                 used with "\type object-list" and with "\object-list"

```

```

!           see Zone and BuildingSurface:Detailed objects below for
!           examples:
!
!           Zone,
!             A1 , \field Name
!                 \type alpha
!                 \reference ZoneNames
!
!           BuildingSurface:Detailed,
!             A4 , \field Zone Name
!                 \note Zone the surface is a part of
!                 \type object-list
!                 \object-list ZoneNames
!
!           For each zone, the field "Name" may be referenced
!           by other objects, such as BuildingSurface:Detailed, so it is
!           commented with "\reference ZoneNames"
!           Fields that reference a zone name, such as BuildingSurface:Detailed's
!           "Zone Name", are commented as
!           "\type object-list" and "\object-list ZoneNames"
!           ** Note that a field may have multiple \reference commands.
!           ** This is useful if the object belongs to a small specific
!           object-list as well as a larger more general object-list.
!
! Object-level comments:
!
! \memo           Memo describing the object. If multiple lines, start each line
!                 with \memo.
!                 Limit line length to 100 characters.
!
! \unique-object  To flag objects which should appear only once in an idf
!                 (this comment has no "value")
!
! \required-object To flag objects which are required in every idf
!                 (this comment has no "value")
!
! \min-fields     Minimum number of fields that should be included in the
!                 object. If appropriate, the Input Processor will fill
!                 any missing fields with defaults (for numeric fields).
!                 It will also supply that number of fields to the "get"
!                 routines using blanks for alpha fields (note -- blanks
!                 may not be allowable for some alpha fields).
!
! \obsolete       This object has been replaced though is kept (and is read)
!                 in the current version. Please refer to documentation as
!                 to the dispersal of the object. If this object is
!                 encountered in an IDF, the InputProcessor will post an
!                 appropriate message to the error file.
!                 usage: \obsolete New=>[New object name]
!
! \extensible:<#\> This object is dynamically extensible -- meaning, if you
!                 change the IDD appropriately (if the object has a simple list
!                 structure -- just add items to the list arguments (i.e. BRANCH
!                 LIST). These will be automatically redimensioned and used during
!                 the simulation. <#\> should be entered by the developer to signify
!                 how many of the last fields are needed to be extended (and EnergyPlus
!                 will attempt to auto-extend the object). The first field of the first
!                 instance of the extensible field set is marked with \begin-extensible.
!
! \begin-extensible See previous item, marks beginning of extensible fields in
!                 an object.
!
! \format         The object should have a special format when saved in
!                 the IDF Editor with the special format option enabled.
!                 The options include SingleLine, Vertices, CompactSchedule,
!                 FluidProperties, ViewFactors, and Spectral.
!                 The SingleLine option puts all the fields for the object
!                 on a single line. The Vertices option is used in objects
!                 that use X, Y and Z fields to format those three fields
!                 on a single line.
!                 The CompactSchedule formats that specific object.
!                 The FluidProperty option formats long lists of fluid
!                 properties to ten values per line.
!                 The ViewFactor option formats three fields related to
!                 view factors per line.
!                 The Spectral option formats the four fields related to
!                 window glass spectral data per line.
!
! \reference-class-name Adds the name of the class to the reference list
!                 similar to \reference.

```

```

!
! Group-level comments:
!
! \group          Name for a group of related objects
!
!
! Notes on comments
! -----
!
! 1. If a particular comment is not applicable (such as units, or default)
! then simply omit the comment rather than indicating N/A.
!
! 2. Memos and notes should be brief (recommend 5 lines or less per block).
! More extensive explanations are expected to be in the user documentation

```

## 1.2.1 IDD – IP Units

In addition, the IDD contains indications of IP (inch-pound) units for the EnergyPlus standard SI (Systems International) units. These may be used by input and output interfaces to display values in the IP system. As noted, if the IP units are “standard” (first block below), then no `ip-units` is expected in the field. Note that for some fields – due to their multiple use (for example, schedule values) – there cannot be a ip-unit designation.

```

! Default IP conversions (no \ip-units necessary)

## 1.3 Input – Output Descriptions (Document)

### 1.3.1 Input Descriptions

In the descriptions below, the fields for each input object will be described but the Energy+.idd descriptions will not be shown. Refer to the actual Energy+.idd file for complete specifications. Energy+.idd is a text file that can be viewed with many text editors or word processors. The Site:Location object will serve as an example.

```

```

The IDD excerpt above is the complete definition as seen in the IDD file.

First, the object name is given. (Site:Location) This is followed by a comma in both the definition (IDD) and in an input file (IDF). In fact, all fields except the terminating field of an IDD class object and IDF object are followed by commas. The final field in an IDD class object or in an IDF object is terminated by a semi-colon.

Next is an alpha field, the location name. As noted above, for input, spaces are significant in this field. The main inputs for Site:Location are numeric fields. These are numbered (as is the alpha field) for convenience. The \ designations will show various information about the objects as described above in the IDD conventions discussion. Of importance for reading this document are the units and possible minimum and maximum values for a field.

There is automatic processing of the \minimum, \maximum and \default data for numeric fields. Any infractions of the \minimum, \maximum fields are automatically detected and messages will appear in the standard error file. After all the input is checked, infractions will cause program termination (before the bulk of the simulation is completed). Defaults are also enforced if you leave the numeric field blank.

Some objects need all the parameters listed by the definition; some do not. In the descriptions that follow, we will try to indicate which parts are optional. Usually, these will be the last fields in the object input or definition. Even if items are not used for a particular object (e.g. Multiplier in the FenestrationSurface:Detailed and type=Door), the field must be included unless it is the *last field in the object*. So, for this instance, one must include a multiplier field (must be numeric and would need to obey any \minimum, \maximum rules) for doors.

Two spreadsheet files are included with the installation:

- ExampleFiles.xls – shows many details about the included example files including highlights of features.
- ExampleFiles-ObjectsLink.xls – shows, for each object, the first three occurrences of that object in an example file.

### 1.3.2 Output Descriptions

In the descriptions below, we will endeavor to have each object’s output displayed as well as each of the outputs described. The output variables for a run are selected by choosing the Output:VariableDictionary object. This object displays the available output variables for a run on the **eplusout.rdd** (regular variables) and **eplusout.mdd** (meter variables) files. Two significant styles are available for these displays and the descriptions below may have one for some objects and another for other objects. The variables are the same but will look a bit different. For clarity, the two displays are shown below:

Note that the IDF-Editor can interpret both sets of files and assist you in getting output variables into your input files. But you will have to successfully run your input file first.

The Simple (or regular) display looks like the following figure and is interpreted:

**Zone/HVAC** – when the output is produced at the “Zone” timestep (ref: number of timesteps in each hour) or at the “HVAC” aka System timestep (which can vary for each hour).

**Average/Sum** – whether this is a averaged value over the reporting period (such as a temperature or rate) or whether this is a summed value over the reporting period. Reporting periods are specified in the Output:Variable or Output:Meter objects.

<**Variable Name**> -- The variable name one uses for reporting is displayed (e.g., Site Outdoor Drybulb Temperature) along with the units (e.g., [C]).

Example from the **eplusout.rdd** file:

- Zone,Average,Site Outdoor Air Drybulb Temperature [C]
- Zone,Average,Site Outdoor Air Dewpoint Temperature [C]
- Zone,Average,Site Outdoor Air Wetbulb Temperature [C]
- Zone,Average,Site Outdoor Air Humidity Ratio [kgWater/kgAir]
- Zone,Average,Site Outdoor Air Relative Humidity [%]
- Zone,Average,Site Outdoor Air Barometric Pressure [Pa]
- Zone,Average,Wind Speed [m/s]
- Zone,Average,Site Wind Direction [deg]
- Zone,Average,Site Sky Temperature [C]
- HVAC,Sum,Zone Air System Sensible Heating Energy [J]
- HVAC,Sum,Zone Air System Sensible Cooling Energy [J]
- HVAC,Average,Zone Air System Sensible Heating Rate [W]
- HVAC,Average,Zone Air System Sensible Cooling Rate [W]
- HVAC,Average,Zone Air Temperature [C]
- HVAC,Average,Zone Thermostat Air Temperature [C]

Note that the **eplusout.mdd** file is similar, but meters are only available at the Zone timestep.

- Zone,Meter,Electricity:Facility [J]
- Zone,Meter,ExteriorLights:Electricity [J]
- Zone,Meter,Grounds Lights:ExteriorLights:Electricity [J]
- Zone,Meter,EnergyTransfer:Facility [J]
- Zone,Meter,EnergyTransfer:Building [J]
- Zone,Meter,EnergyTransfer:Zone:R13WALL WALLS [J]

The IDF display has all the same information in an IDF-ready form (i.e., you could copy and paste it into your input file using a text editor).

Example from the **eplusout.rdd** file:

- Output:Variable,\*,Site Outdoor Air Drybulb Temperature,hourly; !- Zone Average [C]
- Output:Variable,\*,Site Outdoor Air Dewpoint Temperature,hourly; !- Zone Average [C]
- Output:Variable,\*,Site Outdoor Air Wetbulb Temperature,hourly; !- Zone Average [C]
- Output:Variable,\*,Site Outdoor Air Humidity Ratio,hourly; !- Zone Average [kgWater/kgAir]
- Output:Variable,\*,Site Outdoor Air Relative Humidity,hourly; !- Zone Average [%]
- Output:Variable,\*,Site Outdoor Air Barometric Pressure,hourly; !- Zone Average [Pa]
- Output:Variable,\*,Zone Air System Sensible Heating Energy,hourly; !- HVAC Sum [J]
- Output:Variable,\*,Zone Air System Sensible Cooling Energy,hourly; !- HVAC Sum [J]
- Output:Variable,\*,Zone Air System Sensible Heating Rate,hourly; !- HVAC Average [W]
- Output:Variable,\*,Zone Air System Sensible Cooling Rate,hourly; !- HVAC Average [W]
- Output:Variable,\*,Zone Air Temperature,hourly; !- HVAC Average [C]
- Output:Variable,\*,Zone Thermostat Air Temperature,hourly; !- HVAC Average [C]

All of the same information appears in a slightly different form and defaults to “hourly” reporting frequency (which, of course, can be changed when you put it into your input file). The “\*” is preselected so that you would be reporting for all those items.

## 1.4 Group -- Simulation Parameters

This group of objects influences the simulation in various ways.

### 1.4.1 Version

#### 1.4.1.1 Field: Version Identifier

The Version object allows you to enter the proper version that your IDF was created for. This is checked against the current version of EnergyPlus and a Severe error issued (non-terminating) if it does not match the current version string. Note that versions are often significant and there is no guarantee that the older file will run in the newer versions of the program. See IDF Version Updater (Auxiliary Programs Document) for methods of changing the older files to newer versions.

### 1.4.2 Timestep

#### 1.4.2.1 Field: Number of Timesteps per Hour

The Timestep object specifies the “basic” timestep for the simulation. The value entered here is usually known as the Zone Timestep. This is used in the Zone Heat Balance Model calculation as the driving timestep for heat transfer and load calculations. The value entered here is the number of timesteps to use within an hour. Longer length timesteps have lower values for Number of Timesteps per Hour. For example a value of 6 entered here directs the program to use a zone timestep of 10 minutes and a value of 60 means a 1 minute timestep. The user’s choice for Number of Timesteps per Hour must be evenly divisible into 60; the allowable choices are 1, 2, 3, 4, 5, 6, 10, 12, 15, 20, 30, and 60.

The choice made for this field has important implications for modeling accuracy and the overall time it takes to run a simulation. Here are some considerations when choosing a value:

- The solution technique used in EnergyPlus has been designed to be stable with zone timesteps of up to sixty minutes (Number Timesteps in Hour = 1). However, 60 minutes is considered a “long” timestep and it should only be used in rare occasions where there is no HVAC system, accuracy is not a concern, and short run times are critical. Such long timesteps are not recommended to use because simulation results are more accurate for shorter timesteps, of say 10 minutes or less (Number of Timesteps per Hour of 6 or more). Shorter zone timesteps improve the numerical solution of the Zone Heat Balance Model because they improve how models for surface temperature and zone air temperature are coupled together. Longer timesteps introduce more lag and lead to more a dampened dynamic response.
- Simulation run time increases with shorter timesteps or larger values for Number of Timesteps per Hour. The effect varies with the nature of the model. The user can test out different values on their particular model to understand the implications for his or her particular case. Sometimes large models with multizone HVAC and Plant systems execute nearly as fast with 15 minute timesteps as with 60 minute timesteps because fewer iterations are required in the system modeling since the prior timestep’s results are close to the final outcome of next timestep.
- The weather data files usually have 60-minute (or hourly) data. However, it does not follow that this should be used as the basis for choosing the zone timestep because:
- EnergyPlus carefully interpolates the weather data between data points for use at shorter timesteps. This is discussed in a later section: Weather Data Hourly Interpolation

- Many aspects of a model have time scales that differ from the that of the weather data. A goal of the modeling is to predict how the building will respond to the weather. However, the building's response is not *governed* by the time scale that the weather data are available at, but rather the time scales of the dynamic performance of the thermal envelope as well as things like schedules for internal gains, thermostats, and equipment availability.
- If the model will include calculating the cost of electricity, then the user should be aware that many electric utility tariffs base charges on demand windows of a specified length of time. If the choice of Number of Timesteps per Hour is not consistent with the demand window, then unexpected results may be obtained. For reasonable prediction of the maximum rates for electricity use for in calculating demand charges, the length of the zone timestep needs to be consistent with the tariff's demand window. The following table lists what values are consistent with various demand windows.

Demand Window	Applicable Number of Timesteps per Hour
QuarterHour	4, 12, 20, or 60
HalfHour	2, 4, 6, 10, 12, 20, 30, or 60
FullHour, Day, Week Any	

There is also second type of timestep inside EnergyPlus that is known as the System Timestep. This is a variable-length timestep that governs the driving timestep for HVAC and Plant system modeling. The user cannot directly control the system timestep (except by use of the ConvergenceLimits object). When the HVAC portion of the simulation begins its solution for the current zone timestep, it uses the zone timestep as its maximum length but then can reduce the timestep, as necessary, to improve the solution. The technical details of the approach are explained in the Engineering Documentation under "Integrated Solution Manager".

Users can see the system timestep used if they select the "detailed" frequency option on an HVAC output variable (e.g. Zone Air Temperature). To contrast, the "Zone" variables will only be reported on the zone timestep (e.g. Zone Mean Air Temperature).

And, the IDF example:

```
Timestep, 6; !Suggested default for most system simulations
```

Suggested defaults are 4 for non-HVAC simulations, 6 for simulations with HVAC, 20 is the minimum for ConductionFiniteDifference and HeatAndMoistureFiniteElement simulations. Green roof (ref: Material:RoofVegetation) also may require more timesteps.

Note that hourly data (such as outdoor conditions expressed by Design Days or Weather data) are interpolated to the Zone Timestep. This is discussed in a later section: Weather Data Hourly Interpolation

### 1.4.3 ConvergenceLimits

This item is an "advanced" feature that should be used only with caution. It is specifically included to assist some users "speed up" calculations while not overly compromising accuracy. The user must judge for him/herself whether the reduced run time is useful.

#### 1.4.3.1 Field: Minimum System Timestep

Usually the minimum system timestep is allowed to vary from the zone timestep (as maximum) to a minimum timestep of 1 minute during certain system calculations. This might be when the system turns on or off, for example. Entering 0 in this field sets the minimum system timestep to be the same as the zone timestep. Otherwise the units of the field are minutes. It's probably a good idea to have any minimum entered be a divisor of the zone timestep.

#### 1.4.3.2 Field: Maximum HVAC Iterations

The HVAC Manager will iterate to a solution or up to a set number of iterations. If not "converged", then a warning error appears:

```
SimHVAC: Maximum iterations (20) exceeded for all HVAC loops, at CHICAGO IL USA TMY2-94846 WMO#=725300, 10/07 14:06 - 14:08
```

In order to reduce time used in simulating your building, you may choose to enter a lesser number than the default of 20 for the maximum number of iterations to be used. Or, you may wish to enter a bigger number for certain buildings. To get more information printed with a "max iteration" message, you need to enter a "Output:Diagnosics, DisplayExtraWarnings;" command (which may also generate other warnings than just this one).

#### 1.4.3.3 Field: Minimum Plant Iterations

The plant system modeling includes a solver that iterates within a single HVAC manager iteration. This input field and the next one provide some control over how the plant solver iterates. This field sets a minimum threshold for plant iterations. The default for this field is the value "2" which indicates that a minimum of two full plant model iterations will be performed every time plant is called by the HVAC manager. For faster performance with simple plant systems, this input field could be set to the value "1". For complicated plant systems that present difficulties to solve, this value may need to be set higher to ensure accuracy but at the expense of speed. Complicated plant systems include those with several interconnected loops, sizing miss-matches such that plant components are starved of flow compared to their desired flow, heat recovery systems, and thermal load following onsite generators.

#### 1.4.3.4 Field: Maximum Plant Iterations

The plant system solver iterates within a single HVAC manager iteration. This input field and the previous one provide some control over how the plant model iterates. This field sets a maximum limit for plant iterations. The default for this field is the value "8" which indicates that the plant solver will exit after having

completed eight full iterations. This value can be raised for better accuracy with complex plants or lowered for faster speed with simple plants. The output variable called "Plant Solver Sub Iteration Count" (typically reported at the "detailed" frequency) is useful for understanding how many plant solver iterations are actually being used during a particular simulation. The lower limit of the value for this field is "2."

Use in an IDF:

```
ConvergenceLimits,
  0,          !- Minimum System Timestep (0=same as zone timestep)
  25,        !- Maximum HVAC Iterations
  3,          !- Minimum Plant Iterations
  9;         !- Maximum Plant Iterations
```

### 1.4.4 Building

The Building object describes parameters that are used during the simulation of the building. There are necessary correlations between the entries for this object and some entries in the Site:WeatherStation and Site:HeightVariation objects, specifically the Terrain field.

#### 1.4.4.1 Field: Building Name

Building name is specified for output convenience.

#### 1.4.4.2 Field: North Axis

The Building North Axis is specified **relative to true North**. Buildings frequently do not line up with true north. For convenience, one may enter surfaces in a "regular" coordinate system and then shift them via the use of the North Axis. The value is specified in degrees from "true north" (clockwise is positive).

The figure below shows how the building north axis can be rotated to correspond with one of the major axes of an actual building. The relevance of this field is described more completely under "GlobalGeometryRules"; in particular, the value of "North Axis" is *ignored* if a coordinate system other than "relative" is used.

Figure 1. Illustration of Building North Axis

#### 1.4.4.3 Field: Terrain

The site's terrain affects how the wind hits the building – as does the building height. In addition, the external conduction method usually has its own parameters for the calculation. Please see the Engineering Documentation, External Conduction section for particulars. The legal values for this field are shown in the following table.

Table 1. Values for "Terrain"

Terrain Type Value	Terrain Description
Country	Flat, Open Country
Suburbs	Rough, Wooded Country, Suburbs
City	Towns, city outskirts, center of large cities
Ocean	Ocean, Bayou flat country
Urban	Urban, Industrial, Forest

#### 1.4.4.4 Warmup Convergence

The following two fields along with the minimum and maximum number of warmup days (also in this object) define the user specified criteria for when EnergyPlus will "converge" at each environment (each sizing period or run period set as Yes in the SimulationControl object). EnergyPlus "runs" the first day of the

environment (starting with a set of hard-coded initial conditions) until the loads/temperature convergence tolerance values are satisfied (next two fields) or until it reaches "maximum number of warmup days". Note that setting the convergence tolerance values too loose will cause the program to be satisfied too early and you may not get the results you expect from the actual simulation.

#### 1.4.4.5 Field: Loads Convergence Tolerance Value

This value represents the number at which the loads values must agree before "convergence" is reached. Loads tolerance value is a fraction of the load.

#### 1.4.4.6 Field: Temperature Convergence Tolerance Value

This value represents the number at which the zone temperatures must agree (from previous iteration) before "convergence" is reached. (Units for this field is delta C).

Convergence of the simultaneous heat balance/HVAC solution is reached when either the loads or temperature criterion is satisfied.

All tolerances have units so the temperature tolerance is in degrees C (or degrees K) and the loads tolerance is in Watts. Both tolerances work the same way, just one looks at temperatures and one looks at heating and cooling loads. After the second warm-up day, the program compares the maximum temperature experienced in a space with the maximum temperature from the previous day. If those two temperatures are within the tolerance, then it has passed the first warm-up check.

It does a similar comparison with lowest temperatures experience within all the zones. If the current simulation day and the previous day values are within the tolerance, then it has passed the second warm-up check. Similar things are done with the loads tolerance and the maximum heating and cooling loads that are experienced within the spaces. Those are compared individually to the values for the previous day. If they are both in tolerance, then the simulation has passed the third and fourth warm-up check. The simulation stays in the warm-up period until ALL FOUR checks have been passed. See Engineering Reference and Output Details document for further explanation and outputs.

Please note--other "convergence tolerance" inputs are required for certain HVAC equipment (unit ventilator, unit heater, window AC, etc.). The purpose and units of these parameters are different from "load convergence tolerance" and "temperature convergence tolerance" in the BUILDING object.

#### 1.4.4.7 Field: Solar Distribution

Setting this value determines how EnergyPlus treats beam solar radiation and reflectances from exterior surfaces that strike the building and, ultimately, enter the zone. There are five choices: **MinimalShadowing**, **FullExterior** and **FullInteriorAndExterior**, **FullExteriorWithReflections**, **FullInteriorAndExteriorWithReflections**.

##### **MinimalShadowing**

In this case, there is no exterior shadowing except from window and door reveals. All beam solar radiation entering the zone is assumed to fall on the floor, where it is absorbed according to the floor's solar absorptance. Any reflected by the floor is added to the transmitted diffuse radiation, which is assumed to be uniformly distributed on all interior surfaces. If no floor is present in the zone, the incident beam solar radiation is absorbed on all interior surfaces according to their absorptances. The zone heat balance is then applied at each surface and on the zone's air with the absorbed radiation being treated as a flux on the surface.

##### **FullExterior, FullExteriorWithReflections**

In this case, shadow patterns on exterior surfaces caused by detached shading, wings, overhangs, and exterior surfaces of all zones are computed. As for MinimalShadowing, shadowing by window and door reveals is also calculated. Beam solar radiation entering the zone is treated as for MinimalShadowing -- All beam solar radiation entering the zone is assumed to fall on the floor, where it is absorbed according to the floor's solar absorptance. Any reflected by the floor is added to the transmitted diffuse radiation, which is assumed to be uniformly distributed on all interior surfaces. If no floor is present in the zone, the incident beam solar radiation is absorbed on all interior surfaces according to their absorptances. The zone heat balance is then applied at each surface and on the zone's air with the absorbed radiation being treated as a flux on the surface.

##### **FullInteriorAndExterior, FullInteriorAndExteriorWithReflections**

This is the same as FullExterior except that instead of assuming all transmitted beam solar falls on the floor the program calculates the amount of beam radiation falling on each surface in the zone, including floor, walls and windows, by projecting the sun's rays through the exterior windows, taking into account the effect of exterior shadowing surfaces and window shading devices.

If this option is used, you should be sure that the surfaces of the zone totally enclose a space. This can be determined by viewing the **plusout.dxf** file with a program like AutoDesk's Volo View Express. You should also be sure that the zone is **convex**. Examples of convex and non-convex zones are shown in Figure 2. The most common non-convex zone is an L-shaped zone. (A formal definition of convex is that any straight line passing through the zone intercepts at most two surfaces.) If the zone's surfaces do not enclose a space or if the zone is not convex you should use Solar Distribution = **FullExterior** instead of **FullInteriorAndExterior**.

If you use **FullInteriorAndExterior** the program will also calculate how much beam radiation falling on the inside of an exterior window (from other windows in the zone) is absorbed by the window, how much is reflected back into the zone, and how much is transmitted to the outside. In this calculation the effect of a shading device, if present, is accounted for.

Figure 2. Illustration of Convex and Non-convex Zones

### Reflection calculations

Note: Using the reflection calculations can be very time-consuming. Even error-prone. As a possible alleviation, you can use the `Output:Diagnostics,DoNotMirrorDetachedShading`; in many cases to get past a fatal error.

If using reflections, the program calculates beam and sky solar radiation that is reflected from exterior surfaces and then strikes the building. These reflecting surfaces fall into three categories:

1) **Shadowing surfaces.** These are surfaces like overhangs or neighboring buildings entered with `Shading:Site`, `Shading:Building`, `Shading:Site:Detailed`, `Shading:Building:Detailed`, `Shading:Overhang`, `Shading:Overhang:Projection`, `Shading:Fin`, `Shading:Fin:Projection` or `Shading:Zone:Detailed` objects. See Figure 3.

These surfaces can have diffuse and/or specular (beam-to-beam) reflectance values that are specified with the `ShadingProperty:Reflectance` object which specifies those parameters. They have a default value of .2 for both visible and diffuse reflection.

2) **Exterior building surfaces.** In this case one section of the building reflects solar radiation onto another section (and vice-versa). See Figure 4.

The building surfaces are assumed to be diffusely reflecting if they are opaque (walls, for example) and specularly reflecting if they are windows or glass doors. The reflectance values for opaque surfaces are calculated by the program from the Solar Absorptance and Visible Absorptance values of the outer material layer of the surface's construction (ref: Material object properties). The reflectance values for windows and glass doors are calculated by the program from the reflectance properties of the individual glass layers that make up surface's construction assuming no shading device is present and taking into account inter-reflections among the layers (ref: Window Properties).

3) **The ground surface.** Reflection from the ground is calculated even if reflections option is not used; but then the ground plane is considered unobstructed, i.e., the shadowing of the ground by the building itself or by obstructions such as neighboring buildings is ignored. Shadowing by the building itself or neighboring buildings is taken into account when the "with reflections" option is used but then the "view factor to ground" is NOT used. This is shown in Figure 5.

Figure 3. Solar reflection from shadowing surfaces. Solid arrows are beam solar radiation; dashed arrows are diffuse solar radiation. (a) Diffuse reflection of beam solar radiation from the top of an overhang. (b) Diffuse reflection of sky solar radiation from the top of an overhang. (c) Beam-to-beam (specular) reflection from the façade of an adjacent highly-glazed building represented by a vertical shadowing surface.

Figure 4. Solar reflection from building surfaces onto other building surfaces. In this example beam solar reflects from a vertical section of the building onto a roof section. The reflection from the window is specular. The reflection from the wall is diffuse.

Figure 5. Shading from building affects beam solar reflection from the ground. Beam-to-diffuse reflection from the ground onto the building occurs only for sunlit areas, A and C, not from shaded area, B.

#### 1.4.4.8 Field: Maximum Number of Warmup Days

This field specifies the number of “warmup” days that might be used in the simulation before “convergence” is achieved. The default number, 25, is usually more than sufficient for this task; however, some complex buildings (with complex constructions) may require more days. If you enter less than 25 as a maximum, that is the number of maximum warmup days that will be used. An error message will occur when the simulation “runs” out of days and has not converged:

```
CheckWarmupConvergence: Loads Initialization, Zone="MAIN ZONE" did not converge after 30 warmup days.
See Warmup Convergence Information in .eio file for details
..Environment(SizingPeriod)="DENVER CENTENNIAL GOLDEN N ANN CLG 1% CONDNS DB=>MWB"
..Max Temp Comparison = 2.06E-002 vs Temperature Convergence Tolerance=0.50 - Pass Convergence
..Min Temp Comparison = 5.95E-003 vs Temperature Convergence Tolerance=0.50 - Pass Convergence
..Max Cool Load Comparison = 9.5082E-002 vs Loads Convergence Tolerance=5.00E-002 - Fail Convergence
```

As noted in the message, there will be more information in the .eio file. (Refer to Output Details document as well for examples.)

You may be able to increase the Maximum Number of Warmup Days and get convergence, but some anomalous buildings may still not converge. Simulation proceeds for x warmup days until “convergence” is reached (see the discussion under the Temperature Convergence Tolerance Value field in this object, just above).

#### 1.4.4.9 Field: Minimum Number of Warmup Days

This field specifies the minimum number of “warmup” days before EnergyPlus will check if it has achieved convergence and can thus start simulating the particular environment (design day, annual run) in question. Research into the minimum number of warmup days indicates that 6 warmup days is generally enough on the minimum end of the spectrum to avoid false predictions of convergence and thus to produce enough temperature and flux history to start EnergyPlus simulation. This was based on a study that used the benchmark reference buildings. It also was observed that convergence performance improved when the number of warmup days increased. As a result, the default value for the minimum warmup days has been set to 6. Users should decrease this number only if they have knowledge that a specific file converges more quickly than 6 days. Users may wish to increase the value in certain situations when, based on the output variables described in the Output Details document, it is determined that EnergyPlus has not converged. While this parameter should be less than the previous parameter, a value greater than the value entered in the field “Maximum Number of Warmup Days” above may be used when users wish to increase warmup days more than the previous field. In this particular case, the previous field will be automatically reset to the value entered in this field and EnergyPlus will run exactly the number of warmup days specified in this field.

An example from an IDF:

```
Building,
  PSI HOUSE DORM AND OFFICES,  !- Name
  36.87000,                    !- North Axis {deg}
  Suburbs,                     !- Terrain
  0.04,                        !- Loads Convergence Tolerance Value
  0.4000000,                  !- Temperature Convergence Tolerance Value {deltaC}
  FullInteriorAndExterior,    !- Solar Distribution
  40,                          !- Maximum Number of Warmup Days
  6;                           !- Minimum Number of Warmup Days
```

#### 1.4.5 SurfaceConvectionAlgorithm:Inside

This input object is used control the choice of models used for surface convection at the inside face of all the heat transfer surfaces in the model. This object sets the selection for convection correlations in a global way. The Zone Inside Convection Algorithm input field in the Zone object may be used to selectively override this value on a zone-by-zone basis. Further, individual surfaces can refine the choice by each surface or surface lists – see object SurfaceProperty:ConvectionCoefficients and object SurfaceProperty:ConvectionCoefficients:MultipleSurface.

##### 1.4.5.1 Field: Algorithm

The model specified in this field is the default algorithm for the inside face all the surfaces.. The key choices are **Simple**, **TARP**, **CeilingDiffuser**, and **AdaptiveConvectionAlgorithm**.

The **Simple** model applies constant heat transfer coefficients depending on the surface orientation.

The **TARP** model correlates the heat transfer coefficient to the temperature difference for various orientations. This model is based on flat plate experiments.

The **CeilingDiffuser** model is a mixed and forced convection model for ceiling diffuser configurations. The model correlates the heat transfer coefficient to the air change rate for ceilings, walls and floors. These correlations are based on experiments performed in an isothermal room with a cold ceiling jet. To avoid discontinuities in surface heat transfer rate calculations, all of correlations have been extrapolated beyond the lower limit of the data set (3 ACH) to a natural convection limit that is applied during the hours when the system is off.

The **AdaptiveConvectionAlgorithm** model is an dynamic algorithm that organizes a large number of different convection models and automatically selects the one that best applies. The adaptive convection algorithm can also be customized using the SurfaceConvectionAlgorithm:Inside:AdaptiveModelSelections input object. These models are explained in detail in the EnergyPlus Engineering Reference Document.

The default is **TARP**.

IDF Example:

```
SurfaceConvectionAlgorithm:Inside,TARP;
```

## 1.4.6 SurfaceConvectionAlgorithm:Outside

Various exterior convection models may be selected for global use. The optional Zone Outside Convection Algorithm input field in the Zone object may be used to selectively override this value on a zone-by-zone basis. Further, individual surfaces can refine the choice by each surface or surface lists – see object SurfaceProperty:ConvectionCoefficients and object SurfaceProperty:ConvectionCoefficients:MultipleSurface.

### 1.4.6.1 Field: Algorithm

The available key choices are **SimpleCombined**, **TARP**, **MoWITT**, **DOE-2**, and **AdaptiveConvectionAlgorithm**.

The **Simple** convection model applies heat transfer coefficients depending on the roughness and windspeed. This is a combined heat transfer coefficient that includes radiation to sky, ground, and air. The correlation is based on Figure 1, Page 25.1 (Thermal and Water Vapor Transmission Data), 2001 ASHRAE Handbook of Fundamentals. Note that if **Simple** is chosen here or in the Zone field and a SurfaceProperty:ConvectionCoefficients object attempts to override the calculation with a different choice, the action will still be one of combined calculation. To change this, you must select one of the other methods for the global default.

All other convection models apply heat transfer coefficients depending on the roughness, windspeed, and terrain of the building's location. These are *convection only* heat transfer coefficients; radiation heat transfer coefficients are calculated automatically by the program.

The **TARP** algorithm was developed for the TARP software and combines natural and wind-driven convection correlations from laboratory measurements on flat plates.

The **DOE-2** and **MoWITT** were derived from field measurements. DOE-2 uses a correlation from measurements by Klems and Yazdanian for rough surfaces. MoWitt uses a correlation from measurements by Klems and Yazdanian for smooth surfaces and, therefore, is most appropriate for windows (see SurfaceProperty:ConvectionCoefficients:MultipleSurface for how to apply to only windows).

The **AdaptiveConvectionAlgorithm** model is a dynamic algorithm that organizes a large number of different convection models and automatically selects the one that best applies. The adaptive convection algorithm can also be customized using the SurfaceConvectionAlgorithm:Outside:AdaptiveModelSelections input object. All algorithms are described more fully in the Engineering Reference.

The default is **DOE-2**.

Note that when the surface is wet (i.e. it is raining and the surface is exposed to wind) then the convection coefficient appears as a very large number (1000) and the surface is exposed to the Outdoor Wet-bulb Temperature rather than the Outdoor Dry-bulb Temperature.

IDF Example:

```
SurfaceConvectionAlgorithm:Outside, AdaptiveConvectionAlgorithm;
```

## 1.4.7 HeatBalanceAlgorithm

The HeatBalanceAlgorithm object provides a way to select what type of heat and moisture transfer algorithm will be used for calculating the performance of the building's surface assemblies. This input controls the overall algorithm used for all the surfaces unless one or more of the SurfaceProperty:HeatTransferAlgorithm:\* objects are used to alter the selection for particular surfaces.

### 1.4.7.1 Field: Algorithm

Four values are allowed to select which solution will be used.

- The **ConductionTransferFunction** selection is a sensible heat only solution and does not take into account moisture storage or diffusion in the construction elements.
- The **MoisturePenetrationDepthConductionTransferFunction** selection is a sensible heat diffusion and an inside surface moisture storage algorithm that also needs additional moisture material property information. Sometimes, this is referred to as the Effective Moisture Penetration Depth or EMPD. See the moisture material property object for additional information and description of outputs:
- MaterialProperty:MoisturePenetrationDepth:Settings
- **Advanced/Research usage:** The **ConductionFiniteDifference** selection is a sensible heat only solution and does not take into account moisture storage or diffusion in the construction elements. This solution technique uses a 1-D finite difference solution in the construction elements. Outputs for the surfaces are described with the material property objects. The Conduction Finite Difference (aka CondFD) property objects are:
- MaterialProperty:PhaseChange
- MaterialProperty:VariableThermalConductivity
- **Advanced/Research usage:** The **CombinedHeatAndMoistureFiniteElement** is a coupled heat and moisture transfer and storage solution. The solution

technique uses a one dimensional finite difference solution in the construction elements and requires further material properties described in the Heat and Moisture Transfer material properties objects. Outputs from the algorithm are described with these objects. The Heat and Moisture Transfer property objects are:

- MaterialProperty:HeatAndMoistureTransfer:Settings
- MaterialProperty:HeatAndMoistureTransfer:SORPTIONIsotherm
- MaterialProperty:HeatAndMoistureTransfer:Suction
- MaterialProperty:HeatAndMoistureTransfer:Redistribution
- MaterialProperty:HeatAndMoistureTransfer:Diffusion
- MaterialProperty:HeatAndMoistureTransfer:ThermalConductivity

#### 1.4.7.2 Field: Surface Temperature Upper Limit

This field is a bit “advanced”. It should only be used when the simulation fails AND you cannot determine a cause for the failure. That is, you receive an error similar to:

```
** Severe ** Temperature out of bounds (202.91) for surface=Wall1
** ~~~ ** in Zone=Zone01
** ~~~ ** Occurrence info=NEW YORK CITY NY SUMMER, 07/21 16:00 - 16:01
** ~~~ ** A temperature out of bounds problem can be caused by several things. The user
** ~~~ ** should check the weather environment, the level of internal gains with respect
** ~~~ ** to the zone, and the thermal properties of their materials among other things.
** ~~~ ** A common cause is a building with no thermal mass -- all materials with
** ~~~ ** Regular-R definitions.
```

And, after careful perusal, you cannot find a solution as suggested in the error description. You may then want to enter a higher number than the default for this field.

#### 1.4.7.3 Field: Minimum Surface Convection Heat Transfer Coefficient Value

This optional field is used to set an overall minimum for the value of the coefficient for surface convection heat transfer (Hc) in W/m2-K. A minimum is necessary for numerical robustness because some correlations for Hc can result in zero values and create numerical problems. This field can be used to support specialized validation testing to suppress convection heat transfer and to investigate the implications of different minimum Hc values. The default is 0.1.

#### 1.4.7.4 Field: Maximum Surface Convection Heat Transfer Coefficient Value

This optional field is used to set an overall maximum for the value of the coefficient for surface convection heat transfer (Hc) in W/m2-K. High Hc values are used in EnergyPlus to approximate fixed surface temperature boundary conditions. This field can be used to alter the accepted range of user-defined Hc values.

And, a default IDF example

```
HeatBalanceAlgorithm,ConductionTransferFunction; ! Solution Algorithm
```

### 1.4.8 HeatBalanceSettings:ConductionFiniteDifference

This object is used to control the behavior of the Conduction Finite Difference algorithm for surface heat transfer. The settings are global and affect how the model behaves for all the surfaces.

#### 1.4.8.1 Field: Difference Scheme

This field determines the solution scheme used by the Conduction Finite Difference model. There are two options CrankNicholsonSecondOrder and FullyImplicitFirstOrder. The CrankNicholsonSecondOrder scheme is second order in time and may be faster. But it can be unstable over time when boundary conditions change abruptly and severely. The FullyImplicitFirstOrder scheme is first order in time and is more stable over time. But it may be slower. The default is FullyImplicitFirstOrder when ConductionFiniteDifference is selected as the Heat Balance Algorithm.

#### 1.4.8.2 Field: Space Discretization Constant

This field controls the how the model determines spatial discretization, or the count of nodes across each material layer in the construction. The model calculates the nominal distance associated with a node,  $\Delta x$ , using

$$\Delta x = \sqrt{C\alpha\Delta t} \quad (1)$$

Where

$\alpha$  is the thermal diffusivity of the material layer, in m<sup>2</sup>/s

$\Delta t$  is the length of the timestep in seconds.

$C$  is a constant set by this field.

The default is 3. Typical values are from 1 to 3. Lower values for this constant lead to more nodes and finer-grained space discretization.

#### 1.4.8.3 Field: Relaxation Factor

The finite difference solver includes under-relaxation for improved stability for interactions with the other surfaces. This input field can optionally be used to modify the starting value for the relaxation factor. Larger numbers may solve faster, while smaller numbers may be more stable. The default is 1.0. If the program detects numerical instability, it may reduce the value entered here to something lower and more stable.

#### 1.4.8.4 Field: Inside Face Surface Temperature Convergence Criteria

The surface heat balance model at the inside face has a numerical solver that uses a convergence parameter for a maximum allowable differences in surface temperature. This field can optionally be used to modify this convergence criteria. The default value is 0.002 and was selected for stability. Lower values may further increase stability at the expense of longer runtimes, while higher values may decrease runtimes but lead to possible instabilities. The units are in degrees Celsius.

An example IDF object follows.

```
HeatBalanceSettings:ConductionFiniteDifference,
  FullyImplicitFirstOrder , !- Difference Scheme
  3.0 , !- Space Discretization Constant
  1.0, !- Relaxation Factor
  0.002 ;!- Inside Face Surface Temperature Convergence Criteria
```

### 1.4.9 ZoneAirHeatBalanceAlgorithm

The ZoneAirHeatBalanceAlgorithm object provides a way to select what type of solution algorithm will be used to calculate zone air temperatures and humidity ratios. This object is an optional object. If the default algorithm is used, this object is not required in an input file.

#### 1.4.9.1 Field: Algorithm

Three choices are allowed to select which solution algorithm will be used. The **ThirdOrderBackwardDifference** selection is the default selection and uses the third order finite difference approximation to solve the zone air energy and moisture balance equations. The **AnalyticalSolution** selection uses the integration approach to solve the zone air energy and moisture balance equations. The **EulerMethod** selection uses the first order finite backward difference approximation to solve the zone air energy and moisture balance equations.

And, a default IDF example is shown below:

```
ZoneAirHeatBalanceAlgorithm, ThirdOrderBackwardDifference; !- Algorithm
```

### 1.4.10 ZoneAirContaminantBalance

The ZoneAirContaminantBalance object provides a way to select which contaminant type will be simulated.

Although carbon dioxide is not considered as an indoor contaminant but it is used as an indicator of indoor air quality object is optional, only required in the input data file if the user wishes to model contaminant concentration levels as part of their simulation.

#### 1.4.10.1 Field: Carbon Dioxide Concentration

Input is Yes or No. The default is No. If Yes, simulation of carbon dioxide concentration levels will be performed. If No, simulation of carbon dioxide concentration levels will not be performed.

#### 1.4.10.2 Field: Outdoor Carbon Dioxide Schedule Name

This field specifies the name of a schedule that contains outdoor air carbon dioxide level values in units of ppm. One source of monthly average CO<sub>2</sub> levels in the atmosphere is available at a NOAA ftpsite as .

#### 1.4.10.3 Field: Generic Contaminant Concentration

Input is Yes or No. The default is No. If Yes, simulation of generic contaminant concentration levels will be performed. If No, simulation of generic contaminant concentration levels will not be performed.

#### 1.4.10.4 Field: Outdoor Generic Contaminant Schedule Name

This field specifies the name of a schedule that contains outdoor air generic contaminant level values in units of ppm.

An IDF example:

ZoneAirContaminantBalance,  
Yes, !- Carbon Dioxide Concentration  
Outdoor CO2 Schedule, !- Outdoor Carbon Dioxide Schedule Name  
Yes, !- Generic Contaminant Concentration  
Generic Contaminant Schedule; !- Outdoor Generic Contaminant Schedule Name

### 1.4.11 Carbon Dioxide Outputs

The following output variables are available when Carbon Dioxide Concentration = Yes.

HVAC,Average,Zone Air CO2 Internal Gain Volume Flow Rate

HVAC,Average,Zone Air CO2 Concentration [ppm]

#### 1.4.11.1 Zone Air CO2 Concentration [ppm]

This output variable represents the carbon dioxide concentration level in parts per million (ppm) for each zone. This is calculated and reported from the Correct step in the Zone Air Contaminant Predictor-Corrector module.

#### 1.4.11.2 Zone Air CO2 Internal Gain Volume Flow Rate [m3/s]

This is the rate of carbon dioxide added to a zone from all types of sources or sinks, in  $\text{m}^3/\text{s}$ .

### 1.4.12 Generic Contaminant Outputs

The following output variable is available when Generic Contaminant Concentration = Yes.

HVAC,Average,Zone Generic Air Contaminant Generation Volume Flow Rate [m3/s]

HVAC,Average,Zone Air Generic Air Contaminant Concentration [ppm]

#### 1.4.12.1 Zone Air Generic Air Contaminant Concentration [ppm]

This output variable represents the generic contaminant concentration level in parts per million (ppm) for each zone. This is calculated and reported from the Correct step in the Zone Air Contaminant Predictor-Corrector module.

#### 1.4.12.2 Zone Generic Air Contaminant Generation Volume Flow Rate [m3/s]

This is the rate of generic air contaminant added (or subtracted) to a zone from all types of sources or sinks.

### 1.4.13 ShadowCalculation

This object is used to control some details of EnergyPlus's solar, shadowing and daylighting models. There are two basic methods available for the calculations. In order to speed up the calculations, shadowing calculations (sun position, etc.) for the default method are performed over a period of days. Note that this value may be very important for determining the amount of sun entering your building and by inference the amount of cooling or heating load needed for maintaining the building. Though termed "shadowing" calculations, it in affect determines the sun position for a particular day in a weather file period simulation. (Each design day will use the date of the design day object). Even though weather file data contains the amount of solar radiation, the internal calculation of sun position will govern how that affects various parts of the building. By default, the calculations are done for every 20 days throughout a weather run period; an average solar position is chosen and the solar factors (such as sunlit areas of surfaces) remain the same for that number of days. When more integrated calculations are needed for controlling dynamic windows or shades, a second method is available where solar calculations are performed at each zone timestep.

#### 1.4.13.1 Field: Calculation Method

This field is used to control how the solar, shading, and daylighting models are calculated with respect to the time of calculations during the simulation. The default and fastest method is selected using the keyword AverageOverDaysInFrequency. A more detailed and slower method can be selected using the keyword DetailedTimestepIntegration. The later method is useful modeling dynamic fenestration and shading surfaces.

#### 1.4.13.2 Field: Calculation Frequency

This numeric field will cause the shadowing calculations to be done periodically using the number in the field as the number of days in each period. This field is only used if the default method AverageOverDaysInFrequency is used in the previous field. Using this field will allow you to synchronize the shadowing calculations with changes in shading devices. Using the default of 20 days in each period is the average number of days between significant changes in solar position angles. For these shadowing calculations, an "average" (over the time period) of solar angles, position, equation of time are also used.

#### 1.4.13.3 Field: Maximum Figures in Shadow Overlap Calculations

This numeric field will allow you to increase the number of figures in shadow overlaps. Due to the shadowing algorithm, the number of shadows in a figure may grow quite large even with fairly reasonable looking structures. Of course, the inclusion of more allowed figures will increase calculation time. Likewise, too few figures may not result in as accurate calculations as you desire.

#### 1.4.13.4 Field: Polygon Clipping Algorithm

This is an advanced feature. Prior to V7, the internal polygon clipping method was a special case of the Weiler-Atherton method. Now, two options are available: **SutherlandHodgman** (default) and **ConvexWeilerAtherton**. Theoretically, Sutherland-Hodgman is a simpler algorithm but it works well in cases where receiving surfaces (of shadows) are non-convex. The Weiler-Atherton implementation is only accurate where both casting and receiving surfaces are convex. Warnings/severe errors are displayed when necessary. More details on polygon clipping are contained in the Engineering Reference.

#### 1.4.13.5 Field: Sky Diffuse Modeling Algorithm

Two choices are available here: **SimpleSkyDiffuseModeling** and **DetailedSkyDiffuseModeling**. **SimpleSkyDiffuseModeling** (default) performs a one-time calculation for sky diffuse properties. This has implications if you have shadowing surfaces with changing transmittance (i.e. not all opaque or not all transparent) during the year. The program checks to see if this might be the case and automatically selects **DetailedSkyDiffuseModeling** if the shading transmittance varies. Even if the transmittance doesn't vary and the option for detailed modeling is used, that option is retained (though it will increase execution time) because you may be using EMS to vary the transmittance. When the detailed modeling is done, there will be a warning posted if the Calculation Frequency (above) is > 1.

In general (and you should also read the previous field description), if shadowing surfaces are used with the transmittance property, the user should be careful to synchronize this calculation with the scheduled occurrence of the transmittance (if any) (or use 1, which will be the most accurate but will cause more time in the calculations).

This field applies to the method called "AverageOverDaysInFrequency." When the method called "DetailedTimestepIntegration" is used the diffuse sky modeling always uses DetailedSkyDiffuseModeling.

Examples of this object in IDF: (note this object must be unique in an IDF)

```
ShadowCalculation,AverageOverDaysInFrequency,1;
```

```
ShadowCalculation, AverageOverDaysInFrequency, 1, , SutherlandHodgman, DetailedSkyDiffuseModeling;
```

Note that the use of "1" in the examples is NOT the same as using DetailedTimestepIntegration – "1" causes daily calculation of the sun position variables but does not change the shadowing calculations more frequently than daily.

#### 1.4.14 Output: Diagnostics

Sometimes, messages only confuse users – especially new users. Likewise, sometimes certain output variables exist for only a certain condition but some take them at face value/name. Some features may be very important but under certain instances cause problems. Thus, we have added the **diagnostic output** object to be able to turn on or off certain messages, variables, and features depending on conditions.

Both fields of the Output:Diagnostics command can accept all the applicable keys. More than one object may be entered.

##### 1.4.14.1 Field: key1, key2

Allowable choices are:

**DisplayAllWarnings** – use this to get all warnings (except the developer warnings "DisplayZoneAirHeatBalanceOffBalance"). This key sets all other display warning values to on.

**DisplayExtraWarnings** – use this to get all extra warnings. An example of an extra warning is when a user enters a ceiling height or volume with the Zone object and EnergyPlus calculates something significantly different based on the entered zone geometry.

**DisplayUnusedSchedules** – use this to have the unused schedules (by name) listed at the end of the simulation.

**DisplayUnusedObjects** – use this to have unused (orphan) objects (by name) listed at the end of the simulation.

**DisplayAdvancedReportVariables** – use this to be able to use certain advanced output variables where the name may be misleading and you need to understand the concepts or reasons for use. If you put in this field, then you will be able to report on these features. They are noted in the descriptions of objects or output variables.

**DisplayZoneAirHeatBalanceOffBalance** – this is a developer diagnostic which you can turn on, if you desire.

**DoNotMirrorDetachedShading** – use this to turn off the automatic mirroring of detached shading surfaces. These surfaces are automatically mirrored so that the user does not need to worry about facing direction of the surface and the shading surface will shade the building as appropriate. Note that Shading:Zone:Detailed surfaces are also mirrored and there is no way to turn that "off".

**DisplayWeatherMissingDataWarnings** – use this to turn on the missing data warnings from the read of the weather file.

**ReportDuringWarmup** – use this to allow reporting during warmup days. This can show you exactly how your facility is converging (or not) during the initial "warmup" days of the simulation. Generally, only developers or expert simulation users would need this kind of detail.

**ReportDetailedWarmupConvergence** – use this to produce detailed reporting (essentially each warmup day for each zone) for warmup convergence.

**ReportDuringHVACSizingSimulation** – use this to allow controlling reporting to SQLite database during sizing period simulations done for HVAC Sizing Simulation. The regular reporting is done in the usual way. This can show details of how advanced sizing adjustments were determined by documenting how the systems operated when doing the intermediate sizing periods. Depending on the number of iterations performed for HVAC Sizing Simulation, there will be a number of sets of results with each set containing all the Sizing Periods.

In IDF use:

```
Output:Diagnostics,  
  DisplayExtraWarnings;
```

#### 1.4.15 Output:DebuggingData

There may be times when a particular input file requires additional debugging. The Output:DebuggingData object may be used to report all available node data (e.g., temperature, mass flow rate, set point, pressure, etc.). The debug data is reported to the DBG text file. The debug file first reports the node number and name, and then all available node information for each zone time step (Ref. Timestep).

The 2 fields of the Output:DebuggingData object can accept either a 1 (turn on) or any other value (turn off). Only one object may be entered.

##### 1.4.15.1 Field: Report Debugging Data

This field turns on debug reporting when a value of 1 is entered. Any other value (usually 0) disables debug reporting.

##### 1.4.15.2 Field: Report During Warmup

This field allows the debug data to be reported during the warmup period. When a value of 1 is entered the data is reported at all times, even during warmup. Any other value (usually 0) disables “reporting at all time” and debug data is only reported for each environment (RunPeriod or SizingPeriod:DesignDay).

In IDF use:

```
Output:DebuggingData,  
  1,1;
```

#### 1.4.16 Output:PreprocessorMessage

The Output:PreprocessorMessage object can be used by preprocessor programs to EnergyPlus for passing certain conditions/errors that might not be detected by scripts executing the EnergyPlus system of programs. This allows EnergyPlus to intercept problems and terminate gracefully rather than the user having to track down the exact conditions.

There is no reason for a user to enter an Output:PreprocessorMessage object but you should encourage interface developers to use this feature. More than one Output:PreprocessorMessage objects may be entered. Of course, no preprocessor message objects are necessary if there is no error information to be passed.

##### 1.4.16.1 Field: Preprocessor Name

The preprocessor name (e.g. EPMacro, ExpandObjects) is entered here. Case is retained so that messages from EnergyPlus look very similar to what a preprocessor would produce.

##### 1.4.16.2 Field: Error Severity

This is the error severity. If Fatal, EnergyPlus will terminate after showing all preprocessor messages.

##### 1.4.16.3 Fields: Message Line 1 through Message Line 10

Each line is limited to 100 characters and an appropriate message can be composed.

An IDF Example:

```
Output:PreprocessorMessage,  
  No Preprocessor Used,      !- preprocessor name  
  Information,               !- error severity  
  Illustrative Message,     !- message line 1  
  No problems for processing; !- message line 2
```

And would appear in output:

```
Preprocessor="No Preprocessor Used" has the following Information messages:  
Illustrative Message  
No problems for processing
```

#### 1.4.17 ZoneCapacitanceMultiplier:ResearchSpecial

This object is an advanced feature that can be used to control the effective storage capacity of the zone. Capacitance multipliers of 1.0 indicate the capacitance is that of the (moist) air in the volume of the specified zone. This multiplier can be increased if the zone air capacitance needs to be increased for stability of the

simulation or to allow modeling higher or lower levels of damping of behavior over time. The multipliers are applied to the base value corresponding to the total capacitance for the zone's volume of air at current zone (moist) conditions.

#### **1.4.17.1 Field: Temperature Capacity Multiplier**

This field is used to alter the effective heat capacitance of the zone air volume. This affects the transient calculations of zone air temperature. Values greater than 1.0 have the effect of smoothing or damping the rate of change in the temperature of zone air from timestep to timestep. Note that sensible heat capacity can also be modeled using internal mass surfaces.

#### **1.4.17.2 Field: Humidity Capacity Multiplier**

This field is used to alter the effective moisture capacitance of the zone air volume. This affects the transient calculations of zone air humidity ratio. Values greater than 1.0 have the effect of smoothing, or damping, the rate of change in the water content of zone air from timestep to timestep.

#### **1.4.17.3 Field: Carbon Dioxide Capacity Multiplier**

This field is used to alter the effective carbon dioxide capacitance of the zone air volume. This affects the transient calculations of zone air carbon dioxide concentration. Values greater than 1.0 have the effect of smoothing or damping the rate of change in the carbon dioxide level of zone air from timestep to timestep.

#### **1.4.17.4 Field: Generic Contaminant Capacity Multiplier**

This field is used to alter the effective generic contaminant capacitance of the zone air volume. This affects the transient calculations of zone air generic contaminant concentration. Values greater than 1.0 have the effect of smoothing or damping the rate of change in the generic contaminant level of zone air from timestep to timestep.

### **1.4.18 SimulationControl**

The input for SimulationControl allows the user to specify what kind of calculations a given EnergyPlus simulation will perform. For instance the user may want to perform one or more of the sizing calculations but not proceed to an annual weather file simulation. Or the user might have all flow rates and equipment sizes already specified and desire an annual weather without any preceding sizing calculations. Sizing runs, even for large projects, are quickly run – they do not add much to the overall simulation time. The SimulationControl input allows all permutations of run selection by means of 5 yes/no inputs.

Only one SimulationControl object is permitted for each EnergyPlus input file. While a SimulationControl is needed to trigger sizing calculations, it is optional for other runs (design days, run periods). The actions will still be shown in the eplusout.eio file (see Output Details and Examples Document).

#### **1.4.18.1 Field: Do Zone Sizing Calculation**

Input is Yes or No. The default is No. Zone Sizing (see Sizing:Zone object) performs a special calculation, using a theoretical ideal zonal system, and determines the zone design heating and cooling flow rates and loads, saving the results in the zone sizing arrays.

#### **1.4.18.2 Field: Do System Sizing Calculation**

Input is Yes or No. The default is No. System Sizing (see Sizing:System object) also performs a special calculation that, to oversimplify, sums up the results of the zone sizing calculation and saves the results in the system sizing arrays for reporting on component size requirements. Thus, in order to perform the system sizing calculations, the zone sizing arrays need to be filled and hence the zone sizing calculations must be performed in the same run. (This requirement is enforced by the program).

#### **1.4.18.3 Field: Do Plant Sizing Calculation**

Input is Yes or No. The default is No. Unlike Zone and System Sizing, Plant Sizing does not use the Zone or System sizing arrays. Plant Sizing uses the Sizing:Plant object fields and data on the maximum component flow rates. The data on component (such as coil) flow rates is saved and made available to the Plant code whether or not component autosizing is performed and whether or not zone sizing and/or system sizing is performed. Therefore, you can specify Plant Sizing without also specifying to do Zone Sizing or System Sizing calculations.

#### **1.4.18.4 Field: Run Simulation for Sizing Periods**

Input is Yes or No. The default is Yes. Yes implies that the simulation will be run on all the included SizingPeriod objects (i.e., SizingPeriod:DesignDay, SizingPeriod:WeatherFileDays, and SizingPeriod:WeatherFileType). Note that each SizingPeriod object constitutes an "environment" and warmup convergence (see earlier topic under the Building object) will occur for each.

#### **1.4.18.5 Field: Run Simulation for Weather File Run Periods**

Input is Yes or No. The default is Yes. Yes implies the simulation will be run on all the included RunPeriod objects. Note that each RunPeriod object constitutes an "environment" and warmup convergence (see earlier topic under the Building object) will occur for each.

#### **1.4.18.6 Field: Do HVAC Sizing Simulation for Sizing Periods**

This field is optional. It can be used to enable certain advanced sizing calculations that rely on simulating the sizing periods to collect information. This is currently only applicable when sizing plant loops using the sizing option called Coincident.

#### 1.4.18.7 Field: Maximum Number of HVAC Sizing Simulation Passes

This field is optional and is only used if the previous field is set to Yes. The HVAC Sizing Simulation approach can use iteration to improve sizing calculations. Each iteration is a Sizing Pass. This field is used to manually place an upper limit the number of passes that the sizing algorithms can use.

An IDF example:

```
SimulationControl,  
No,           !- Do Zone Sizing Calculation  
No,           !- Do System Sizing Calculation  
No,           !- Do Plant Sizing Calculation  
Yes,          !- Run Simulation for Sizing Periods  
Yes;         !- Run Simulation for Weather File Run Periods  
No,           !- Do HVAC Sizing Simulation for Sizing Periods  
2;           !- Maximum Number of HVAC Sizing Simulation Passes
```

#### 1.4.19 ProgramControl

This object is currently disabled. The ProgramControl object can be used to control how the EnergyPlus program executes on the computer. Portions of EnergyPlus have been programmed to use more than one processor, or CPU core, at the same time during a single simulation. This multithreading may not be desirable when running more than one simulation at a time on the same computer (because it can actually run more slowly). This input object is optional and allows controlling the number of threads (or cores, or processors) that EnergyPlus will use so that conflicts can be managed. When this object is used, its input for the number of threads will take precedent over the value of the environment variable “EP\_OMP\_NUM\_THREADS” which is an alternate method of controlling the program’s threading. Since the primary method for OpenMP simulations currently (V7.1 and V7.2) is the interior radiant exchange to solve for inside surface temperatures, EnergyPlus sets the threads to 1 if the nominal number of surfaces is <= 30.

##### 1.4.19.1 Field: Number of Threads Allowed

This field is used to specify a limit on the number of threads EnergyPlus will use. If a zero is entered then the program will set the number of threads to the maximum available on the computer. If the number entered is larger than the number of processors or cores, then the hardware limits will take precedent over this limit.

An example IDF object that sets the program to use only one thread follows.

```
ProgramControl,  
1 ; !- Number of Threads Allowed
```

#### 1.4.20 Meter:Custom

A custom meter allows the user to group variables or meters onto a virtual meter that can be used just like a normal meter created by EnergyPlus. For consistency, the items being grouped must all be similar.

##### 1.4.20.1 Field: Name

This is a user defined name for the custom meter. Names for custom meters cannot duplicate internal meter names.

##### 1.4.20.2 Field: Fuel Type

A fuel type should be specified for the meter. All assignments to this meter will be checked to assure that the same fuel type is used. Additionally, this may be used in other objects (such as the Demand Limiting). Valid choices for this field are:

- Electricity
- NaturalGas
- PropaneGas
- FuelOil#1
- FuelOil#2
- Coal
- Diesel
- Gasoline
- Water

- Generic
- OtherFuel1
- OtherFuel2

Fuel types are generally self-explanatory. Generic is included for convenience when a custom meter is defined that doesn't quite fit the "fuel" categories. See the examples below.

#### **1.4.20.3 Field: group(s) Key Name-Output Variable/Meter Name**

The rest of the object is filled with parameters of the key name/output variable or meter names. When a meter name is used, the key name field is left blank.

#### **1.4.20.4 Field: Key Name #**

A key name field is used when the following field specifies an output variable. If the field is left blank, then all the output variables in the following field are assigned to the meter.

#### **1.4.20.5 Field: Output Variable or Meter Name #**

This field must be a valid output variable name or a valid meter name.

### **1.4.21 Meter:CustomDecrement**

The decrement custom meter is very similar to the custom meter specification but additionally allows a predefined meter to be used as the "source" meter and the remaining items subtract from that predefined meter.

#### **1.4.21.1 Field: Name**

This is a user defined name for the custom meter. Names for custom meters cannot duplicate internal meter names.

#### **1.4.21.2 Field: Fuel Type**

A fuel type should be specified for the meter. All assignments to this meter will be checked to assure that the same fuel type is used. Additionally, this may be used in other objects (such as the Demand Limiting). Valid choices for this field are:

- Electricity
- NaturalGas
- PropaneGas
- FuelOil#1
- FuelOil#2
- Coal
- Diesel
- Gasoline
- Water
- Generic
- OtherFuel1
- OtherFuel2

#### **1.4.21.3 Field: Source Meter Name**

This name specifies the meter that will be used as the main source for the decrement custom meter. The remainder of the fields are subtracted from the value of this meter to create the meter value named above. The Source Meter is not changed in any way by including this custom meter.

#### **1.4.21.4 Field: group(s) Key Name-Output Variable/Meter Name**

The rest of the object is filled with parameters of the key name/output variable or meter names. When a meter name is used, the key name field is left blank.

#### **1.4.21.5 Field: Key Name #**

A key name field is used when the following field specifies an output variable. If the field is left blank, then all the output variables in the following field are assigned to the meter.

#### 1.4.21.6 Field: Output Variable or Meter Name #

This field must be a valid output variable name or a valid meter name. Additionally, it must be contained on the Source Meter. Note that, if an error occurs, only the Variable in error will show – confusing things if what was entered was a meter name.

### 1.4.22 Custom Meter Examples

Details of the Meter:Custom/Meter:CustomDecrement are shown on the Meter Details file.

In the following examples, the custom meters are set up to illustrate the capabilities of custom meters. Custom meter **MyGeneralLights** duplicates the InteriorLights:Electricity meter. Custom meter **MyBuildingElectric** duplicates the Electricity:Building meter (by specifying that meter). Custom Meter (Decrement) **MyBuildingOther** uses the Electricity:Building meter as the source meter and subtracts out the values for MyGeneralLights (aka InteriorLights:Electricity). The resultant value for the MyBuildingOther meter should be equal to the value for the meters Electricity:Building – InteriorLights:Electricity.

```
Meter:Custom,
  MyGeneralLights,      !- Name
  Electricity,          !- Fuel Type
  SPACE1-1,            !- Key Name 1
  Lights Electric Energy, !- Output Variable or Meter Name 1
  SPACE2-1,            !- Key Name 2
  Lights Electric Energy, !- Output Variable or Meter Name 2
  SPACE3-1,            !- Key Name 3
  Lights Electric Energy, !- Output Variable or Meter Name 3
  SPACE4-1,            !- Key Name 4
  Lights Electric Energy, !- Output Variable or Meter Name 4
  SPACE5-1,            !- Key Name 5
  Lights Electric Energy; !- Output Variable or Meter Name 5
```

```
Meter:Custom,
  MyBuildingElectric,  !- Name
  Electricity,         !- Fuel Type
  ,                   !- Key Name \#1
  Electricity:Building; !- Output Variable or Meter Name \#1
```

```
Meter:CustomDecrement,
  MyBuildingOther,    !- Name
  Electricity,        !- Fuel Type
  Electricity:Building, !- Source Meter Name
  ,                  !- Key Name \#1
  MyGeneralLights;   !- Output Variable or Meter Name \#1
```

For an example of “generic” fuel type, one might put the Building Infiltration Heat Loss & Heat Gain on a set of custom meters:

```
Meter:Custom,
  Building Infiltration Heat Loss, !- Name
  Generic,                        !- Fuel Type
  *,                              !- Key Name 1
  Zone Infiltration Total Heat Loss Energy; !- Output Variable Name 1
```

```
Meter:Custom,
  Building Infiltration Heat Gain, !- Name
  Generic,                        !- Fuel Type
  *,                              !- Key Name 1
  Zone Infiltration Total Heat Gain Energy; !- Output Variable Name 1
```

One can then report these values the same way one reports other standard meters.

#### 1.4.23 Simulation Parameter Outputs

These appear in the **eplusout.eio** file. For details of the reporting, please see the Output Details and Examples document.

## 1.5 Group – Compliance Objects

Not necessarily related directly to simulation, the Compliance Object group provides a repository for a group of objects that can be used directly or indirectly in reporting compliance (such as ASHRAE 90.1) to building standards.

## 1.5.1 Compliance:Building

The Compliance:Building object describes parameters related to compliance to building standards, building codes, and beyond energy code programs.

### 1.5.1.1 Field: Building Rotation for Appendix G

Building Rotation for Appendix G allows for the building model to be rotated for use with compliance such as ASHRAE 90.1 Appendix G. Appendix G requires the building to be rotated 0, 90, 180 and 270 degrees and the values averaged to establish baseline energy use. This input works with relative or world coordinate systems.

An example from an IDF:

```
Compliance:Building,
    90;                Building Rotation for Appendix G
```

## 1.6 Group -- Location – Climate – Weather File Access

This group of objects describes the ambient conditions for the simulation.

### 1.6.1 Site:Location

The location class describes the parameters for the building's location. Only one location is allowed. Weather data file location, if it exists, will override any location data in the IDF. Thus, for an annual simulation, a Location does not need to be entered.

#### 1.6.1.1 Field: Name

This alpha field is used as an identifying field in output reports.

#### 1.6.1.2 Field: Latitude

This field represents the latitude (in degrees) of the facility. By convention, North Latitude is represented as positive; South Latitude as negative. Minutes should be represented in decimal fractions of 60. (15' is 15/60 or .25)

#### 1.6.1.3 Field: Longitude

This field represents the longitude (in degrees) of the facility. By convention, East Longitude is represented as positive; West Longitude as negative. Minutes should be represented in decimal fractions of 60. (15' is 15/60 or .25)

#### 1.6.1.4 Field: Time Zone

This field represents the time zone of the facility (relative to Greenwich Mean Time or the 0<sup>th</sup> meridian). Time zones west of GMT (e.g. North America) are represented as negative; east of GMT as positive. Non-whole hours can be represented in decimal (e.g. 6:30 is 6.5).

#### 1.6.1.5 Field: Elevation

This field represents the elevation of the facility in meters (relative to sea level).

Units with their abbreviations are shown in Appendix A. And, as shown in an IDF:

```
Site:Location, DENVER COLORADO,      ! Name
    39.75000    ,      ! Latitude {N+ S-}
   -104.8700    ,      ! Longitude {W- E+}
   -7.000000    ,      ! TimeZoneNumber {GMT+/-}
    1610.26;      ! Elevation {m}
```

Most examples in this document include the comment lines that illustrate each data field's value. However, this is not necessary (though it makes the IDF more readable). The previous example could also be:

```
Site:Location, DENVER COLORADO,39.75,-104.87,-7,1610.26;
```

### 1.6.2 SizingPeriod:DesignDay

The design day input describes the parameters to effect a "design day" simulation, often used for load calculations or sizing equipment. Using the values in these fields, EnergyPlus "creates" a complete days' worth of weather data (air temperatures, solar radiation, etc.) Normal operation uses the default range multipliers as shown in Figure 6 though users may choose to input their own multiplier schedule. Likewise, normal operation specifies one "humidity indicating condition" which is used to calculate the humidity ratio at maximum temperature – this is used as the constant humidity ratio for the entire day. Again, this can be overridden by specifying a relative humidity schedule or requesting generation of an hourly wet-bulb temperature profile. Multiple design days may be specified.

We refer you to the ASHRAE Handbook of Fundamentals for philosophy of what parameters are important for use as "design conditions" in sizing equipment.

In the install, the “design day files” are included for the weather file locations that are included (weatherdata folder). All the design day definitions from the ASHRAE design conditions (latest publication date) are included, grouped by WMO region, on the main web site with the weather data. [http://www.energyplus.gov/cfm/weather\\_data.cfm](http://www.energyplus.gov/cfm/weather_data.cfm) These files are in “macro” form but it is easy to cut and paste the appropriate definition segments. These files include the location information as well as some locations have **RunPeriodControl:DaylightSavingTime** objects.

**1.6.2.1 Field: Name**

This field, like the location name, is used simply for reporting and identification. This name must be unique among the SizingPeriod names entered.

**1.6.2.2 Field: Month**

This numeric field specifies the month. That, in conjunction with the day of the month and location information, determines the current solar position and solar radiation values for each hour of the day.

**1.6.2.3 Field: Day of Month**

This numeric field specifies the day of the month. That, in conjunction with the month and location information, determines the current solar position and solar radiation values for each hour of the day.

**1.6.2.4 Field: Day Type**

This alpha field specifies the day type for the design day. This value indicates which day profile to use in schedules. For further information, see the Schedule discussion later in this document. (ref: Schedule) Note that two of the possible day types are SummerDesignDay (for cooling) and WinterDesignDay (for heating) – allowing the user to customize schedules for the design conditions. That is, for design days tagged with a SummerDesignDay type, you can set schedules to be worst or typical schedules for a cooling season.

**1.6.2.5 Field: Maximum Dry-Bulb Temperature**

This numeric field should contain the day’s maximum dry-bulb temperature in degrees Celsius. (Reference Appendix A of this document for EnergyPlus standard units and abbreviations). The MacroDataSets design day files show extreme temperature for locations as indicated in the ASHRAE HOF design condition tables.

**1.6.2.6 Field: Daily Dry-bulb Temperature Range**

A design day can have a “high” temperature and a “low” temperature (or can be a constant temperature for each hour of the day). If there is a difference between high and low temperatures, this field should contain the difference from the high to the low. EnergyPlus, by default, distributes this range over the 24 hours in the day as shown in the figure below:

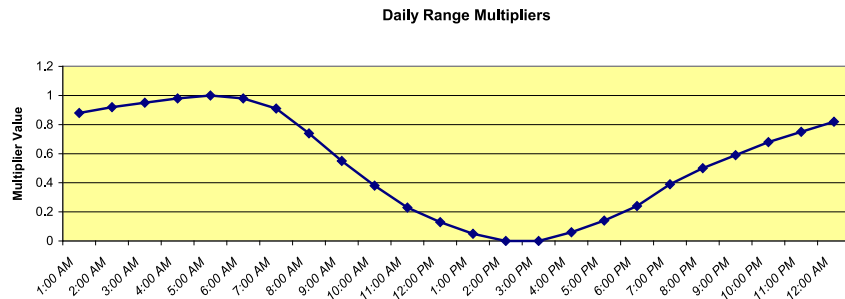

Figure 6. Default Daily range Multiplier for Design Days

The multipliers are taken from the ASHRAE 2009 HOF. More explicitly, EnergyPlus creates an air temperature for each timestep by using the entered maximum dry-bulb temperature in conjunction with the entered daily range and the above multiplier values. The actual equation used is shown below:

$$T_{current} = T_{Max} - T_{range} \cdot T_{Multiplier} \tag{2}$$

where

$T_{current}$ = Air temperature of current Hour of Day

$T_{Max}$ = User supplied Max Dry-bulb Temperature

$T_{range}$ = User supplied Daily Temperature Range

$T_{Multiplier}$ = Range multiplier as shown on the above graph

The range multiplier values represent typical conditions of diurnal temperatures (i.e. the low temperature for the day occurring about 5:00 AM and the maximum temperature for the day occurring about 3:00 PM. Note that EnergyPlus does not shift the profile based on the time of solar noon as is optionally allowed in ASHRAE procedures.

ASHRAE research indicates that dry-bulb and wet-bulb temperatures typically follow the same profile, so EnergyPlus can use the default profile to generate humidity conditions (see Humidity Indicating Type = WetBulbProfileDefaultMultipliers below).

### 1.6.2.7 Field: Dry-Bulb Temperature Range Modifier Type

If you are happy with lows at 5am and highs at 3pm, you can ignore this field. If you want to specify your own temperature range multipliers (see earlier discussion at the Temperature Range field description), you can specify a type here and create a day schedule which you reference in the next field.

If you specify **MultiplierSchedule** in this field, then you need to create a day schedule that specifies a multiplier applied to the temperature range field (above) to create the proper dry-bulb temperature range profile for your design day.

If you specify **DifferenceSchedule** in this field, then you need to create a day schedule that specifies a number to be **subtracted** from dry-bulb maximum temperature for each timestep in the day. Note that numbers in the delta schedules cannot be negative as that would result in a higher maximum than the maximum previously specified.

If you specify **TemperatureProfileSchedule** in this field, then you need to create a day schedule that specifies the actual dry-bulb temperatures throughout the day. You will not need to include a Maximum Dry-Bulb Temperature in that field.

If you leave this field blank or enter **DefaultMultipliers**, then the default multipliers will be used as shown in the “temperature range” field above.

### 1.6.2.8 Field: Dry-Bulb Temperature Range Modifier Day Schedule Name

This field is the name of a **day schedule** (ref. Schedule:Day:Hourly, Schedule:Day:Interval, Schedule:Day:List objects) with the values as specified in the Dry-Bulb Temperature Range Modifier Type field above.

### 1.6.2.9 Field: Humidity Condition Type

The values/schedules indicated here and in subsequent fields create the humidity values in the 24 hour design day conditions profile. Valid choices here are: **WetBulb**, **Dewpoint**, **WetBulbProfileDefaultMultipliers**, **WetBulbProfileDifferenceSchedule**, **WetBulbProfileMultiplierSchedule**, **HumidityRatio**, **Enthalpy**, and **Schedule**.

The Humidity Condition Type fields have interacting uses and units, summarized as follows:

Table 2. Humidity Indicating Field Interactions - Design Day

Humidity Condition Type	Primary Humidity Indicating Field	Humidity Indicating Day Schedule
WetBulb	Wetbulb or DewPoint at Maximum Dry-Bulb	N/A (unused)
DewPoint	Wetbulb or DewPoint at Maximum Dry-Bulb	N/A (unused)
HumidityRatio	Humidity Ratio at Maximum Dry-Bulb	N/A (unused)
Enthalpy	Enthalpy at Maximum Dry-Bulb	N/A (unused)
WetBulbProfileDefaultMultipliers	Wetbulb or DewPoint at Maximum Dry-Bulb	N/A (unused)
WetBulbProfileMultiplierSchedule	Wetbulb or DewPoint at Maximum Dry-Bulb	Fractions of wet-bulb daily range (0 – 1)
WetBulbProfileDifferenceSchedule	Wetbulb or DewPoint at Maximum Dry-Bulb	Difference between maximum and hour/timestep wet-bulb temperature, C
RelativeHumiditySchedule	N/A	Relative humidity (% , 0 – 100)

Humidity conditions over the day are derived as follows:

#### WetBulb, DewPoint, HumidityRatio, or Enthalpy:

These four methods assume constant absolute humidity over the day. Calculate  $W$  = humidity ratio at Maximum Dry-Bulb Temperature and Humidity Indicating Conditions. Derive hourly/timestep humidity conditions from  $W$  and hour/timestep dry-bulb temperature.

#### WetBulbProfileDefaultMultipliers

Generate the wet-bulb temperature profile using Default Daily Range Multiplier for Design Days (shown in Figure 6 above) and Daily Wet-Bulb Temperature Range (below). This method is analogous to DefaultMultiplier generation of the dry-bulb temperature profile and is the procedure recommended in Chapter 14 of ASHRAE 2009 HOF.

#### WetBulbProfileMultiplierSchedule

Generate the wet-bulb profile using multipliers from the Humidity Indicating Day Schedule and Daily Wet-Bulb Temperature Range (below). Analogous to dry-bulb MultiplierSchedule.

## **WetBulbProfileDifferenceSchedule**

Generate the wet-bulb profile by subtracting Humidity Indicating Day Schedule values from the daily maximum wet-bulb temperature (specified in Humidity Indicating Conditions at Maximum Dry-Bulb). Analogous to dry-bulb DifferenceSchedule.

## **RelativeHumiditySchedule**

Hourly relative humidity is specified in Humidity Indicating Day Schedule.

In all cases, the humidity ratio is limited to saturation at the hour/timestep dry-bulb (that is, the dry-bulb temperature is used as specified, but the humidity ratio is modified as needed to be physically possible). Once a valid air state is determined, a complete set of consistent hour/timestep psychrometric values (dewpoint, wet-bulb, and enthalpy) is derived.

### **1.6.2.10 Field: Wetbulb or DewPoint at Maximum Dry-Bulb**

If you choose **Wetbulb** or **Dewpoint** in the Humidity Condition Type field, then this numeric field should contain that value. Note that this field is unnecessary when you put in a humidity indicating day schedule (described later in this section).

### **1.6.2.11 Field: Humidity Condition Day Schedule Name**

Allows specification a day schedule (ref. Schedule:Day:Hourly, Schedule:Day:Interval, Schedule:Day:List objects) of values for relative humidity or wet-bulb profile per Humidity Indicating Type field.

### **1.6.2.12 Field: Humidity Ratio at Maximum Dry-Bulb**

If **HumidityRatio** is chosen for the Humidity Condition Type field, then this numeric field should contain the desired humidity ratio at maximum dry-bulb temperature (units kg Water / kg Dry Air).

### **1.6.2.13 Field: Enthalpy at Maximum Dry-Bulb**

If **Enthalpy** is chosen for the Humidity Condition Type field, then this numeric field should contain the desired enthalpy at maximum dry-bulb temperature (units Joules /kg).

### **1.6.2.14 Field: Daily Wet-Bulb Temperature Range**

The difference between the maximum and minimum wet-bulb temperatures on the design day (Celsius). Used for generating daily profiles of humidity conditions when Humidity Condition Type field (above) is **WetBulbProfileDefaultMultipliers** or **WetBulbProfileMultiplierSchedule**. Values for wet-bulb temperature range are tabulated by month for 5564 locations worldwide on the CD that accompanies the ASHRAE 2009 HOF.

### **1.6.2.15 Field: Barometric Pressure**

This numeric field is the constant barometric pressure (Pascals) for the entire day.

### **1.6.2.16 Field: Wind Speed**

This numeric field is the wind speed in meters/second (constant throughout the day) for the day. The MacroDataSets design day files includes wind speed values (99.6% - heating, 1% cooling) as indicated in ASHRAE HOF design condition tables. But, you should be aware that traditional values for these are 6.7056 m/s (15 mph) for heating and 3.3528 m/s (7 mph) for cooling. A reminder is shown in the comments for the wind speed values. The comments also note the extreme wind speeds from the ASHRAE tables.

### **1.6.2.17 Field: Wind Direction**

This numeric field is the source wind direction in degrees. By convention, winds from the North would have a value of 0., from the East a value of 90.

### **1.6.2.18 Field: Rain Indicator**

This field indicates whether or not the building surfaces are wet. If the value is Yes, then it is assumed that the building surfaces are wet. Wet surfaces may change the conduction of heat through the surface.

### **1.6.2.19 Field: Snow Indicator**

This field indicates whether or not there is snow on the ground. If the value is Yes, then it is assumed there is snow on the ground. Snow on the ground changes the ground reflectance properties.

### **1.6.2.20 Field: Daylight Saving Time Indicator**

This field specifies whether to consider this day to be a Daylight Saving Day. Yes in the field indicates that daylight saving time is operational for this day. Yes essentially adds 1 hour to the scheduling times used in items with schedules.

### 1.6.2.21 Field: Solar Model Indicator

This field allows the user to select **ASHRAEClearSky**, **ASHRAETau**, **ZhangHuang**, or **Schedule** for solar modeling in the calculation of the solar radiation in the design day. ASHRAEClearSky and ZhangHuang use the Clearness value as part of their calculations. ASHRAETau invokes the revised model specified in Chapter 14 of the ASHRAE 2009 HOF and uses Taub and Taud values (below). Technical details of the models are described in the Engineering Reference. The **Schedule** choice allows you to enter schedule values for the day's profile (use the next two fields for the names).

### 1.6.2.22 Field: Beam Solar Day Schedule Name

This field allows the option for you to put in your own day profile of beam solar values (wh/m2). These values will replace the calculated values during design day processing. Only day schedules (ref. Schedule:Day:Hourly, Schedule:Day:Interval, Schedule:Day:List objects) are used here.

### 1.6.2.23 Field: Diffuse Solar Day Schedule Name

This field allows the option for you to put in your own day profile of diffuse solar values (wh/m2). These values will replace the calculated values during design day processing. Only day schedules (ref. Schedule:Day:Hourly, Schedule:Day:Interval, Schedule:Day:List objects) are used here.

### 1.6.2.24 Field: ASHRAE Clear Sky Optical Depth for Beam Irradiance (taub)

Optical depth for beam radiation, used only when Solar Model Indicator is ASHRAETau. See next field.

### 1.6.2.25 Field: ASHRAE Clear Sky Optical Depth for Diffuse Irradiance (taud)

Optical depth for diffuse radiation, used only when Solar Model Indicator is ASHRAETau. Taub and Taud values are tabulated by month for 5564 locations worldwide on the CD that accompanies the ASHRAE 2009 HOF.

### 1.6.2.26 Field: Sky Clearness

If the choice in the Solar Model Indicator field is ASHRAEClearSky or ZhangHuang, then this numeric field should be entered. This value represents the "clearness" value for the day. This value, along with the solar position as defined by the Location information and the date entered for the design day, help define the solar radiation values for each hour of the day. Clearness may range from 0.0 to 1.2, where 1.0 represents a clear sky at sea level. Values greater than 1.0 may be used for high altitude locations. Traditionally, one uses 0.0 clearness for Winter Design Days. Note that this "sky clearness" does not have the same meaning as output variable "Site Daylighting Model Sky Clearness".

Look at the example files 1ZoneUncontrolled\_DDChanges.idf and 1ZoneUncontrolled\_DD2009 for several examples of specifying Design Day inputs.

### 1.6.3 Sizing Period Design Day Outputs

For the schedule fields in the object, several output variables can be used:

- Zone,Average,Sizing Period Site Beam Solar Schedule Value [W/m2]
- Zone,Average,Sizing Period Site Diffuse Solar Schedule Value [W/m2]
- Zone,Average,Sizing Period Site Humidity Condition Schedule Value [%]
- Zone,Average,Sizing Period Site Humidity Condition Schedule Value []
- Zone,Average,Sizing Period Site Drybulb Temperature Range Modifier Schedule Value []
- Zone,Average,Sizing Period Site Drybulb Temperature Range Modifier Schedule Value [deltaC]
- Zone,Average,Sizing Period Site Drybulb Temperature Range Modifier Schedule Value [C]
- Zone,Average,Sizing Period Site Sky Temperature Schedule Value [deltaC]
- Zone,Average,Sizing Period Site Sky Temperature Schedule Value [C]

#### 1.6.3.1 Sizing Period Site Beam Solar Schedule Value [W/m2]

#### 1.6.3.2 Sizing Period Site Diffuse Solar Schedule Value [W/m2]

This schedule value is active when any Design Day objects have / use the solar schedule option. For those objects that don't have this option, the value will be displayed as -999.

#### 1.6.3.3 Sizing Period Site Humidity Condition Schedule Value [%]

#### 1.6.3.4 Sizing Period Site Humidity Condition Schedule Value []

This schedule value is active when any Design Day objects have / use the humidity schedule option. For those objects that don't have this option, the value will be displayed as -999.

#### 1.6.3.5 Sizing Period Site Drybulb Temperature Range Modifier Schedule Value []

#### 1.6.3.6 Sizing Period Site Drybulb Temperature Range Modifier Schedule Value [deltaC]

#### 1.6.3.7 Sizing Period Site Drybulb Temperature Range Modifier Schedule Value [C]

This schedule value is active when any Design Day objects have / use the drybulb temperature range modifier schedule option. For those objects that don't have

this option, the value will be displayed as -999.

#### 1.6.3.8 Sizing Period Site Sky Temperature Schedule Value [deltaC]

#### 1.6.3.9 Sizing Period Site Sky Temperature Schedule Value [C]

This schedule value is active when any Design Day objects have / use the WeatherProperties:SkyTemperature schedule option. For those objects that don't have this option, the value will be displayed as -999.

### 1.6.4 Longer Design Periods

Some features may benefit by using a longer design weather period for sizing or loads calculations. Longer design periods may be created by using the **SizingPeriod:WeatherFileDays** or **SizingPeriod:WeatherFileConditionType** objects. These two objects allow for selections from an attached weather file to be used in the sizing calculations.

#### 1.6.5 SizingPeriod:WeatherFileDays

The SizingPeriod:WeatherFileDays object describes using a selected period from the "attached" weather file to be used in load calculations or sizing equipment. The period selected can be as small as a single day or larger. Multiple periods may be input. While this object may be used for sizing calculations, you should also consider using design days that represent more long term extremes or conditions.

##### 1.6.5.1 Field: Name

This field allows for an assigned name for this run period so it can be tracked easily in sizing and other outputs.

##### 1.6.5.2 Field: Begin Month

This numeric field should contain the starting month number (1=January, 2=February, etc.) for the annual run period desired.

##### 1.6.5.3 Field: Begin Day of Month

This numeric field should contain the starting day of the starting month (must be valid for month) for the annual run period desired.

##### 1.6.5.4 Field: End Month

This numeric field should contain the ending month number (1=January, 2=February, etc.) for the annual run period desired.

##### 1.6.5.5 Field: End Day of Month

This numeric field should contain the ending day of the ending month (must be valid for month) for the annual run period desired.

##### 1.6.5.6 Field: Day of Week for Start Day

For flexibility, the day of week indicated on the weather file can be overridden by this field's value. Valid days of the week (Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday) or special days (SummerDesignDay, WinterDesignDay, CustomDay1, CustomDay2) must be entered in this field. To clarify, this value will be used as the Start Day (type) for this sizing period. When weekdays are used, each subsequent day in the period will be incremented. When SummerDesignDay, WinterDesignDay, CustomDay1, CustomDay2 – are used, the day type will be applied for the entire period.

##### 1.6.5.7 Field: Use Weather File Daylight Saving Period

Weather files can contain indicators of Daylight Saving Period days. For flexibility, you may want to ignore these designations on the weather file. This field should contain the word **Yes** if you will accept daylight saving period days as contained on the weather file (note: not all weather files may actually have this period) or **No** if you wish to ignore Daylight Saving Period days that may be on the weather file.

Note that a blank or null field in this field will indicate **Yes**.

##### 1.6.5.8 Field: Use Weather File Rain and Snow Indicators

Weather files can contain "rain" and "snow" indicators. (EPW field "Present Weather Codes" – described in the AuxiliaryPrograms document). In turn, rain indicates wet surfaces which changes the film convection coefficient for the surface. Other models may use rain as well (Ground Heat Exchangers). Snow indicators can change the ground reflectance if there is snow on the ground. Entering "**Yes**" in this field allows the weather file conditions to represent "Rain" and "Snow"; entering "**No**" in the field "turns off" the rain/snow indicators for this period. You might use this to be able to compare two "same location" weather files of different years, origins, etc.

IDF Example:

```
SizingPeriod:WeatherFileDays,  
    Summer including Extreme Summer days,    !- Name
```

```

7,18,7,25,           !- Begin/end Day/Month
SummerDesignDay,    !- Day type
No,                 !- Use Weather File Daylight Saving Period
No;                 !- Use Weather File Rain and Snow Indicators

```

```

SizingPeriod:WeatherFileDays,
  Winter including Extreme Winter days, !- Name
  1,25,2,1,           !- Begin/end Day/Month
  WinterDesignDay,    !- Day type
  No,                 !- Use Weather File Daylight Saving Period
  No;                 !- Use Weather File Rain and Snow Indicators

```

## 1.6.6 SizingPeriod:WeatherFileConditionType

When the EPW files are created, a heuristic procedure identifies extreme and typical periods in the actual weather file. This object will allow one of those periods to be selected for sizing or load calculations (typically). Multiple objects may be input. While this object may be used for sizing calculations, you should also consider using design days that represent more long term extremes or conditions.

### 1.6.6.1 Field: Name

This field allows for an assigned name for this run period so it can be tracked easily in sizing and other outputs.

### 1.6.6.2 Field: Period Selection

This field allows the generic period calculated from the weather file to be selected for this run period. It is not completely generic as there may be extreme cold periods in some weather files but extreme wet periods (tropical) in others. Not all weather files have all of the valid choices. The choices for this field are:

- SummerExtreme
- SummerTypical
- WinterExtreme
- WinterTypical
- AutumnTypical
- SpringTypical
- WetSeason
- DrySeason
- NoDrySeason
- NoWetSeason
- TropicalHot
- TropicalCold

### 1.6.6.3 Field: Day of Week for Start Day

For flexibility, the day of week indicated on the weather file can be overridden by this field's value. Valid days of the week (Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday) or special days (SummerDesignDay, WinterDesignDay, CustomDay1, CustomDay2) must be entered in this field. To clarify, this value will be used as the Start Day (type) for this sizing period. When weekdays are used, each subsequent day in the period will be incremented. When SummerDesignDay, WinterDesignDay, CustomDay1, CustomDay2 – are used, the day type will be applied for the entire period.

### 1.6.6.4 Field: Use Weather File Daylight Saving Period

Weather files can contain indicators of Daylight Saving Period days. For flexibility, you may want to ignore these designations on the weather file. This field should contain the word **Yes** if you will accept daylight saving period days as contained on the weather file (note: not all weather files may actually have this period) or **No** if you wish to ignore Daylight Saving Period days that may be on the weather file.

Note that a blank or null field in this field will indicate **Yes**.

### 1.6.6.5 Field: Use Weather File Rain and Snow Indicators

Weather files can contain "rain" and "snow" indicators. (EPW field "Present Weather Codes" – described in the AuxiliaryPrograms document). In turn, rain indicates wet surfaces which changes the film convection coefficient for the surface. Other models may use rain as well (Ground Heat Exchangers). Snow indicators can change the ground reflectance if there is snow on the ground. Entering "**Yes**" in this field allows the weather file conditions to represent "Rain" and

“Snow”; entering “No” in the field “turns off” the rain/snow indicators for this period. You might use this to be able to compare two “same location” weather files of different years, origins, etc.

IDF Example:

```
SizingPeriod:WeatherFileConditionType,  
Extreme Summer Weather Period for Design,  !- Name  
SummerExtreme,                             !- Period Selection  
SummerDesignDay,                           !- Day Type  
No,                                         !- Use Weather File Daylight Saving Period  
No;                                         !- Use Weather File Rain and Snow Indicators
```

```
SizingPeriod:WeatherFileConditionType,  
Extreme Winter Weather Period for Design,  !- Name  
WinterExtreme,                             !- Period Selection  
WinterDesignDay,                           !- Day Type  
No,                                         !- Use Weather File Daylight Saving Period  
No;                                         !- Use Weather File Rain and Snow Indicators
```

## 1.6.7 RunPeriod

The RunPeriod object describes the elements necessary to create a weather file simulation. Multiple run periods may be input. EnergyPlus accepts weather files in the special EnergyPlus weather format (described briefly below this document and in more detail in the Auxiliary Programs document). These files can describe Daylight Saving Time periods as well as holidays within their definitions. The RunPeriod object allows the user to override the use of both the Daylight Saving Period (i.e. use or ignore) and holidays that are embedded within the weather file. Note that the weather file also may contain design condition information, typical and extreme period information, ground temperatures based on air temperature calculations.

### 1.6.7.1 Field: Name

This optional field allows the RunPeriod to be named for output reporting. When left blank, the weather file location name is used. Note that the weather file location name will be appended to this name in tabular/summary reports.

### 1.6.7.2 Field: Begin Month

This numeric field should contain the starting month number (1=January, 2=February, etc.) for the annual run period desired.

### 1.6.7.3 Field: Begin Day of Month

This numeric field should contain the starting day of the starting month (must be valid for month) for the annual run period desired.

### 1.6.7.4 Field: End Month

This numeric field should contain the ending month number (1=January, 2=February, etc.) for the annual run period desired.

### 1.6.7.5 Field: End Day of Month

This numeric field should contain the ending day of the ending month (must be valid for month) for the annual run period desired.

### 1.6.7.6 Field: Day of Week for Start Day

For flexibility, the day of week indicated on the weather file can be overridden by this field’s value. Valid days of the week (Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday) must be entered in this field. To clarify, this value will be used as the Start Day (type) for this run period and subsequent days will be implemented. If a blank or UseWeatherFile is entered here, then the starting day type will be calculated from the weather file (ref: Auxiliary Programs document about Data Periods).

### 1.6.7.7 Field: Use Weather File Holidays and Special Days

Weather files can contain holiday designations or other kinds of special days. These day types cause a corresponding day’s schedule (see SCHEDULE definitions below) to be used during that day. This field should contain the word **Yes** if holidays or other special days indicated directly on the weather file should retain their “day type” or **No** if holidays or other special days on the weather file should be ignored. Reference the RunPeriodControl:SpecialDays object below to enter your own special days and holidays.

Note that a blank or null field in this field will indicate **Yes**.

### 1.6.7.8 Field: Use Weather File Daylight Saving Period

Weather files can contain indicators of Daylight Saving period days. For flexibility, you may want to ignore these designations on the weather file. This field should contain the word **Yes** if you will accept daylight saving period days as contained on the weather file (note: not all weather files may actually have this period) or **No** if you wish to ignore Daylight Saving period days that may be on the weather file.

Note that a blank or null field in this field will indicate **Yes**.

#### 1.6.7.9 Field: Apply Weekend Holiday Rule

In some countries (notably the US), when holidays fall on weekends, they are often observed on a weekday close to the holiday day. (Usually if the specific day falls on a Saturday, the observed day is Friday; if on a Sunday, the observed day is Monday). EnergyPlus will represent this custom using the value in this field. If the field is **Yes**, then specific date holidays that have a duration of one day, will be “observed” on the Monday after the day. (Specific day holidays are such as January 1 – a day-month combination). If the field is blank or **No**, then the holiday will be shown on the day-month as entered. As this option is listed at the RunPeriod, all applicable special days for the run will use the rule – there is no override for individual special days.

Note that a blank or null field in this field will indicate **No**.

Note: EnergyPlus processed weather files available on the EnergyPlus web site: [http://www.energyplus.gov/cfm/weather\\_data.cfm](http://www.energyplus.gov/cfm/weather_data.cfm) have neither special days specified nor daylight saving period. However, DDD (Design Day) files produced from the ASHRAE Design Conditions that accompany the EPW files may include a DaylightSavingPeriod object for certain locations.

#### 1.6.7.10 Field: Use Weather File Rain Indicators

Weather files can contain “rain” indicators. (EPW field “Present Weather Codes” – described in the AuxiliaryPrograms document). In turn, rain indicates wet surfaces which changes the film convection coefficient for the surface. Other models may use rain as well (Ground Heat Exchangers). Entering **Yes** in this field allows the weather file conditions to represent “Rain”; entering **No** in the field “turns off” the rain indicator for this period. You might use this to be able to compare two “same location” weather files of different years, origins, etc.

#### 1.6.7.11 Field: Use Weather File Snow Indicators

Weather files can contain “snow” indicators. (EPW field “Snow Depth” > 0 indicates “Snow on the ground”). In turn, snow changes the reflectivity of the ground and cascades changes of this reflectivity. Entering **Yes** in this field allows the weather file conditions to represent “Snow”; entering **No** in the field “turns off” the snow indicator for this period. You might use this to be able to compare two “same location” weather files of different years, origins, etc.

#### 1.6.7.12 Field: Number of Times Runperiod to be Repeated

This numeric field represents the number of times (usually years) the simulation has to be carried out in a multi runperiod simulation. The default value is set to 1. The number of years of simulation, in case of a Ground Loop Heat Exchanger (GLHE) simulation, should be equal to the length of simulation field in GLHE object. Note that you can specify a number of simulation years with a shorter run period (e.g. 1 week) and EnergyPlus will repeat the simulation of the shorter run period for that many times. Note that repeating will work with any weather file that contains the start date and end date in a “Data Period” (refer to Auxiliary Programs document for more documentation on weather file contents).

#### 1.6.7.13 Field: Increment Day of Week on Repeat

When repeating RunPeriods (see previous field), you can choose to increment the day of week at the end of the period to have a more continuous day type. Enter **Yes** to increment the day of the week (default). An entry of **No** will keep the same day of week values as in the first time through.

#### 1.6.7.14 Field: Start Year

When repeating a period, you might (for whatever reason), choose to have a specific year as a starting year. Enter an appropriate 4 digit year in this field. Refer to Auxiliary Programs document for more documentation on weather file contents, particularly in using leap year data (or not) within weather files.

And, as shown in an IDF:

```
RunPeriod, ! Winter Simulation
  Winter Simulation, !- Name
  12, !- Begin Month
  1, !- Begin Day of Month
  3, !- End Month
  31, !- End Day of Month
  UseWeatherFile, !- Day of Week for Start Day
  Yes, !- Use Weather File Holidays and Special Days
  Yes, !- Use Weather File Daylight Saving Period
  No, !- Apply Weekend Holiday Rule
  Yes, !- Use Weather File Rain Indicators
  Yes; !- Use Weather File Snow Indicators
```

```
! Multiple year simulation example
RunPeriod,
  Multiple Years, !- Name
  1, !- Begin Month
  1, !- Begin Day of Month
  12, !- End Month
```

```

31,    !- End Day of Month
UseWeatherFile, !- Day of Week for Start Day
Yes,   !- Use Weather File Holidays and Special Days
Yes,   !- Use Weather File Daylight Saving Period
No,    !- Apply Weekend Holiday Rule
Yes,   !- Use Weather File Rain Indicators
Yes,   !- Use Weather File Snow Indicators
3;     !- Number of Times Runperiod to be Repeated

```

## 1.6.8 RunPeriod:CustomRange

The RunPeriod:CustomRange object describes the elements necessary to use a specially crafted (likely multiple year) weather file in a simulation. These kinds of weather files and simulations might be useful for matching utility periods or simulating several years of differing weather data. Multiple run periods may be input. EnergyPlus accepts weather files in the special EnergyPlus weather format (described briefly below this document and in more detail in the Auxiliary Programs document). In order to effectively use this object, however, you will need to use a text editor (EnergyPlus weather files are simple text files) or possibly a spreadsheet program and then save to a csv (comma separated variable) file. Weather files can describe Daylight Saving Time periods as well as holidays within their definitions. The RunPeriod:CustomRange object allows the user to override the use of both the Daylight Saving Period (i.e. use or ignore) and holidays that are embedded within the weather file. Note that the weather file also may contain design condition information, typical and extreme period information, ground temperatures based on air temperature calculations.

### 1.6.8.1 Field: Name

This optional field allows the RunPeriod to be named for output reporting. When left blank, the weather file location name is used. Note that the weather file location name will be appended to this name in tabular/summary reports.

### 1.6.8.2 Field: Begin Month

This numeric field should contain the starting month number (1=January, 2=February, etc.) for the annual run period desired.

### 1.6.8.3 Field: Begin Day of Month

This numeric field should contain the starting day of the starting month (must be valid for month) for the annual run period desired.

### 1.6.8.4 Field: Begin Year

This numeric field should contain the beginning year for the custom range. Though all EnergyPlus (EPW) weather files contain a year/year field, the RunPeriod object does not use this field (previous object). The **RunPeriod:CustomRange** object causes the program to look specifically for the begin date specified by these three fields (i.e. Begin Month, Begin Day of Month, Begin Year).

### 1.6.8.5 Field: End Month

This numeric field should contain the ending month number (1=January, 2=February, etc.) for the annual run period desired.

### 1.6.8.6 Field: End Day of Month

This numeric field should contain the ending day of the ending month (must be valid for month) for the annual run period desired.

### 1.6.8.7 Field: End Year

This numeric field should contain the end year for the custom range. Though all EnergyPlus (EPW) weather files contain a year/year field, the RunPeriod object does not use this field (previous object). The **RunPeriod:CustomRange** object causes the program to look specifically for the end date specified by these three fields (i.e. End Month, End Day of Month, End Year).

### 1.6.8.8 Field: Day of Week for Start Day

For flexibility, the day of week indicated on the weather file can be overridden by this field's value. Valid days of the week (Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday) must be entered in this field. To clarify, this value will be used as the Start Day (type) for this run period and subsequent days will be implemented. If a blank or UseWeatherFile is entered here, then the starting day type will be calculated from the weather file (ref: Auxiliary Programs document about Data Periods).

### 1.6.8.9 Field: Use Weather File Holidays and Special Days

Weather files can contain holiday designations or other kinds of special days. These day types cause a corresponding day's schedule (see SCHEDULE definitions below) to be used during that day. This field should contain the word **Yes** if holidays or other special days indicated directly on the weather file should retain their "day type" or **No** if holidays or other special days on the weather file should be ignored. Reference the RunPeriodControl:SpecialDays object below to enter your own special days and holidays.

Note that a blank or null field in this field will indicate **Yes**.

#### 1.6.8.10 Field: Use Weather File Daylight Saving Period

Weather files can contain indicators of Daylight Saving period days. For flexibility, you may want to ignore these designations on the weather file. This field should contain the word **Yes** if you will accept daylight saving period days as contained on the weather file (note: not all weather files may actually have this period) or **No** if you wish to ignore Daylight Saving period days that may be on the weather file.

Note that a blank or null field in this field will indicate **Yes**.

#### 1.6.8.11 Field: Apply Weekend Holiday Rule

In some countries (notably the US), when holidays fall on weekends, they are often observed on a weekday close to the holiday day. (Usually if the specific day falls on a Saturday, the observed day is Friday; if on a Sunday, the observed day is Monday). EnergyPlus will represent this custom using the value in this field. If the field is **Yes**, then specific date holidays that have a duration of one day, will be “observed” on the Monday after the day. (Specific day holidays are such as January 1 – a day-month combination). If the field is blank or **No**, then the holiday will be shown on the day-month as entered. As this option is listed at the RunPeriod, all applicable special days for the run will use the rule – there is no override for individual special days.

Note that a blank or null field in this field will indicate **No**.

Note: EnergyPlus processed weather files available on the EnergyPlus web site:[http://www.energyplus.gov/cfm/weather\\_data.cfm](http://www.energyplus.gov/cfm/weather_data.cfm) have neither special days specified nor daylight saving period. However, DDY (Design Day) files produced from the ASHRAE Design Conditions that accompany the EPW files may include a DaylightSavingPeriod object for certain locations.

#### 1.6.8.12 Field: Use Weather File Rain Indicators

Weather files can contain “rain” indicators. (EPW field “Present Weather Codes” – described in the AuxiliaryPrograms document). In turn, rain indicates wet surfaces which changes the film convection coefficient for the surface. Other models may use rain as well (Ground Heat Exchangers). Entering “**Yes**” in this field allows the weather file conditions to represent “Rain”; entering “**No**” in the field “turns off” the rain indicator for this period. You might use this to be able to compare two “same location” weather files of different years, origins, etc.

#### 1.6.8.13 Field: Use Weather File Snow Indicators

Weather files can contain “snow” indicators. (EPW field “Snow Depth” > 0 indicates “Snow on the ground”). In turn, snow changes the reflectivity of the ground and cascades changes of this reflectivity. Entering “**Yes**” in this field allows the weather file conditions to represent “Snow”; entering **No** in the field “turns off” the snow indicator for this period. You might use this to be able to compare two “same location” weather files of different years, origins, etc.

### 1.6.9 RunPeriodControl:SpecialDays

For weather file run periods, special day run periods can be described. These will always be in effect for the selected days in the run period. Depending on the Use Special Days value in the RunPeriod:\* object(s), these can augment any special days included on the weather file.

Note: EnergyPlus processed weather files available on the EnergyPlus web site:[http://www.energyplus.gov/cfm/weather\\_data.cfm](http://www.energyplus.gov/cfm/weather_data.cfm) have neither special days specified nor daylight saving period. However, DDY (Design Day) files produced from the ASHRAE Design Conditions that accompany the EPW files may include a DaylightSavingPeriod object for certain locations.

#### 1.6.9.1 Field: Name

This alpha field is the title for the special day period. It must be unique among all the special day period objects entered.

#### 1.6.9.2 Field: Start Date

This field is the starting date for the special day period. Dates in this field can be entered in several ways as shown in the accompanying table:

Table 3. Date Field Interpretation

Field Contents	Interpretation
<number> / <number>	Month / Day
<number> Month	Day and Month
Month <number>	Day and Month
<number> Weekday in Month	Numbered weekday of month
Last Weekday In Month	Last weekday of month

In the table, Month can be one of (January, February, March, April, May, June, July, August, September, October, November, December). Abbreviations of the first three characters are also valid.

In the table, Weekday can be one of (Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday). Abbreviations of the first three characters are also valid.

### 1.6.9.3 Field: Duration

This numeric field specifies how long (number of days) the special day period lasts.

### 1.6.9.4 Field: Special Day Type

This alpha field designates the “day type” for schedule use during the special period. It must be one of (Holiday, SummerDesignDay, WinterDesignDay, CustomDay1, CustomDay2).

An example in the IDF would be:

```
RunPeriodControl:SpecialDays, President's Day, 3rd Monday in February,1,Holiday;  
RunPeriodControl:SpecialDays, Thanksgiving, 4th Thursday in November, 1,Holiday;  
RunPeriodControl:SpecialDays, Halloween, 10/31, 1, Holiday;  
RunPeriodControl:SpecialDays, Vacation, 5/1, 14, CustomDay1;
```

## 1.6.10 RunPeriodControl:DaylightSavingTime

Similar to a special day period, a daylight saving period may be entered to be applied to weather file run periods. These will always be in effect, regardless of the value entered on the RunPeriod object. Note that this period will always override any daylight saving period specified in a weather file.

Note: EnergyPlus processed weather files available on the EnergyPlus web site:[http://www.energyplus.gov/cfm/weather\\_data.cfm](http://www.energyplus.gov/cfm/weather_data.cfm) have neither special days specified nor daylight saving period.

**Note: For EnergyPlus Output:Variable and Output:Meter reporting, the time stamps are always in standard time. When daylight saving time is active, scheduled loads and controls will shift one hour relative to standard time.**

### 1.6.10.1 Field: Start Date

This is the starting date of the daylight saving period. Note that it can be entered in several formats as shown in Table 3. Date Field Interpretation.

### 1.6.10.2 Field: End Date

This is the ending date of the daylight saving period. Note that it can be entered in several formats as shown in Table 3. Date Field Interpretation.

And in the IDF:

```
! U.S. Standard for Daylight Saving  
RunPeriodControl:DaylightSavingTime,2nd Sunday in March, 1st Sunday in November; !2007  
! Brazil standard  
RunPeriodControl:DaylightSavingTime,1st Sunday in October, Last Sunday in February;  
! European Standard  
RunPeriodControl:DaylightSavingTime, Last Sunday in March, Last Sunday in October;  
! Syria Standard  
RunPeriodControl:DaylightSavingTime, 4/1, 10/1;
```

Of course, these could not all appear in the same IDF as only one DaylightSavingPeriod object per input file is allowed. More information on Daylight Saving Periods can be seen on the web at: <http://www.webexhibits.org/daylightsaving/>. The ASHRAE Handbook of Fundamentals [ASHRAE 2005] also contains information about daylight saving periods and their climatic information now includes start and end dates for many locations.

## 1.6.11 WeatherProperty:SkyTemperature

Sky Temperature, or radiative sky temperature, is internally calculated by EnergyPlus using an algorithm using horizontal infrared radiation from sky, cloudiness factors and current temperature. The algorithm is fully described in the Engineering Reference document. For flexibility, the following object can be entered to override the internal calculations. Much of the literature describes the sky temperature as relative to either drybulb or dewpoint temperature.

### 1.6.11.1 Field: Name

This name references an existing design period (i.e., SizingPeriod:DesignDay, SizingPeriod:WeatherFileDays, or SizingPeriod:WeatherFileConditionType) or run period (by name or blank for all run periods).

### 1.6.11.2 Field: Calculation Type

Allowable entries here are: **ScheduleValue**, **DifferenceScheduleDryBulbValue**, or **DifferenceScheduleDewPointValue**. In each case the following field must specify a valid schedule name. **ScheduleValue** – the values in the schedule are used as the sky temperature. **DifferenceScheduleDryBulbValue** – the values in the schedule are used as a difference to the drybulb temperature value (+values would then be greater than the drybulb temperature, -values would then be less than the drybulb temperature) for the resulting sky temperature value. **DifferenceScheduleDewPointValue** – the values in the schedule are used as a difference to the dewpoint temperature value (+values would then be greater than the dewpoint temperature, -values would then be less than the dewpoint temperature) for the resulting sky temperature value.

### 1.6.11.3 Field: ScheduleName

This field specifies a schedule name to accomplish the sky temperature calculation from the previous field. A Schedule:Day:\* (i.e., Schedule:Day:Hourly, Schedule:Day:Interval, Schedule:Day:List) should be specified if the name in the name field matches a SizingPeriod:DesignDay object. If the name is one of the weather file period specifications (i.e. matches a SizingPeriod:WeatherFileDays, SizingPeriod:WeatherFileConditionType or RunPeriod), then the schedule name must match a full year schedule (i.e. Schedule:Year, Schedule:Compact, Schedule:File, or Schedule:Constant).

An example of IDF usage (with DesignDay):

```
SizingPeriod:DesignDay,
DENVER_STAPLETON Ann Clg 1% Sky Temperature modifier, !- Name
32.6, !- Maximum Dry-Bulb Temperature {C}
15.2, !- Daily Temperature Range {deltaC}
15.5, !- Humidity Indicating Conditions at Maximum Dry-Bulb
83411., !- Barometric Pressure {Pa}
4, !- Wind Speed {m/s}
120, !- Wind Direction {deg}
1.00, !- Sky Clearness
0, !- Rain Indicator
0, !- Snow Indicator
25, !- Day of Month
7, !- Month
SummerDesignDay, !- Day Type
0, !- Daylight Saving Time Indicator
WetBulb, !- Humidity Indicating Type
, !- Relative Humidity Day Schedule Name
deltaschedule, !- Dry-Bulb Temperature Range Modifier Type
temp range deltas; !- Dry-Bulb Temperature Range Modifier Schedule Name
```

```
WeatherProperty:SkyTemperature,
DENVER_STAPLETON Ann Clg 1% Sky Temperature modifier, !- Name
ScheduleValue, !- Calculation Type
DaySchedule5; !- Schedule Name
```

```
Schedule:Day:Interval,
DaySchedule5, !- Name
Temperature, !- Schedule Type Limits Name
Yes, !- Interpolate to Timestep
until: 24:00, !- Time 1
5; !- Value Until Time 1
```

## 1.6.12 Site:WeatherStation

The Site:WeatherStation object is used to specify the measurement conditions for the climatic data listed in the weather file. These conditions indicate the height above ground of the air temperature sensor, the height above ground of the wind speed sensor, as well as coefficients that describe the wind speed profile due to the terrain surrounding the weather station. There are necessary correlations between the entries for this object and some entries in the Building object, specifically the **Terrain** field.

Weather stations throughout the world (ref: WMO – World Meteorological Organization) take their measurements at standard conditions:

- Air temperature is measured at approximately 1.5 m above ground
- Wind speed is measured at 10 m above ground
- Weather station is in a flat, open field with little protection from the wind.

When using weather data from standard sources (e.g., TMY2, IWEC, TMY, or ASHRAE design day data), it is not necessary to use the **Site:WeatherStation** object. However, if you are using custom weather data or real-time weather data, you may need to read and understand the concepts in the **Site:WeatherStation** object.

The measurement conditions at the weather station (i.e., the weather file) are used by EnergyPlus in conjunction with the **Terrain** field of the **Building** object, or optionally with the **Site:HeightVariation** object (see below), to calculate the local variation in atmospheric properties as a function of height above ground. Outdoor air temperature decreases with height, while wind speed increases with height. The algorithms for this calculation are in the Engineering Reference.

The **Site:WeatherStation** object is useful when working with a custom weather file that includes data that were not measured at the WMO standard conditions. For example, the weather data could be measured on site, or on the roof top of a nearby building. The wind speed profile coefficients can be estimated from the table below or calculated beforehand using more sophisticated techniques such as CFD modeling of the weather station terrain.

Table 4. Wind Speed Profile Coefficients (ASHRAE Fundamentals 2005).

Terrain Description	Exponent	Bounhary Layer Thickness (m)
Flat, open country	0.14	270
Rough, wooded		

country	0.22	370
Towns and cities	0.33	460
Ocean	0.10	210
Urban, industrial, forest	0.22	370

If the **Site:WeatherStation** object is omitted from the input file, the WMO standard measurement conditions are assumed.

#### 1.6.12.1 Field: Wind Sensor Height Above Ground

The height [m] above ground for the wind speed sensor.

#### 1.6.12.2 Field: Wind Speed Profile Exponent

The wind speed profile exponent for the terrain surrounding the weather station. The exponent can be estimated from the table above or calculated beforehand using more sophisticated techniques, such as CFD modeling of the weather station terrain.

#### 1.6.12.3 Field: Wind Speed Profile Boundary Layer Thickness

The wind speed profile boundary layer thickness [m] for the terrain surrounding the weather station. The boundary layer can be estimated from the table above or calculated beforehand using more sophisticated techniques, such as CFD modeling of the weather station terrain.

#### 1.6.12.4 Field: Air Temperature Sensor Height Above Ground

The height [m] above ground for the air temperature sensor.

For example, if you are using weather data measured on the top of your building, you should set the *Wind Sensor Height Above Ground* and the *Air Temperature Sensor Height Above Ground* to equal the height of your building (say 30 m). The *Wind Speed Profile Exponent* and *Wind Speed Profile Boundary Layer Thickness* should be set to match the values associated with the *Terrain* field of the **Building** object, or the equivalent fields of the **Site:HeightVariation** object.

Or, in IDF terms, with a building in a town or city:

```
Site:WeatherStation,
  30, !- Wind Sensor Height Above Ground {m}
  0.33, !- Wind Speed Profile Exponent {}
  460, !- Wind Speed Profile Boundary Layer Thickness {m}
  30; !- Air Temperature Sensor Height Above Ground {m}
```

This would change if you had a different wind speed profile exponent or wind speed profile boundary layer thickness at your site.

### 1.6.13 Site:HeightVariation

The **Site:HeightVariation** object is used to specify the local variation in atmospheric properties at the site and should be used only if you require advanced control over the height-dependent variations for wind speed and temperature. The coefficients set by this object are used by EnergyPlus, in conjunction with the **Site:WeatherStation** object (see above), to calculate the local variation in atmospheric properties as a function of height above ground. Outdoor air temperature decreases with height, while wind speed increases with height. The local outdoor air temperature and wind speed are calculated separately for all zones and surfaces, and optionally for outdoor air nodes for which a height has been specified (see **OutdoorAir:Node** object). With the default inputs, wind speed falls significantly at heights lower than the weather station measurement height, and temperature increases slightly. The algorithms for this calculation are in the Engineering Reference. There are necessary correlations between the entries for this object and some entries in the **Building** object, specifically the **Terrain** field.

Table 5. Atmospheric Variables at Two Different Heights Above Ground Level.

Variable	1.5 m	284 m	Absolute Diff	Percent Diff
Air Temperature	15°C	13.15°C	1.85°C	12.3%
Barometric Pressure	101,325 Pa	97,960 Pa	3,365 Pa	3.3%
Wind Speed	2.46 m/s	7.75 m/s	5.29 m/s	215%

Note that using this object overrides the wind speed profile coefficients implied by the *Terrain* field of the **Building** object even if the wind speed profile fields are left blank. The wind speed profile coefficients can be estimated from the table above (see **Site:WeatherStation**) or calculated beforehand using more sophisticated techniques such as CFD modeling of the site terrain.

#### 1.6.13.1 Field: Wind Speed Profile Exponent

The wind speed profile exponent for the terrain surrounding the site. The exponent can be estimated from the table above (see **Site:WeatherStation**) or calculated beforehand using more sophisticated techniques, such as CFD modeling of the site terrain. Note that using this object overrides the wind speed profile coefficients implied by the *Terrain* field of the **Building** object even if this field is left blank. This field can be set to zero to turn off all wind dependence on height.

#### 1.6.13.2 Field: Wind Speed Profile Boundary Layer Thickness

The wind speed profile boundary layer thickness [m] for the terrain surrounding the site. The boundary layer can be estimated from the table above (see **Site:WeatherStation**) or calculated beforehand using more sophisticated techniques, such as CFD modeling of the site terrain. Note that using this object overrides the wind speed profile coefficients implied by the *Terrain* field of the **Building** object even if this field is left blank.

### 1.6.13.3 Field: Air Temperature Gradient Coefficient

The air temperature gradient coefficient [K/m] is a research option that allows the user to control the variation in outdoor air temperature as a function of height above ground. The real physical value is 0.0065 K/m. This field can be set to zero to turn off all temperature dependence on height. Note that the *Air Temperature Sensor Height* in the **Site:WeatherStation** object should also be set to zero in order to force the local outdoor air temperatures to match the weather file outdoor air temperature. This change is required because the **Site:WeatherStation** object assumes an air temperature gradient of 0.0065 K/m. This field can be set to zero to turn off all temperature dependence on height.

```
Site:HeightVariation,  
  0.22, !- Wind Speed Profile Exponent  
  370, !- Wind Speed Profile Boundary Layer Thickness {m}  
  0.0065; !- Air Temperature Gradient Coefficient {deltaC/m}
```

### 1.6.14 Site:GroundTemperature:BuildingSurface

Ground temperatures are used for the ground heat transfer model. There can be only one ground temperature object included, and it is used as the outside surface temperature for all surfaces with Outside Boundary Condition=Ground. The object is options if you have no surfaces with ground contact. The outside surface temperature for individual surfaces can be specified using the OtherSideCoefficients (ref: SurfaceProperty:OtherSideCoefficients) object that allows Toutside to be set with a schedule. This permits using any number of different outside face temperatures in addition to the ground temperature.

Caution: The “undisturbed” ground temperatures calculated by the weather converter should not be used in building losses but are appropriate to be used in the Site:GroundTemperature:Shallow and Site:GroundTemperature:Deep objects. The reasoning (for building losses) is that these values are too extreme for the soil under a conditioned building. For best results, use the Slab or Basement program described in this document to calculate custom monthly average ground temperatures (see the Ground Heat Transfer section). This is especially important for residential applications and very small buildings. If one of these ground temperature preprocessors is not used, for typical commercial buildings in the USA, a reasonable default value is 2C less than the average indoor space temperature.

More information about determining appropriate ground temperatures is given in the Auxiliary Programs document.

#### 1.6.14.1 Field: Month Temperature(s) – 12 fields in all

Each numeric field is the monthly ground temperature (degrees Celsius) used for the indicated month (January=<sup>1</sup> field, February=<sup>2</sup> field, etc.)

An IDF example:

```
Site:GroundTemperature:BuildingSurface,19,20,20,20,20,20,20,20,20,20,20,20;
```

### 1.6.15 Site:GroundTemperature:Shallow

Site:GroundTemperature:Shallow are used by the Surface Ground Heat Exchanger (i.e. object: GroundHeatExchanger:Surface). Only one shallow ground temperature object can be included.

Note that the ground temperatures included in full year weather files may be suitable of being used for the values in these fields – namely, the .5 m depth temperatures that are calculated for “undisturbed” soil of “typical” conditions. However, you may wish to use some other change effect – based on the weather conditions of the building location.

This object may be used for objects requiring “undisturbed” ground temperatures. In these instances, the “name” input field is not required.

#### 1.6.15.1 Field: Month Temperature(s) – 12 fields in all

Each numeric field is the monthly surface ground temperature (degrees Celsius) used for the indicated month (January=<sup>1</sup> field, February=<sup>2</sup> field, etc.)

An IDF example:

```
Site:GroundTemperature:Shallow, 4,4,6,6,10,10,15,15,14,14,8,8;
```

### 1.6.16 Site:GroundTemperature:Deep

Site:GroundTemperature:Deep are used by the Pond Ground Heat Exchanger object (i.e. object: GroundHeatExchanger:Pond). Only one deep ground temperature object can be included.

Note that the ground temperatures included in full year weather files may be suitable of being used for the values in these fields – namely, the 4 m depth temperatures that are calculated for “undisturbed” soil of “typical” conditions. However, you may wish to use some other change effect – based on the weather conditions or special knowledge of the building location.

This object may be used for objects requiring “undisturbed” ground temperatures. In these instances, the “name” input field is not required.

### 1.6.16.1 Field: Month Temperature(s) – 12 fields in all

Each numeric field is the monthly deep ground temperature (degrees Celsius) used for the indicated month (January=1<sup>st</sup> field, February=2<sup>nd</sup> field, etc.)

An IDF example:

```
Site:GroundTemperature:Deep, 16,16,16,16,16,16,16,16,16,16,16,16;
```

### 1.6.17 Site:GroundTemperature:Undisturbed:FiniteDifference

Site:GroundTemperature:Undisturbed:FiniteDifference may be used by all objects requiring "undisturbed" ground temperatures. The object uses a 1D finite difference heat transfer model which uses the weather file to obtain surface boundary conditions. An annual simulation is run on the model during its initialization until the annual ground temperature profile has reached steady periodic behavior. Once steady periodic behavior is reached, the ground temperatures are cached for retrieval during the rest of the simulation.

#### 1.6.17.1 Field: Soil Thermal Conductivity

The thermal conductivity of the soil, in W/m-K.

#### 1.6.17.2 Field: Soil Density

The bulk density of the soil, in kg/m<sup>3</sup>.

#### 1.6.17.3 Field: Soil Specific Heat

The specific heat of dry soil, in J/kg-K.

#### 1.6.17.4 Field: Soil Moisture Content Volume Fraction

A nominal value of soil moisture content to be used when evaluating soil thermal properties.

#### 1.6.17.5 Field: Soil Moisture Content Volume Fraction at Saturation

A nominal value of soil moisture content when the soil is saturated, this is used in evaluating thermal properties of freezing soil.

#### 1.6.17.6 Field: Evapotranspiration Ground Cover Parameter

Numeric field specifies the ground cover effects used in the evapotranspiration model at the ground surface heat balance. The values range from 0 (solid, non-permeable ground surface) to 1.5 (wild growth).

An IDF example:

```
Site:GroundTemperature:Undisturbed:FiniteDifference,
  FDTemps,      !- Name of object
  1.08,         !- Soil Thermal Conductivity {W/m-K}
  962,         !- Soil Density {kg/m3}
  2576,        !- Soil Specific Heat {J/kg-K}
  30,          !- Soil Moisture Content Volume Fraction {percent}
  50,          !- Soil Moisture Content Volume Fraction at Saturation {percent}
  0.408;       !- Evapotranspiration Ground Cover Parameter
```

### 1.6.18 Site:GroundTemperature:Undisturbed:KusudaAchenbach

Site:GroundTemperature:Undisturbed:KusudaAchenbach may be used by all objects requiring "undisturbed" ground temperatures. It provides an undisturbed ground temperature based on the correlation developed by Kusuda T. and P. Achenbach. 1965. The correlation uses three parameters for ground temperature at the surface to define a correlation for undisturbed ground temperatures as a function of depth and time. If one thinks of the ground temperature for a given depth as a sinusoid, the average ground temperature, amplitude (average difference between maximum ground temperature and minimum ground temperature), and the phase shift (day of minimum surface temperature) are all required to define the correlation.

If the parameters are left blank they can be autocalculated by including soil surface temperatures in the input using the Site:GroundTemperature:Shallow object. They can also be calculated by using the CalcSoilSurfTemp preprocessor.

Kusuda, T. and P.R. Achenbach. 1965. 'Earth Temperatures and Thermal Diffusivity at Selected Stations in the United States.' *ASHRAE Transactions*. 71(1): 61-74.

#### 1.6.18.1 Field: Soil Thermal Conductivity

The thermal conductivity of the soil, in W/m-K.

#### 1.6.18.2 Field: Soil Density

The bulk density of the soil, in kg/m<sup>3</sup>.

#### **1.6.18.3 Field: Soil Specific Heat**

The specific heat of dry soil, in J/kg-K.

#### **1.6.18.4 Field: Average Annual Ground Surface Temperature**

This is the average ground surface temperature throughout the entire year, in °C.

#### **1.6.18.5 Field: Average Amplitude of Annual Ground Surface Temperature**

This is the average amplitude of the ground surface temperature, in °C.

#### **1.6.18.6 Field: Phase Shift of Minimum Surface Temperature**

This is day of the year which has the lowest ground surface temperature.

An IDF example:

```
Site:GroundTemperature:Undisturbed:KusudaAchenbach,
KATemps,      !- Name of object
1.08,         !- Soil Thermal Conductivity {W/m-K}
962,          !- Soil Density {kg/m3}
2576,         !- Soil Specific Heat {J/kg-K}
15.5,         !- Average Soil Surface Temperature {C}
12.0,         !- Average Amplitude of Surface Temperature {deltaC}
21;          !- Phase Shift of Minimum Surface Temperature {days}
```

#### **1.6.19 Site:GroundTemperature:Undisturbed:Xing**

Site:GroundTemperature:Undisturbed:Xing may be used by all objects requiring "undisturbed" ground temperatures. It provides an undisturbed ground temperature based on the correlation developed by Xing, 2014. The correlation is a 5 parameter, 2 harmonic model based on the work of Lord Kelvin (Thomson, 1862). The average soil surface temperature and two sets of surface temperature amplitude and phase shift must be provided. Parameters for 4000+ international locations can be found in Xing, 2014.

Thomson, W. 1862. 'On the Reduction of Observations of Underground Temperature, with applications to Professor Forbes' Edinburgh Observations and the continued Calton Hill Series.' Proceedings of the Royal Society of Edinburgh. IV: 342-346.

Xing, L. 2014. Estimations of Undisturbed Ground Temperatures using Numerical and Analytical Modeling. Ph.D. Diss. Oklahoma State University, Stillwater, OK.

#### **1.6.19.1 Field: Soil Thermal Conductivity**

The thermal conductivity of the soil, in W/m-K.

#### **1.6.19.2 Field: Soil Density**

The bulk density of the soil, in kg/m<sup>3</sup>.

#### **1.6.19.3 Field: Soil Specific Heat**

The specific heat of dry soil, in J/kg-K.

#### **1.6.19.4 Field: Average Soil Surface Temperature**

The average annual surface temperature of the soil, in deg C.

#### **1.6.19.5 Field: Soil Surface Temperature Amplitude 1**

First soil surface temperature amplitude parameter, in deg C.

#### **1.6.19.6 Field: Soil Surface Temperature Amplitude 2**

Second soil surface temperature amplitude parameter, in deg C.

#### **1.6.19.7 Field: Phase Shift of Surface Temperature Amplitude 1**

Phase shift of surface temperature amplitude 1, in days.

### 1.6.19.8 Field: Phase Shift of Surface Temperature Amplitude 2

Phase shift of surface temperature amplitude 2, in days.

An IDF example:

```
Site:GroundTemperature:Undisturbed:Xing,  
Chicago-Ohare,    !- Name of object  
1.08,            !- Soil Thermal Conductivity {W/m-K}  
962,             !- Soil Density {kg/m3}  
2576,           !- Soil Specific Heat {J/kg-K}  
11.1,           !- Average Soil Surface Temperature {C}  
13.4,           !- Soil Surface Temperature Amplitude 1 {deltaC}  
0.7,            !- Soil Surface Temperature Amplitude 2 {deltaC}  
25,             !- Phase Shift of Temperature Amplitude 1 {days}  
30;             !- Phase Shift of Temperature Amplitude 2 {days}
```

### 1.6.20 Site:GroundDomain:Slab

This section documents the input object used to simulate ground coupled heat transfer with horizontal building surfaces within EnergyPlus. Horizontal ground surfaces within EnergyPlus interact with the Site:GroundDomain object by utilizing the SurfaceProperty:OtherSideConditionsModel object. By utilizing this object, multiple horizontal surfaces can be coupled to the same Site:GroundDomain object. Each horizontal surface may also have its unique ground domain, however, runtime will be adversely affected.

Generally, there are two scenarios which Site:GroundDomain is equipped to model: in-grade slabs, and on-grade slabs.

Figure 7 In-grade configuration.

The in-grade slab option can be used to simulate situations when the upper slab surface is near the ground surface level. For this situation, slab's upper surface must interact with the zone via an OSCM boundary. Due to this, the FloorConstruction object for the zone floor must include a thin layer of the upper floor material. Horizontal and vertical insulation are modeled by the GroundDomain in this scenario. Horizontal insulation can be modeled as covering the full horizontal surface, or it can be limited to the perimeter regions only. In the latter case, the perimeter insulation width must be specified.

Figure 8 On-grade configuration

The on-grade slab option can be used to simulate situations when the lower slab surface is near the ground surface level. In this situation, the entire floor must be included within the floor construction object. Vertical insulation is modeled by the GroundDomain in this scenario. Horizontal insulation can only be modeled as covering the full horizontal surface.

**1.6.20.1 Field: Name**

Alpha field used as a unique identifier for each ground domain.

**1.6.20.2 Field: Ground Domain Depth**

Numeric field used to determine the depth of the simulation domain, in meters.

**1.6.20.3 Field: Aspect Ratio**

Numeric field used to define the height to width ratio of the slab.

**1.6.20.4 Field: Perimeter Offset**

Numeric field used to determine the distance from the slab perimeter to the domain perimeter, in meters.

**1.6.20.5 Field: Soil Thermal Conductivity**

The thermal conductivity of the soil, in W/m-K.

**1.6.20.6 Field: Soil Density**

The bulk density of the soil, in kg/m<sup>3</sup>.

**1.6.20.7 Field: Soil Specific Heat**

The specific heat of dry soil, in J/kg-K. If moisture is defined in this object, moisture and freezing effects are accounted for by varying the specific heat value.

**1.6.20.8 Field: Soil Moisture Content Volume Fraction**

A nominal value of soil moisture content to be used when evaluating soil thermal properties.

**1.6.20.9 Field: Soil Moisture Content Volume Fraction at Saturation**

A nominal value of soil moisture content when the soil is saturated, this is used in evaluating thermal properties of freezing soil.

**1.6.20.10 Field: Type of Undisturbed Ground Temperature Object**

This is the type of undisturbed ground temperature object that is used to determine the ground temperature.

#### 1.6.20.11 Field: Name of Undisturbed Ground Temperature Object

This is the name of the undisturbed ground temperature object that is used to determine the ground temperature.

#### 1.6.20.12 Field: Evapotranspiration Ground Cover Parameter

Numeric field specifies the ground cover effects used in the evapotranspiration model at the ground surface heat balance. The values range from 0 (solid, non-permeable ground surface) to 1.5 (wild growth).

#### 1.6.20.13 Field: Slab Boundary Condition Model Name

This is the name of the other side boundary condition model used.

#### 1.6.20.14 Field: Slab Location

Alpha field indicates whether the slab is in-grade (top surface level with ground surface) or on-grade (bottoms surface level with ground surface). Options include "ONGRADE" and "INGRADE".

#### 1.6.20.15 Field: Slab Material Name

Name of the material object representing the slab material. Only applicable to in-grade situations.

#### 1.6.20.16 Field: Horizontal Insulation

Alpha field indicates whether horizontal insulation is present. Options include "YES" and "NO". Only applicable to in-grade situations.

#### 1.6.20.17 Field: Horizontal Insulation Material Name

Name of material object representing the horizontal slab insulation. Optional argument only required if horizontal insulation is present.

#### 1.6.20.18 Field: Horizontal Insulation Extents

Alpha field indicates whether the horizontal slab insulation extends to cover the full horizontal area of the slab, or only covers the slab perimeter. Optional argument only required if horizontal insulation is present. Options include "FULL" and "PERIMETER".

#### 1.6.20.19 Field: Perimeter Insulation Width

Numeric field indicating the width of the perimeter insulation measured from the slab edge. Valid range from > 0 to < half of smallest slab width.

#### 1.6.20.20 Field: Vertical Insulation

Alpha field indicates whether vertical insulation is present. Options include "YES" and "NO".

#### 1.6.20.21 Field: Vertical Insulation Name

Name of material object representing the vertical slab insulation. Optional argument only required if vertical insulation is present.

#### 1.6.20.22 Field: Vertical Insulation Depth

Numeric field indicates the depth measured in meters from the ground surface to which the vertical perimeter insulation extends. Valid range from > Slab Thickness to < Domain Depth.

#### 1.6.20.23 Field: Simulation Timestep

Alpha field indicating whether the domain will update temperatures at each zone timestep, or at hourly intervals. Options include "timestep" and "hourly".

An IDF example of an in-grade slab.

## 1.6.21 Site:GroundDomain Outputs

The following output variables are available.

- Zone, Average, Zone Coupled Surface Heat Flux [W/m<sup>2</sup>]
- Zone, Average, Zone Coupled Surface Temperature [C]

### 1.6.21.1 Zone Coupled Surface Heat Flux [W/m<sup>2</sup>]

This is the value of the heat flux provided to the GroundDomain as a boundary condition which is determined by taking the average of all surfaces coupled to the domains OtherSideBoundaryCondition model.

### 1.6.21.2 Zone Coupled Surface Temperature [C]

This is the value of the OthersideConditionModel surface temperature. This is the temperature provided to the ground coupled surfaces as an outside boundary condition.

## 1.6.22 Site:GroundDomain:Basement

This section documents the input object used to simulate ground coupled heat transfer with underground zones within EnergyPlus. Zone surfaces within EnergyPlus interact with the Site:GroundDomain:Basement object by utilizing the SurfaceProperty:OtherSideConditionsModel object. Two separate OSCM are required for the basement vertical and horizontal surfaces. Vertical wall surfaces will interact with the first OSCM while the horizontal floor surface will interact with the second OSCM. Basement floor and wall surfaces are constructed normally by using the BuildingSurface:Detailed object, with the outside boundary condition being the OtherSideConditionsModel for the basement floor or wall. The outside surface of the wall being the interface between the ground domain and the EnergyPlus zone. Horizontal and vertical ground insulation are simulated by the ground domain, and therefore should not be included in the wall and floor construction objects.

```

#### 1.6.22.1 Field: Name

Alpha field used as a unique identifier for each basement domain. Multiple basements domains can be simulated simultaneously, however, each domain must have a unique name. Additionally, despite the ability to simulate multiple domains simultaneously, these domains do not interact with each other and are treated as independent domains with boundary conditions given by the model parameters below.

#### 1.6.22.2 Field: Ground Domain Depth

Numeric field used to determine the depth of the simulation domain, in meters. A value of 10 meters is the default.

#### 1.6.22.3 Field: Aspect Ratio

Numeric field, which is the ratio of basement length to width, used to determine the aspect ratio of the basement. This field along with the total basement floor area, which is taken as the combination of all surfaces connected to the floor OtherSideConditionsModel, are used to determine the size and shape of the basement domain. Aspect ratios and the inverse of aspect ratios should produce identical results. i.e.  $AR = 2$  equals  $AR = 0.5$ . This field has units of meters/meters.

#### 1.6.22.4 Field: Domain Perimeter Offset

Numeric field used to determine the distance from the basement perimeter to the domain perimeter, in meters. A value of 5 is default.

#### **1.6.22.5 Field: Soil Thermal Conductivity**

The thermal conductivity of the soil, in W/m-K.

#### **1.6.22.6 Field: Soil Density**

The bulk density of the soil, in kg/m<sup>3</sup>.

#### **1.6.22.7 Field: Soil Specific Heat**

The specific heat of dry soil, in J/kg-K. If moisture is defined in this object, moisture and freezing effects are accounted for by varying the specific heat value.

#### **1.6.22.8 Field: Soil Moisture Content Volume Fraction**

A nominal value of soil moisture content to be used when evaluating soil thermal properties.

#### **1.6.22.9 Field: Soil Moisture Content Volume Fraction at Saturation**

A nominal value of soil moisture content when the soil is saturated, this is used in evaluating thermal properties of freezing soil.

#### **1.6.22.10 Field: Type of Undisturbed Ground Temperature Object**

This is the type of undisturbed ground temperature object that is used to determine the ground temperature.

#### **1.6.22.11 Field: Name of Undisturbed Ground Temperature Object**

This is the name of the undisturbed ground temperature object that is used to determine the ground temperature.

#### **1.6.22.12 Field: Evapotranspiration Ground Cover Parameter**

Numeric field specifies the ground cover effects used in the evapotranspiration model at the ground surface heat balance. The values range from 0 (solid, non-permeable ground surface) to 1.5 (wild growth). Model can be sensitive to variations in this parameter, especially in dry climates.

#### **1.6.22.13 Field: Basement Floor Boundary Condition Model Name**

This is the name of the other side boundary condition model used for the basement floor surface.

#### **1.6.22.14 Field: Horizontal Insulation**

Alpha field indicates whether horizontal insulation is present. Options include "YES" and "NO".

#### **1.6.22.15 Field: Horizontal Insulation Name**

Name of material object representing the horizontal underfloor basement insulation. Optional argument only required if horizontal insulation is present.

#### **1.6.22.16 Field: Horizontal Insulation Extents**

Alpha field indicates whether the horizontal underfloor insulation extends to cover the full horizontal area of the basement floor, or only covers the basement floor perimeter. Optional argument only required if horizontal insulation is present. Options include "FULL" and "PERIMETER".

#### **1.6.22.17 Field: Perimeter Insulation Width**

Numeric field indicating the width of the perimeter insulation measured from the basement floor edge. Valid range from > 0 to < half of smallest basement floor width.

#### **1.6.22.18 Field: Basement Depth**

Depth of basement floor surface referenced from the ground surface, in meters. This domain should be the distance from the ground surface down to the basement floor surface. In cases where the ground surface is below the main above-ground building level, a separate wall surface should be employed between the basement walls and the main level walls.

#### **1.6.22.19 Field: Basement Wall Boundary Condition Model Name**

Name of the other side condition boundary model used for the basement walls.

#### **1.6.22.20 Field: Vertical Insulation**

Alpha field indicates whether vertical insulation is present. Options include "YES" and "NO".

#### 1.6.22.21 Field: Vertical Insulation Name

Name of material object representing the vertical slab insulation. Optional argument only required if vertical insulation is present.

#### 1.6.22.22 Field: Vertical Insulation Depth

Numeric field indicates the depth measured in meters from the ground surface to which the vertical perimeter insulation extends. Valid range from > 0 to < Basement Depth.

#### 1.6.22.23 Field: Simulation Timestep

Alpha field indicating whether the domain will update temperatures at each zone timestep, or at hourly intervals. Options include "timestep" and "hourly".

#### 1.6.22.24 Mesh Density Parameter

Integer field indicating the density of the finite difference ground domain cells between the basement and the far field boundaries. Default value is 4. Total number of ground domain cells, insulation cells, and ground surface cells are indicated as outputs to the eio file.

Site:GroundDomain:Basement Output Variables

The following output variables are available.

- Wall Interface Heat Flux
- Wall Interface Temperature
- Floor Interface Heat Flux
- Floor Interface Temperature

#### 1.6.22.25 Wall Interface Heat Flux [W/m2]

This is the value of the heat flux provided to ground domain as a boundary condition for the basement walls. Should be equal to the basement wall outside heat flux.

#### 1.6.22.26 Wall Interface Temperature [C]

This is the value of the OthersideConditionModel surface temperature. This is the temperature provided to the basement wall surfaces as an outside boundary condition.

#### 1.6.22.27 Floor Interface Heat Flux [W/m2]

This is the value of the heat flux provided to ground domain as a boundary condition for the basement floor. Should be equal to the basement floor outside heat flux.

#### 1.6.22.28 Floor Interface Temperature [C]

This is the value of the OthersideConditionModel surface temperature. This is the temperature provided to the ground coupled floor surfaces as an outside boundary condition.

### 1.6.23 Site:GroundTemperature:FCfactorMethod

Site:GroundTemperature:FCfactorMethod is used only by the underground walls or slabs-on-grade or underground floors defined with C-factor (Construction:CfactorUndergroundWall) and F-factor (Construction:FfactorGroundFloor) method for code compliance calculations where detailed construction layers are unknown. Only one such ground temperature object can be included. The monthly ground temperatures for this object are close to the monthly outside air temperatures delayed by three months. If user does not input this object in the IDF file, it will be defaulted to the 0.5m set of monthly ground temperatures from the weather file if they are available. Entering these will also overwrite any ground temperatures from the weather file in the F and C factor usage. If neither is available, an error will result.

#### 1.6.23.1 Field: Month Temperature(s) – 12 fields in all

Each numeric field is the monthly ground temperature (degrees Celsius) used for the indicated month (January=1<sup>st</sup> field, February=2<sup>nd</sup> field, etc.)

And, the IDF example:

```
Site:GroundTemperature:FCfactorMethod, 9.5, 3.5, -0.7, -1.7, -0.6, 3.6, 9.3, 14, 18.2, 22.7, 21.2, 16.8;
```

### 1.6.24 Site:GroundReflectance

Ground reflectance values are used to calculate the ground reflected solar amount. This fractional amount (entered monthly) is used in this equation:

$$\text{GroundReflectedSolar} = (\text{BeamSolar} \bullet \text{COS}(\text{SunZenithAngle}) + \text{DiffuseSolar}) \bullet \text{GroundReflectance} \quad (3)$$

Of course, the Ground Reflected Solar is never allowed to be negative. The ground reflectance can be further modified when snow is on the ground by the Snow Ground Reflectance Modifier. To use no ground reflected solar in your simulation, enter 0.0 for each month.

#### 1.6.24.1 Field: Month Average Ground Reflectance(s) – 12 fields in all

Each numeric field is the monthly average reflectivity of the ground used for the indicated month (January=<sup>1</sup>st field, February=<sup>2</sup>nd field, etc.)

And use in an IDF:

```
Site:GroundReflectance,
  0.600,      !January Ground Reflectance
  0.600,      !February Ground Reflectance
  0.400,      !March Ground Reflectance
  0.300,      !April Ground Reflectance
  0.200,      !May Ground Reflectance
  0.200,      !June Ground Reflectance
  0.200,      !July Ground Reflectance
  0.200,      !August Ground Reflectance
  0.200,      !September Ground Reflectance
  0.200,      !October Ground Reflectance
  0.300,      !November Ground Reflectance
  0.400;      !December Ground Reflectance
```

#### 1.6.25 Site:GroundReflectance:SnowModifier

It is generally accepted that snow resident on the ground increases the basic ground reflectance. EnergyPlus allows the user control over the snow ground reflectance for both “normal ground reflected solar” calculations (see above) and snow ground reflected solar modified for daylighting. These are entered under this object and both default to 1 (same as normal ground reflectance – no special case for snow which is a conservative approach).

##### 1.6.25.1 Field: Ground Reflected Solar Modifier

This field is a decimal number which is used to modified the basic monthly ground reflectance when snow is on the ground (from design day input or weather data values).

$$\text{GroundReflectance}_{\text{used}} = \text{GroundReflectance} \bullet \text{Modifier}_{\text{Snow}} \quad (4)$$

The actual Ground Reflectance is limited to [0.0,1.0].

##### 1.6.25.2 Field: Daylighting Ground Reflected Solar Modifier

This field is a decimal number which is used to modified the basic monthly ground reflectance when snow is on the ground (from design day input or weather data values).

$$\text{DaylightingGroundReflectance}_{\text{used}} = \text{GroundReflectance} \bullet \text{Modifier}_{\text{Snow}} \quad (5)$$

The actual Ground Reflectance is limited to [0.0,1.0].

An IDF example:

```
Site:GroundReflectance:SnowModifier,
  1.0;      !- Ground Reflected Solar Modifier
```

Outputs will show both the inputs from the above object as well as monthly values for both Snow Ground Reflectance and Snow Ground Reflectance for Daylighting.

#### 1.6.26 Site:WaterMainsTemperature

The Site:WaterMainsTemperature object is used to calculate water temperatures delivered by underground water main pipes. The mains temperatures are used as default, make-up water temperature inputs for several plant objects, including: **WaterUse:Equipment**, **WaterUse:Connections**, **WaterHeater:Mixed** and **WaterHeater:Stratified**. The mains temperatures are also used in the water systems objects to model the temperature of cold water supplies.

Water mains temperatures are a function of outdoor climate conditions and vary with time of year. A correlation has been formulated to predict water mains temperatures based on two weather inputs:

- average annual outdoor air temperature (dry-bulb)
- maximum difference in monthly average outdoor air temperatures

These values can be easily calculated from annual weather data using a spreadsheet or from the ".stat" file available with the EnergyPlus weather files at

[www.energyplus.gov](http://www.energyplus.gov). Monthly statistics for dry-bulb temperatures are shown with daily averages. The daily averages are averaged to obtain the annual average. The maximum and minimum daily average are subtracted to obtain the maximum difference. For more information on the water mains temperatures correlation, see the *EnergyPlus Engineering Document*.

Alternatively, the Site:WaterMainsTemperature object can read values from a schedule. This is useful for measured data or when water comes from a source other than buried pipes, e.g., a river or lake.

If there is no Site:WaterMainsTemperature object in the input file, a default constant value of 10 C is assumed.

#### 1.6.26.1 Field: Calculation Method

This field selects the calculation method and must have the keyword Schedule or Correlation.

#### 1.6.26.2 Field: Schedule Name

If the calculation method is Schedule, the water mains temperatures are read from the schedule referenced by this field. If the calculation method is Correlation, this field is ignored.

#### 1.6.26.3 Field: Annual Average Outdoor Air Temperature

If the calculation method is Correlation, this field is used in the calculation as the annual average outdoor air temperature (dry-bulb) [C]. If the calculation method is Schedule, this field is ignored.

#### 1.6.26.4 Field: Maximum Difference In Monthly Average Outdoor Air Temperatures

If the calculation method is Correlation, this field is used in the calculation as the maximum difference in monthly average outdoor air temperatures [ $\Delta$ C]. If the calculation method is Schedule, this field is ignored.

```
Site:WaterMainsTemperature,  
  Correlation, !- Calculation Method {SCHEDULE | CORRELATION}  
  , !- Schedule Name  
  9.69, !- Annual Average Outdoor Air Temperature {C}  
  28.1; !- Maximum Difference In Monthly Average Outdoor Air Temperatures  
  !- {deltaC}
```

### 1.6.27 Site:Precipitation

The Site:Precipitation object is used to describe the amount of water precipitation at the building site over the course of the simulation run period. Precipitation includes both rain and the equivalent water content of snow. Precipitation is not yet described well enough in the many building weather data files. So this object can be used to provide the data using Schedule objects that define rates of precipitation in meters per hour.

A set of schedules for site precipitation have been developed for USA weather locations and are provided with EnergyPlus in the data set called PrecipitationSchedulesUSA.idf. The user can develop schedules however they want. The schedules in the data set were developed using EnergyPlus' weather file (EPW) observations and the average monthly precipitation for the closest weather site provided by NOAA. EPW files for the USA that were based on TMY or TMY2 include weather observations for Light/Moderate/Heavy rainfall, however most international locations do not include these observations. The values were modeled by taking the middle of the ranges quoted in the EPW data dictionary. The assumed piecewise function is shown below.

Extra close brace or missing open brace

The values were inserted on hour by hour basis for the month based on the observations. Then each month was rescaled to meet the average precipitation for the month based on the 30-year average (1971-2000) provided by the NOAA/NCDC. Therefore, the flags in the EPW file match the precipitation schedules for the USA. Note that summing the average monthly precipitation values will not give you the average yearly precipitation. The resulting value may be lower or higher than the average yearly value.

Once the typical rainfall pattern and rates are scheduled, the Site:Precipitation object provides a method of shifting the total rainfall up or down for design purposes. Wetter or drier conditions can be modeled by changing the Design Annual Precipitation although the timing of precipitation throughout the year will not be changed.

#### 1.6.27.1 Field: Precipitation Model Type

Choose rainfall modeling options. Only available option is ScheduleAndDesignLevel.

#### 1.6.27.2 Field: Design Level for Total Annual Precipitation

Magnitude of total precipitation for an annual period to be used in the model. Value selected by the user to correspond with the amount of precipitation expected or being assumed for design purposes. The units are in meters. This field works with the following two fields to allow easily shifting the amounts without having to generate new schedules.

#### 1.6.27.3 Field: Precipitation Rate Schedule Name

Name of a schedule defined elsewhere that describes the rate of precipitation. The precipitation rate schedule is analogous to weather file data. However, weather files for building simulation do not currently contain adequate data for such calculations. Therefore, EnergyPlus schedules are used to enter the pattern of precipitation events. The values in this schedule are the average rate of precipitation in meters per hour. The integration of these values over an annual schedule should equal the nominal annual precipitation.

#### 1.6.27.4 Field: Average Total Annual Precipitation

Magnitude of annual precipitation associated with the rate schedule. This value is used to normalize the precipitation.

IDF example:

```
Site:Precipitation,
  ScheduledAndDesignLevel, !- Precipitation Model Type
  0.75, !- Design Level Total Annual Precipitation {m/yr}
  PrecipitationSchd, !- Schedule Name for Precipitation Rates
  0.80771; !- Average Total Annual Precipitation {m/yr}
```

#### 1.6.28 RoofIrrigation

The RoofIrrigation object is used to describe the amount of irrigation on the ecoroof surface over the course of the simulation runperiod. This object is used to provide irrigation data using Schedule objects that define rates of irrigation in meters per hour. These schedules can be one of two types: Schedule, or SmartSchedule.

##### 1.6.28.1 Field: Irrigation Model Type

Choose irrigation modeling options. Available options are **Schedule** and **SmartSchedule**. The **Schedule** type is used to force an irrigation schedule regardless of the current moisture state of the soil. The **SmartSchedule** type allows the precipitation schedule to be overridden if the current moisture state of the soil is greater than 40% saturated.

##### 1.6.28.2 Field: Irrigation Rate Schedule Name

Name of a schedule defined elsewhere that describes the rate of irrigation. The values in this schedule are the average rate of irrigation in meters per hour.

##### 1.6.28.3 Field: Irrigation Maximum Saturation Threshold

Used with the SmartSchedule option in the Irrigation Model Type field to override the default 40% saturation limit for turning off the irrigation: values of 0 to 100 (percent) can be entered with 40% being the default.

IDF example:

```
RoofIrrigation,
  Schedule, !- Irrigation Model Type
  IrrigationSchd; !- Schedule Name for Irrigation Rates
```

#### 1.6.29 Solar and Visible Spectrum Objects

The next two objects enable users to enter solar and visible spectrum which is used to calculate the thermal and visual performance of windows if their glazings are defined with full spectral data. EnergyPlus versions 8.0 and older hard-wired the solar and visible spectrum. The solar spectrum assumes air mass 1.5 terrestrial solar global spectral irradiance values (W/m<sup>2</sup>-micron) on a 37° tilted surface, based on ISO 9845-1 and ASTM E 892; derived from Optics5 data file ISO-9845GlobalNorm.std, 10-14-99. The visible/photopic spectrum is based on CIE 1931 observer; ISO/CIE 10527, CIE Standard Colorimetric Observers; derived from Optics5 data file "CIE 1931 Color Match from E308.txt", which is the same as WINDOW4 file Cie31t.dat.

#### 1.6.30 Site:SolarAndVisibleSpectrum

The SolarAndVisibleSpectrum object is used to specify the solar and visible spectrum data which is used as spectral weighting function to calculate the window performance (transmittance and absorptance) in EnergyPlus. This is a unique object, if it is missing from an IDF file, the default (same as EnergyPlus version 8.0) solar and visible spectrum data will be used.

##### 1.6.30.1 Field: Name

This field specifies the name of the SolarAndVisibleSpectrum object.

##### 1.6.30.2 Field: Spectrum Data Method

This field specifies the method used to enter the spectrum data. Two choices are available: Default and UserDefined. The choice Default will continue to use the hard-wired spectrum data in EnergyPlus (for backward compatibility). The choice UserDefined allows users to specify custom solar and visible spectrum data. The default choice is Default.

##### 1.6.30.3 Field: Solar Spectrum Data Name

This field is required if the Spectrum Data Method is set to UserDefined. This field references a spectrum dataset for solar.

#### 1.6.30.4 Field: Visible Spectrum Data Name

This field is required if the Spectrum Data Method is set to UserDefined. This field references a spectrum dataset for visible.

IDF example:

```
Site:SolarAndVisibleSpectrum,  
  LocalSpectrum,           !- Name  
  UserDefined,             !- Spectrum Data Method: Default, UserDefined  
  SolarSpectrum,          !- Solar Spectrum Data Object Name  
  VisibleSpectrum;        !- Visible Spectrum Data Object
```

### 1.6.31 Site:SpectrumData

The Site:SpectrumData object holds the user defined solar or visible spectrum data. For solar spectrum, up to 107 pairs of (wavelength, spectrum) can be entered. For visible spectrum, up to 81 pairs can be entered.

#### 1.6.31.1 Field: Name

This field specifies the name of the SpectrumData object. The name must be unique across all SpectrumData objects.

#### 1.6.31.2 Field: Spectrum Data Type

This field specifies the type of spectrum data. Choices are Solar and Visible.

#### 1.6.31.3 Field: Wavelength <n>

This field specifies the nth wavelength in micron.

#### 1.6.31.4 Field: Spectrum <n>

This field specifies the nth spectrum corresponding to the nth wavelength.

IDF example:

```
Site:SpectrumData,  
  SolarSpectrum,          !- Name  
  Solar,                  !- Spectrum Data Type  
  0.3,0,                  !- up to 107 pair of (wavelength, spectrum)  
  0.305,3.4,  
  0.31,15.6,  
  0.315,41.1,  
  0.32,71.2,  
  0.325,100.2,  
  0.33,152.4,  
  0.335,155.6,  
  0.34,179.4,  
  0.345,186.7,  
  0.35,212,  
  0.36,240.5,  
  0.37,324,  
  0.38,362.4,  
  ...;
```

### 1.6.32 Climate Group Outputs

Climate related variables appear in two places for EnergyPlus outputs. Certain objects that are invariant throughout a simulation period have lines appear in the eplusout.eio file. For descriptions of this reporting, please see the Output Details and Examples document.

### 1.6.33 Weather Data Related Outputs

Variables related to ambient environment data are available at timestep and higher resolutions. Below is a variable dictionary of these variables and subsequent definitions:

- Zone,Average,Site Outdoor Air Drybulb Temperature [C]
- Zone,Average,Site Outdoor Air Dewpoint Temperature [C]
- Zone,Average,Site Outdoor Air Wetbulb Temperature [C]
- Zone,Average,Site Outdoor Air Humidity Ratio [kgWater/kgAir]

- Zone,Average,Site Outdoor Air Relative Humidity [%]
- Zone,Average,Site Outdoor Air Barometric Pressure [Pa]
- Zone,Average,Site Wind Speed [m/s]
- Zone,Average,Site Wind Direction [deg]
- Zone,Average,Site Sky Temperature [C]
- Zone,Average,Site Horizontal Infrared Radiation Rate per Area [W/m2]
- Zone,Average,Site Diffuse Solar Radiation Rate per Area [W/m2]
- Zone,Average,Site Direct Solar Radiation Rate per Area [W/m2]
- Zone,Sum,Site Precipitation Depth [m]
- Zone,Average,Site Ground Reflected Solar Radiation Rate per Area [W/m2]
- Zone,Average,Site Ground Temperature [C]
- Zone,Average,Site Surface Ground Temperature [C]
- Zone,Average,Site Deep Ground Temperature [C]
- Zone,Average,Site Simple Factor Model Ground Temperature [C]
- Zone,Average,Site Outdoor Air Enthalpy [J/kg]
- Zone,Average,Site Outdoor Air Density [kg/m3]
- Zone,Average,Site Solar Azimuth Angle [deg]
- Zone,Average,Site Solar Altitude Angle [deg]
- Zone,Average,Site Solar Hour Angle [deg]
- Zone,Average,Site Rain Status []
- Zone,Average,Site Snow on Ground Status []
- Zone,Average,Site Exterior Horizontal Sky Illuminance [lux]
- Zone,Average,Site Exterior Horizontal Beam Illuminance [lux]
- Zone,Average,Site Exterior Beam Normal Illuminance [lux]
- Zone,Average,Site Sky Diffuse Solar Radiation Luminous Efficacy [lum/W]
- Zone,Average,Site Beam Solar Radiation Luminous Efficacy [lum/W]
- Zone,Average,Site Daylighting Model Sky Clearness []
- Zone,Average,Site Sky Brightness for Daylighting Calculation []
- Zone,Average,Site Daylight Saving Time Status []
- Zone,Average,Site Day Type Index []
- Zone,Average,Site Mains Water Temperature [C]
- HVAC,Average,Site Precipitation Rate [m/s]
- HVAC,Sum,Site Precipitation Depth [m]
- HVAC,Sum,Water System Roof Irrigation Scheduled Depth[m]
- HVAC,Sum,Water System Roof Irrigation Actual Depth[m]

Note that these data values may be interpolated from "hour" points (ref: Weather Data Hourly Interpolation). Most of the data values represent the "average" over the reporting resolution period.

#### 1.6.33.1 Site Outdoor Air Drybulb Temperature [C]

This is the outdoor dry-bulb temperature in degrees C.

#### 1.6.33.2 Site Outdoor Air Dewpoint Temperature [C]

This is the outdoor dewpoint temperature in degrees C.

#### 1.6.33.3 Site Outdoor Air Wetbulb Temperature [C]

The outdoor wet-bulb temperature is derived (at the timestep) from the values for dry-bulb temperature, humidity ratio and barometric pressure.

#### 1.6.33.4 Site Outdoor Air Humidity Ratio [kgWater/kgAir]

The outdoor humidity ratio is derived (at the timestep) from the dry-bulb temperature, relative humidity and barometric pressure.

#### 1.6.33.5 Site Outdoor Air Relative Humidity [%]

This is the outdoor relative humidity expressed in percent.

#### 1.6.33.6 Site Outdoor Air Barometric Pressure [Pa]

This is the atmospheric/barometric pressure in Pa.

#### 1.6.33.7 Site Wind Speed [m/s]

This is the outdoor wind speed in m/s.

#### 1.6.33.8 Site Wind Direction [deg]

This is the wind direction (N=0, E=90, S=180, W=270).

#### 1.6.33.9 Site Sky Temperature [C]

The sky temperature is derived from horizontal infrared radiation intensity. It is expressed in degrees C. The default calculation is shown below but this value may be modified by the WeatherProperty:SkyTemperature object. Note that Sigma is the Stefan-Boltzmann constant in the following equation:

$$Sky\ Temperature = \left( \frac{Horizontal\ IR}{Sigma} \right)^{\frac{1}{4}} - 273.15_{Conversion\ from\ Kelvin\ to\ Centigrade} \quad (6)$$

#### 1.6.33.10 Site Horizontal Infrared Radiation Rate per Area [W/m2]

The horizontal infrared radiation intensity is expressed in W/m<sup>2</sup> based, if missing from the weather file, on opaque sky cover, sky emissivity, temperature and other factors. The general calculation of Site Horizontal Infrared Radiation Rate per Area is discussed in both the Engineering Reference and the Auxiliary Programs document.

#### 1.6.33.11 Site Diffuse Solar Radiation Rate per Area [W/m2]

Diffuse solar is the amount of solar radiation in W/m<sup>2</sup> received from the sky (excluding the solar disk) on a horizontal surface.

#### 1.6.33.12 Site Direct Solar Radiation Rate per Area [W/m2]

Site Direct Solar Radiation Rate per Area is amount of solar radiation in W/m<sup>2</sup> received within a 5.7° field of view centered on the sun. This is also known as Beam Solar.

#### 1.6.33.13 Site Precipitation Depth [m]

This is the amount of liquid precipitation (m). The source of this field may be the weather file or the Site:Precipitation object. The weather file values are in millimeters, but the report here is in meters. Two separate entities are displayed – from the weather file the key value is “Environment”; from the Site:Precipitation object the key value is Site:Precipitation.

If the weather file does not have a liquid precipitation field but does have the present weather fields, then a heuristic calculation is attempted for both flagging when it is raining and the amount of precipitation. If the weather file does have liquid precipitation fields, then the output (e.g. monthly) can be compared with the weather file stat file.

#### 1.6.33.14 Site Ground Reflected Solar Radiation Rate per Area [W/m2]

The ground reflected solar amount ( $W/m^2$ ) is derived from the Beam Solar, Diffuse Solar, User specified Ground Reflectance (for month) and Solar Altitude Angle:

$$Groundreflectedsolar = (Beamsolar \cdot COS(SolarAltitudeAngle) + Diffusesolar) \cdot Groundreflectance_{month} \quad (7)$$

where if the calculation returns a value  $< 0.0$ , then 0.0 will be reported.

**1.6.33.15 Site Ground Temperature [C]**

The ground temperature is reported in degrees C – this is a user-specified input by month.

**1.6.33.16 Site Surface Ground Temperature [C]**

The ground temperature is reported in degrees C – this is a user-specified input (object: Site:GroundTemperature:Shallow) by month.

**1.6.33.17 Site Deep Ground Temperature [C]**

The ground temperature is reported in degrees C – this is a user-specified input (object: Site:GroundTemperature:Deep) by month.

**1.6.33.18 Site Simple Factor Model Ground Temperature [C]**

The Site Simple Factor Model Ground Temperature is reported in degrees C – this is a user-specified input (object: Site:GroundTemperature:FCfactorMethod) by month or gleaned from the weather file as noted in the description of the object.

**1.6.33.19 Site Outdoor Air Enthalpy [J/kg]**

Outdoor enthalpy is derived at each timestep from the Site Outdoor Air Drybulb Temperature and the Site Outdoor Air Humidity Ratio. It is reported in J/kg.

**1.6.33.20 Site Outdoor Air Density [kg/m3]**

Outdoor air density is derived at each timestep from the Site Outdoor Air Barometric Pressure, the Outdoor Dry-bulb temperature and the Outdoor Humidity Ratio. It is reported in units  $kg/m^3$ .

**1.6.33.21 Site Solar Azimuth Angle [deg]**

The Solar Azimuth Angle ( $\phi$ ) is measured from the North (clockwise) and is expressed in degrees. This is shown more clearly in the following figure.

Figure 9. Solar Position Illustration

#### 1.6.33.22 Site Solar Altitude Angle [deg]

The Solar Altitude Angle ( $b$ ) is the angle of the sun above the horizontal (degrees).

#### 1.6.33.23 Site Solar Hour Angle [deg]

The Solar Hour Angle ( $H$ ) gives the apparent solar time for the current time period (degrees). It is common astronomical practice to express the hour angle in hours, minutes and seconds of time rather than in degrees. You can convert the hour angle displayed from EnergyPlus to time by dividing by 15. (Note that 1 hour is equivalent to 15 degrees;  $360^\circ$  of the Earth's rotation takes place every 24 hours.) The relationship of angles in degrees to time is shown in the following table:

Table 6. Relationship of Angles (degrees) to Time

Unit of Angle	Equivalent time
1 radian	3.819719 hours
1 degree	4 minutes
1 arcmin	4 seconds
1 arcsec	0.066667 seconds

#### 1.6.33.24 Site Rain Status []

This field shows whether or not (1=yes, 0=no) the weather shows "raining". For a Design Day, one can denote rain for the entire day but not timestep by timestep. Weather files may indicate rain for a single time interval. This is an "averaged" field – thus a 1 shown for a time period (e.g. daily reporting) means that it was raining during each timestep of that period.

#### 1.6.33.25 Site Snow on Ground Status []

This field shows whether or not (1=yes, 0=no) the weather shows "snow on the ground". For a Design Day, one can denote snow for the entire day but not timestep by timestep. Weather files may indicate snow (snow depth) for a single time interval. This is an "averaged" field – thus a 1 shown for a time period (e.g. daily reporting) means that there was snow on the ground during each timestep of that period.

#### 1.6.33.26 Site Daylight Saving Time Status []

This field shows when daylight saving time (1=yes, 0=no) is in effect. Though shown as an average variable, this value is only set on a daily basis.

#### 1.6.33.27 Site Day Type Index []

This field shows what "day type" the current day is. Daytypes are (1=Sunday, 2=Monday, etc.) with Holiday=8, SummerDesignDay=9, WinterDesignDay=10, CustomDay1=11, CustomDay2=12. Though shown as an average variable, this value is only set on a daily basis.

#### 1.6.33.28 Site Mains Water Temperature [C]

The value of the Water Mains Temperature is reported in C following the calculation shown in the Water Mains Temperature object.

#### 1.6.33.29 Site Precipitation Rate [m/s]

#### 1.6.33.30 Site Precipitation Depth [m]

The rate and quantity of precipitation at the site. These outputs are only available if a Site Precipitation object is used. Precipitation is measured in meters.

#### 1.6.33.31 Water System Roof Irrigation Scheduled Depth[m]

This is the scheduled amount of irrigation for the green roof (ecorooft) based on the user input. Amount is measured in meters.

#### 1.6.33.32 Water System Roof Irrigation Actual Depth[m]

This is the actual amount of irrigation for the green roof (ecorooft) based on the scheduled user input and moisture state/saturation of the soil. Amount is measured in meters.

### 1.6.34 Outputs for local temperature/wind speed calculations

Local atmospheric properties for outdoor air temperature and wind speed are separately calculated and reported for all zones, surfaces, and outdoor air nodes. The output variables are associated with their respective objects:

- Zone,Average,Zone Outdoor Air Drybulb Temperature [C]
- Zone,Average,Zone Outdoor Air Wetbulb Temperature [C]
- Zone,Average,Zone Outdoor Air Wind Speed [m/s]
- Zone,Average,Surface Ext Outdoor Dry Bulb [C]
- Zone,Average,Surface Ext Outdoor Wet Bulb [C]
- Zone,Average,Surface Ext Wind Speed [m/s]
- HVAC,Average,System Node Temperature [C] (for OUTDOOR AIR NODE object)

#### 1.6.34.1 Zone Outdoor Air Drybulb Temperature [C]

The outdoor air dry-bulb temperature calculated at the height above ground of the zone centroid.

#### 1.6.34.2 Zone Outdoor Air Wetbulb Temperature [C]

The outdoor air wet-bulb temperature calculated at the height above ground of the zone centroid.

#### 1.6.34.3 Zone Outdoor Air Wind Speed [m/s]

The outdoor wind speed calculated at the height above ground of the zone centroid.

#### 1.6.34.4 Surface Ext Outdoor Dry Bulb [C]

The outdoor air dry-bulb temperature calculated at the height above ground of the surface centroid.

#### 1.6.34.5 Surface Ext Outdoor Wet Bulb [C]

The outdoor air wet-bulb temperature calculated at the height above ground of the surface centroid.

#### 1.6.34.6 Surface Ext Wind Speed [m/s]

The outdoor wind speed calculated at the height above ground of the surface centroid.

#### 1.6.34.7 System Node Temperature [C]

When reporting for the **OutdoorAir:Node** object, this is the outdoor air dry-bulb temperature calculated at the height above ground of the node, if height is specified in the input.

## 1.7 Group -- Schedules

This group of objects allows the user to influence scheduling of many items (such as occupancy density, lighting, thermostatic controls, occupancy activity). In addition, schedules are used to control shading element density on the building.

EnergyPlus schedules consist of three pieces: a day description, a week description, and an annual description. An optional element is the schedule type. Each description level builds off the previous sub-level. The day description is simply a name and the values that span the 24 hours in a day to be associated with that name. The week description also has an identifier (name) and twelve additional names corresponding to previously defined day descriptions. There are names for each individual day of the week plus holiday, summer design day, winter design day and two more custom day designations. Finally, the annual schedule contains an identifier and the names and FROM-THROUGH dates of the week schedules associate with this annual schedule. The annual schedule can have several FROM-THROUGH date pairs. One type of schedule reads the values from an external file to facilitate the incorporation of monitored data or factors that change throughout the year.

Schedules are processed by the EnergyPlus Schedule Manager, stored within the Schedule Manager and are accessed through module routines to get the basic values (timestep, hourly, etc). Values are resolved at the Zone Timestep frequency and carry through any HVAC timesteps.

### 1.7.1 Day Type

A brief description of “Day Type” which is used in the SizingPeriod objects, RunPeriodControl:SpecialDays object, the Sizing objects and also used by reference in the Schedule:Week:Daily object (discussed later in this section).

Schedules work on days of the week as well as certain specially designated days. Days of the week are the normal – Sunday, Monday, Tuesday, Wednesday, Thursday, Friday and Saturday. Special day types that can be designated are: Holiday, SummerDesignDay, WinterDesignDay, CustomDay1, CustomDay2. These day types can be used at the user’s convenience to designate special scheduling (e.g. lights, electric equipment, set point temperatures) using these days as reference.

For example, a normal office building may have normal “occupancy” rules during the weekdays but significantly different use on weekend. For this, you would set up rules/schedules based on the weekdays (Monday through Friday, in the US) and different rules/schedules for the weekend (Saturday and Sunday, in the US). However, you could also specially designate SummerDesignDay and WinterDesignDay schedules for sizing calculations. These schedules can be activated by setting the Day Type field in the Design Day object to the appropriate season (**SummerDesignDay** for cooling design calculations; **WinterDesignDay** for heating design calculations).

In a different building, such as a theater/playhouse, the building may only have occupancy during certain weeks of the year and/or certain hours of certain days. If it was every week, you could designate the appropriate values during the “regular” days (Sunday through Saturday). But this would also be an ideal application for the “CustomDay1” and/or “CustomDay2”. Here you would set the significant occupancy, lighting, and other schedules for the custom days and use unoccupied values for the normal weekdays. Then, using a weather file and setting special day periods as appropriate, you will get the “picture” of the building usage during the appropriate periods.

## 1.7.2 ScheduleTypeLimits

Schedule types can be used to validate portions of the other schedules. Hourly day schedules, for example, are validated by range -- minimum/maximum (if entered) -- as well as numeric type (continuous or discrete). Annual schedules, on the other hand, are only validated for range -- as the numeric type validation has already been done.

### 1.7.2.1 Field: Name

This alpha field should contain a unique (within the schedule types) designator. It is referenced wherever Schedule Type Limits Names can be referenced.

### 1.7.2.2 Field: Lower Limit Value

In this field, the lower (minimum) limit value for the schedule type should be entered. If this field is left blank, then the schedule type is not limited to a minimum/maximum value range.

### 1.7.2.3 Field: Upper Limit Value

In this field, the upper (maximum) limit value for the schedule type should be entered. If this field is left blank, then the schedule type is not limited to a minimum/maximum value range.

### 1.7.2.4 Field: Numeric Type

This field designates how the range values are validated. Using **Continuous** in this field allows for all numbers, including fractional amounts, within the range to be valid. Using **Discrete** in this field allows only integer values between the minimum and maximum range values to be valid.

### 1.7.2.5 Field: Unit Type

This field is used to indicate the kind of units that may be associated with the schedule that references the ScheduleTypeLimits object. It is used by IDF Editor to display the appropriate SI and IP units. This field is not used by EnergyPlus. The available options are shown below. If none of these options are appropriate, select **Dimensionless**.

- Dimensionless
- Temperature
- DeltaTemperature
- PrecipitationRate
- Angle
- Convection Coefficient
- Activity Level
- Velocity
- Capacity
- Power
- Availability
- Percent
- Control
- Mode

Several IDF Examples will illustrate the use:

```
ScheduleTypeLimits,Any Number; ! Not limited
ScheduleTypeLimits,Fraction, 0.0 , 1.0 ,CONTINUOUS;
ScheduleTypeLimits,Temperature, -60,200,CONTINUOUS;
ScheduleTypeLimits,Control Type,0,4,DISCRETE;
ScheduleTypeLimits,On/Off,0,1,DISCRETE;
```

### 1.7.3 Day Schedules

The day schedules perform the assignment of pieces of information across a 24 hour day. This can occur in various fashions including a 1-per hour assignment, a user specified interval scheme or a list of values that represent an hour or portion of an hour.

#### 1.7.4 Schedule:Day:Hourly

The Schedule:Day:Hourly contains an hour-by-hour profile for a single simulation day.

##### 1.7.4.1 Field: Name

This field should contain a unique (within all DaySchedules) designation for this schedule. It is referenced by WeekSchedules to define the appropriate schedule values.

##### 1.7.4.2 Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see ScheduleTypeLimits object above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

##### 1.7.4.3 Field: Hour Values (1-24)

These fields contain the hourly values for each of the 24 hours in a day. (Hour field 1 represents clock time 00:00:01 AM to 1:00:00 AM, hour field 2 is 1:00:01 AM to 2:00:00 AM, etc.) The values in these fields will be passed to the simulation as indicated for “scheduled” items.

An IDF example:

```
Schedule:Day:Hourly, Day On Peak, Fraction,
0.,0.,0.,0.,0.,0.,0.,0.,0.,0.,1.,1.,1.,1.,1.,1.,1.,1.,0.,0.,0.,0.,0.,0.;
```

### 1.7.5 Schedule:Day:Interval

The Schedule:Day:Interval introduces a slightly different way of entering the schedule values for a day. Using the intervals, you can shorten the “hourly” input of the “Schedule:Day:Hourly” object to 2 fields. And, more importantly, you can enter an interval that represents only a portion of an hour. Schedule values are “given” to the simulation at the zone timestep, so there is also a possibility of “interpolation” from the entries used in this object to the value used in the simulation.

#### 1.7.5.1 Field: Name

This field should contain a unique (within all DaySchedules) designation for this schedule. It is referenced by WeekSchedules to define the appropriate schedule values.

#### 1.7.5.2 Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see ScheduleTypeLimits object above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

#### 1.7.5.3 Field: Interpolate to Timestep

The value contained in this field directs how to apply values that aren’t coincident with the given timestep (ref: Timestep) intervals. If “Yes” is entered, then any intervals entered here will be interpolated/averaged and that value will be used at the appropriate minute in the hour. If “No” is entered, then the value that occurs on the appropriate minute in the hour will be used as the schedule value.

For example, if “yes” is entered and the interval is every 15 minutes (say a value of 0 for the first 15 minutes, then .5 for the second 15 minutes) AND there is a 10 minute timestep for the simulation: the value at 10 minutes will be 0 and the value at 20 minutes will be .25. For the same input entries but “no” for this field, the value at 10 minutes will be 0 and the value at 20 minutes will be .5.

#### 1.7.5.4 Field-Set: Time and Value (extensible object)

To specify each interval, both an “until” time (which includes the designated time) and the value must be given.

#### 1.7.5.5 Field: Time

The value of each field should represent clock time (standard) in the format "Until: HH:MM". 24 hour clock format (i.e. 1PM is 13:00) is used. Note that Until: 7:00 includes all times up through 07:00 or 7am.

#### 1.7.5.6 Field: Value

This represents the actual value to be passed to the simulation at the appropriate timestep. (Using interpolation value as shown above). Limits on the values are indicated by the Schedule Type Limits Name field of this object.

And an example of use:

```
Schedule:Day:Interval,  
  dd winter rel humidity,  !- Name  
  Percent,                 !- Schedule Type Limits Name  
  No,                      !- Interpolate to Timestep  
  until: 24:00,           !- Time 1  
  74;                     !- Value Until Time 1
```

### 1.7.6 Schedule:Day:List

To facilitate possible matches to externally generated data intervals, this object has been included. In similar fashion to the Schedule:Day:Interval object, this object can also include "sub-hourly" values but must represent a complete day in its list of values.

#### 1.7.6.1 Field: Name

This field should contain a unique (within all day schedules) designation for this schedule. It is referenced by week schedules to define the appropriate schedule values.

#### 1.7.6.2 Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see ScheduleTypeLimits object above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

#### 1.7.6.3 Field: Interpolate to Timestep

The value contained in this field directs how to apply values that aren't coincident with the given timestep (ref: Timestep) intervals. If "Yes" is entered, then any intervals entered here will be interpolated/averaged and that value will be used at the appropriate minute in the hour. If "No" is entered, then the value that occurs on the appropriate minute in the hour will be used as the schedule value.

For example, if "yes" is entered and the minutes per item is 15 minutes (say a value of 0 for the first 15 minutes, then .5 for the second 15 minutes) AND there is a 10 minute timestep for the simulation: the value at 10 minutes will be 0 and the value at 20 minutes will be .25. For the same input entries but "no" for this field, the value at 10 minutes will be 0 and the value at 20 minutes will be .5.

#### 1.7.6.4 Field: Minutes Per Item

This field allows the "list" interval to be specified in the number of minutes for each item. The value here must be  $\leq 60$  and evenly divisible into 60 (same as the timestep limits).

#### 1.7.6.5 Field Value 1 (same definition for each value – up to 1440 (24\*60) allowed)

This is the value to be used for the specified number of minutes.

For example:

```
Schedule:Day:List,  
  Myschedule,  ! name  
  Fraction,    ! Schedule type  
  No,         ! Interpolate value  
  30,         ! Minutes per item  
  0.0,       ! from 00:01 to 00:30  
  0.5,       ! from 00:31 to 01:00  
  <snipped>
```

### 1.7.7 Week Schedule(s)

The week schedule object(s) perform the task of assigning the day schedule to day types in the simulation. The basic week schedule is shown next.

### 1.7.8 Schedule:Week:Daily

#### 1.7.8.1 Field: Name

This field should contain a unique (within all WeekSchedules) designation for this schedule. It is referenced by Schedules to define the appropriate schedule

values.

### 1.7.8.2 Field: Schedule Day Name Fields (12 day types – Sunday, Monday, ... )

These fields contain day schedule names for the appropriate day types. Days of the week (or special days as described earlier) will then use the indicated hourly profile as the actual schedule value.

An IDF example:

```
Schedule:Week:Daily, Week on Peak,  
    Day On Peak,Day On Peak,Day On Peak,  
    Day On Peak,Day On Peak,Day On Peak,  
    Day On Peak,Day On Peak,Day On Peak,  
    Day On Peak,Day On Peak,Day On Peak;
```

### 1.7.9 Schedule:Week:Compact

Further flexibility can be realized by using the Schedule:Week:Compact object. In this the fields, after the name is given, a “for” field is given for the days to be assigned and then a dayschedule name is used.

#### 1.7.9.1 Field:Name

This field should contain a unique (within all WeekSchedules) designation for this schedule. It is referenced by Schedules to define the appropriate schedule values.

#### 1.7.9.2 Field-Set – DayType List#, Schedule:Day Name #

Each assignment is made in a pair-wise fashion. First the “days” assignment and then the dayschedule name to be assigned. The entire set of day types must be assigned or an error will result.

#### 1.7.9.3 Field: DayType List #

This field can optionally contain the prefix “For” for clarity. Multiple choices may then be combined on the line. Choices are: Weekdays, Weekends, Holidays, AllDays, SummerDesignDay, WinterDesignDay, Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, CustomDay1, CustomDay2. In fields after the first “for”, AllOtherDays may also be used. Note that the colon (:) after the For is optional but is suggested for readability.

#### 1.7.9.4 Field: Schedule:Day Name #

This field contains the name of the day schedule (any of the Schedule:Day object names) that is to be applied for the days referenced in the prior field.

Some IDF examples:

```
Schedule:Week:Compact, Week on Peak,  
    For: AllDays,  
    Day On Peak;  
Schedule:Week:Compact, WeekDays on Peak,  
    WeekDays,  
    Day On Peak,  
    AllOtherDays  
    Day Off Peak;
```

### 1.7.10 Schedule:Year

The yearly schedule is used to cover the entire year using references to week schedules (which in turn reference day schedules). If the entered schedule does not cover the entire year, a fatal error will result.

#### 1.7.10.1 Field: Name

This field should contain a unique (between Schedule:Year, Schedule:Compact, and Schedule:File) designation for the schedule. It is referenced by various “scheduled” items (e.g. Lights, People, Infiltration) to define the appropriate schedule values.

#### 1.7.10.2 Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see ScheduleTypeLimits object above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

#### 1.7.10.3 Field Set (WeekSchedule, Start Month and Day, End Month and Day)

Each of the designated fields is used to fully define the schedule values for the indicated time period). Up to 53 sets can be used. An error will be noted and EnergyPlus will be terminated if an incomplete set is entered. Missing time periods will also be noted as warning errors; for these time periods a zero (0.0) value

will be returned when a schedule value is requested. Each of the sets has the following 5 fields:

#### 1.7.10.4 Field: Schedule Week Name #

This field contains the appropriate WeekSchedule name for the designated time period.

#### 1.7.10.5 Field: Start Month #

This numeric field is the starting month for the schedule time period.

#### 1.7.10.6 Field: Start Day #

This numeric field is the starting day for the schedule time period.

#### 1.7.10.7 Field: End Month #

This numeric field is the ending month for the schedule time period.

#### 1.7.10.8 Field: End Day #

This numeric field is the ending day for the schedule time period.

Note that there are many possible periods to be described. An IDF example with a single period:

```
Schedule:Year, On Peak, Fraction,  
    Week On Peak, 1,1, 12,31;
```

And a multiple period illustration:

```
Schedule:Year, CoolingCoilAvailSched, Fraction,  
    FanAndCoilAllOffWeekSched, 1,1, 3,31,  
    FanAndCoilSummerWeekSched, 4,1, 9,30,  
    FanAndCoilAllOffWeekSched, 10,1, 12,31;
```

The following definition will generate an error (if any scheduled items are used in the simulation):

```
Schedule:Year,MySchedule,Fraction,4,1,9,30;
```

### 1.7.11 Schedule:Compact

For flexibility, a schedule can be entered in “one fell swoop”. Using the Schedule:Compact object, all the features of the schedule components are accessed in a single command. Like the “regular” schedule object, each schedule:compact entry must cover all the days for a year. Additionally, the validations for DaySchedule (i.e. must have values for all 24 hours) and WeekSchedule (i.e. must have values for all day types) will apply. Schedule values are “given” to the simulation at the zone timestep, so there is also a possibility of “interpolation” from the entries used in this object to the value used in the simulation.

This object is an unusual object for description. For the data the number of fields and position are not set, they cannot really be described in the usual Field # manner. Thus, the following description will list the fields and order in which they must be used in the object. The name and schedule type are the exceptions:

#### 1.7.11.1 Field: Name

This field should contain a unique (between Schedule:Year, Schedule:Compact, and Schedule:File) designation for the schedule. It is referenced by various “scheduled” items (e.g. Lights, People, Infiltration) to define the appropriate schedule values.

#### 1.7.11.2 Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see ScheduleTypeLimits object above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

#### 1.7.11.3 Field-Set (Through, For, Interpolate, Until, Value)

Each compact schedule must contain the elements Through (date), For (days), Interpolate (optional), Until (time of day) and Value. In general, each of the “titled” fields must include the “title”. Note that the colon (:) after these elements (Through, For, Until) is optional but is suggested for readability.

#### 1.7.11.4 Field: Through

This field starts with “Through:” and contains the ending date for the schedule period (may be more than one). Refer to Table 3. Date Field Interpretation for information on date entry – note that only Month-Day combinations are allowed for this field. Each “through” field generates a new WeekSchedule named “Schedule Name”\_wk\_# where # is the sequential number for this compact schedule.

#### 1.7.11.5 Field: For

This field starts with "For:" and contains the applicable days (reference the compact week schedule object above for complete description) for the 24 hour period that must be described. Each "for" field generates a new DaySchedule named "Schedule Name" \_dy\_# where # is the sequential number for this compact schedule.

#### 1.7.11.6 Field: Interpolate (optional)

This field, if used, starts with "Interpolate:" and contains the word "Yes" or "No". If this field is not used, it should not be blank – rather just have the following field appear in this slot. The definition of "Interpolate" in this context is shown in the interval day schedule above.

#### 1.7.11.7 Field: Until

This field contains the ending time (again, reference the interval day schedule discussion above) for the current days and day schedule being defined.

#### 1.7.11.8 Field: Value

Finally, the value field is the schedule value for the specified time interval.

And, some IDF examples:

```
Schedule:Compact,  
  POFF,      !- Name  
  Fraction,  !- Schedule Type Limits Name  
  Through: 4/30,  
  For: AllDays,  
  Until: 24:00, 1.0,  
  Through: 12/31,  
  For: Weekdays,  
    Until: 7:00, .1,  
    Until: 17:00, 1.0,  
    Until: 24:00, .1,  
  For: Weekends Holidays,  
    Until: 24:00, .1,  
  For: AllOtherDays,  
    Until: 24:00, .1;
```

```
! Schedule Continuous
```

```
Schedule:Compact,  
  Continuous,  
  on/off,  
  Through: 12/31,  
  For: AllDays,  
  Until: 24:00, 1.0;
```

```
! Schedule Daytime Ventilation
```

```
Schedule:Compact,  
  Daytime Ventilation,  
  Fraction,  
  Through: 12/31,  
  For: Weekdays SummerDesignDay,  
  Until: 08:00, 0.0,  
  Until: 18:00, 1.0,  
  Until: 24:00, 0.0,  
  For: Weekends WinterDesignDay,  
  Until: 10:00, 0.0,  
  Until: 16:00, 1.0,  
  Until: 24:00, 0.0,  
  For: Holidays AllOtherDays,  
  Until: 24:00, 0.0;
```

### 1.7.12 Schedule:Constant

The constant schedule is used to assign a constant hourly value. This schedule is created when a fixed hourly value is desired to represent a period of interest (e.g., always on operation mode for supply air fan).

#### 1.7.12.1 Field: Name

This field should contain a unique name designation for this schedule. It is referenced by Schedules to define the appropriate schedule value.

#### 1.7.12.2 Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see ScheduleTypeLimits object above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

### 1.7.12.3 Field: Hourly Value

This field contains a constant real value. A fixed value is assigned as an hourly value.

An IDF example:

```
Schedule:Constant,  
  AlwaysOn,           !- Name  
  On/Off,             !- Schedule Type Limits Name  
  1.0;                !- Hourly Value
```

```
ScheduleTypeLimits,  
  On/Off,             !- Name  
  0,                  !- Lower Limit Value  
  1,                  !- Upper Limit Value  
  DISCRETE,          !- Numeric Type  
  Availability;       !- Unit Type
```

### 1.7.13 Schedule:File

At times, data is available from a building being monitored or for factors that change throughout the year. The Schedule:File object allows this type of data to be used in EnergyPlus as a schedule. Schedule:File can also be used to read in hourly or sub-hourly schedules computed by other software or developed in a spreadsheet or other utility.

The format for the data file referenced is a text file with values separated by commas (or other optional delimiters) with one line per hour. The file may contain header lines that are skipped. The file should contain values for an entire year (8760 or 8784 hours of data) or a warning message will be issued. Multiple schedules may be created using a single external data file or multiple external data files may be used. The first row of data must be for January 1, hour 1 (or timestep 1 for subhourly files).

Schedule:File may be used along with the FuelFactors object and TDV files in the DataSets directory to compute Time Dependent Valuation based source energy as used by the California Energy Commission's Title 24 Energy Code. See Fuel Factor for more discussion on Time Dependent Valuation.

Two optional fields: **Interpolate to Timestep** and **Minutes per Item** allow for the input of sub-hourly schedules (similar to the Schedule:Day:List object).

#### 1.7.13.1 Field: Name

This field should contain a unique (between Schedule:Year, Schedule:Compact, and Schedule:File) designation for the schedule. It is referenced by various "scheduled" items (e.g. Lights, People, Infiltration, FuelFactors) to define the appropriate schedule values.

#### 1.7.13.2 Field: Schedule Type Limits Name

This field contains a reference to the Schedule Type Limits object. If found in a list of Schedule Type Limits (see ScheduleTypeLimits object above), then the restrictions from the referenced object will be used to validate the hourly field values (below).

#### 1.7.13.3 Field: File Name

This field contains the name of the file that contains the data for the schedule. The field should include a full path with file name, for best results. The field must be <= 100 characters. The file name must not include commas or an exclamation point. A relative path or a simple file name should work with version 7.0 or later when using EP-Launch even though EP-Launch uses temporary directories as part of the execution of EnergyPlus. If using RunEPlus.bat to run EnergyPlus from the command line, a relative path or a simple file name may work if RunEPlus.bat is run from the folder that contains EnergyPlus.exe.

#### 1.7.13.4 Field: Column Number

The column that contains the value to be used in the schedule. The first column is column one. If no data for a row appears for a referenced column the value of zero is used for the schedule value for that hour.

#### 1.7.13.5 Field: Rows to Skip at Top

Many times the data in a file contains rows (lines) that are describing the files or contain the names of each column. These rows need to be skipped and the number of skipped rows should be entered for this field. The next row after the skipped rows must contain data for January 1, hour 1.

#### 1.7.13.6 Field: Number of Hours of Data

The value entered in this field should be either 8760 or 8784 as the number of hours of data. 8760 does not include the extra 24 hours for a leap year (if needed). 8784 will include the possibility of leap year data which can be processed according to leap year indicators in the weather file or specified elsewhere. Note if the simulation does not have a leap year specified but the schedule file contains 8784 hours of data, the first 8760 hours of data will be used. The schedule manager will not know to skip the 24 hours representing February 29.

#### 1.7.13.7 Field: Column Separator

This field specifies the character used to separate columns of data if the file has more than one column. The choices are: Comma, Tab, Fixed (spaces fill each column to a fixed width), or Semicolon. The default is Comma.

### 1.7.13.8 Field: Interpolate to Timestep

The value contained in this field directs how to apply values that aren't coincident with the given timestep (ref: TimeStep object) intervals. If "Yes" is entered, then any intervals entered here will be interpolated/averaged and that value will be used at the appropriate minute in the hour. If "No" is entered, then the value that occurs on the appropriate minute in the hour will be used as the schedule value.

For example, if "yes" is entered and the minutes per item is 15 minutes (say a value of 0 for the first 15 minutes, then .5 for the second 15 minutes) AND there is a 10 minute timestep for the simulation: the value at 10 minutes will be 0 and the value at 20 minutes will be .25. For the same input entries but "no" for this field, the value at 10 minutes will be 0 and the value at 20 minutes will be .5.

### 1.7.13.9 Field: Minutes Per Item

This field represents the number of minutes for each item – in this case each line of the file. The value here must be <= 60 and evenly divisible into 60 (same as the timestep limits).

Here is an IDF example:

```
Schedule:File,
  electDVfromCZ01res,    !- Name
  Any Number,           !- ScheduleType
  TDV_kBtu_CTZ01.csv,   !- Name of File
  2,                    !- Column Number
  4,                    !- Rows to Skip at Top
  8760,                 !- Number of Hours of Data
  Comma,                !- Column Separator
```

or with a relational path:

```
Schedule:File,
  electDVfromCZ01res,    !- Name
  Any Number,           !- ScheduleType
  DataSets\TDV\TDV_kBtu_CTZ01.csv, !- Name of File
  2,                    !- Column Number
  4;                    !- Rows to Skip at Top
```

A sub-hourly indication. Note that this is identical to an hourly file because there are 60 minutes per item – the number of hours defaults to 8760 and the column separator defaults to a comma. If the number of minutes per item had been, say, 15, then the file would need to contain 8760\*4 or 35,040 rows for this item.

```
Schedule:File,
  electDVfromCZ06com,    !- Name
  Any Number,           !- Schedule Type Limits Name
  DataSets\TDV\TDV_2008_kBtu_CTZ06.csv, !- File Name
  1,                    !- Column Number
  4,                    !- Rows to Skip at Top
  ,                     !- Number of Hours of Data
  ,                     !- Column Separator
  ,                     !- Interpolate to Timestep
  60;                   !- Minutes per Item
```

## 1.7.14 Schedule Outputs

An optional report can be used to gain the values described in the previous Schedule objects. This is a condensed reporting that illustrates the full range of schedule values – in the style of input: DaySchedule, WeekSchedule, Annual Schedule.

! will give them on hourly increments (day schedule resolution)

```
Output:Reports, Schedules, Hourly;
```

! will give them at the timestep of the simulation

```
Output:Reports, Schedules, Timestep;
```

This report is placed on the eplusout.eio file. Details of this reporting are shown in the Output Details and Examples document.

### 1.7.14.1 Schedule Value Output

```
Zone,Average,Schedule Value []
```

### 1.7.14.2 Schedule Value

This is the schedule value (as given to whatever entity that uses it). It has no units in this context because values may be many different units (i.e. temperatures,

fractions, watts). For best results, you may want to apply the schedule name when you use this output variable to avoid output proliferation. For example, the following reporting should yield the values shown above, depending on day of week and day type:

```
Output:Variable,People_Shopping_Sch,Schedule Value,hourly;  
Output:Variable,Activity_Shopping_Sch,Schedule Value,hourly;
```

## 1.8 Group – Surface Construction Elements

This group of objects describes the physical properties and configuration for the building envelope and interior elements. That is, the walls, roofs, floors, windows, doors for the building.

### 1.8.1 Specifying the Building Envelope

Building element constructions in EnergyPlus are built from the basic thermal and other material property parameters in physical constructions. Materials are specified by types and named. Constructions are defined by the composition of materials. Finally, surfaces are specified for the building with geometric coordinates as well as referenced constructions.

### 1.8.2 Material and Material Properties

There are several material “types” which may be used to describe layers within opaque construction elements. The choice of which of these types to use is left up to the user. However, some guidance as to which material type to use is appropriate before describing each in detail. The opaque types are:

- Material
- Material:NoMass
- Material:AirGap
- Material:RoofVegetation
- Material:InfraredTransparent

Material is the “preferred” type of material. This requires knowledge of many of the thermal properties of the material, but it allows EnergyPlus to take into account the thermal mass of the material and thus allows the evaluation of transient conduction effects. Material:NoMass is similar in nature but only requires the thermal resistance (R-value) rather than the thickness, thermal conductivity, density, and specific heat. Note that using a simple R-value only material forces EnergyPlus to assume steady state heat conduction through this material layer. Finally, Material:AirGap should only be used for an air gap between other layers in a construction. This type assumes that air is sufficiently lightweight to require only an R-value. In addition, since it is not exposed to any external environment, surface properties such as absorptance are not necessary. Material:RoofVegetation is used to help model “green roofs”. Material:InfraredTransparent is used similarly to the NoMass materials. Each of these materials is described in more detail below.

There are several material additions that can be made to the basic material properties. These additional material types are:

- MaterialProperty:MoisturePenetrationDepth:Settings
- MaterialProperty:HeatAndMoistureTransfer:SorptionIsotherm
- MaterialProperty:HeatAndMoistureTransfer:Diffusion
- MaterialProperty:HeatAndMoistureTransfer:Settings
- MaterialProperty:HeatAndMoistureTransfer:Redistribution
- MaterialProperty:HeatAndMoistureTransfer:Suction
- MaterialProperty:HeatAndMoistureTransfer:ThermalConductivity
- MaterialProperty:PhaseChange

These material property objects are used in conjunction with the basic material specification and reference back to the name of the basic material type. Without the basic material type specified the program, will give a severe error and terminate. For example, specifying the moisture materials and changing the HeatBalanceAlgorithm to a moisture simulation will allow the moisture simulation to take place.

### 1.8.3 Material

This definition should be used when the four main thermal properties (thickness, conductivity, density, and specific heat) of the material are known. This syntax is used to describe opaque construction elements only.

When a Material is used for the Construction of a building surface, care should be taken to not attempt to model assemblies that were not included in the intended scope of applicability for the underlying heat transfer models. The building surface models are for normal applications to building energy efficiency where the main focus is on assemblies with some thermal resistance. Extremely thin and/or highly conductive material layers should be neglected from the Construction rather than included because they will not contribute to the assembly’s overall thermal resistance or heat capacity. For some cases, thin and/or

highly conductive materials are a serious problem for the heat transfer modeling and the values for thickness, conductivity, density and specific heat are checked for appropriateness. This check calculates the Material's thermal diffusivity from the inputs for conductivity, density, and specific heat and compares it to a maximum threshold of  $1.E-5$  ( $m^2/s$ ). If the diffusivity is above this threshold, then the program checks if the layer is sufficiently thick and may issue a warning if it is too thin and highly conductive.

The absorptance values in this object impart surface properties to the construction and should be applied to the thermally significant inner and outer layers in the overall assembly. Attempting to trick the program by modeling thin "paint" layers to apply surface properties is not a good idea; the models were not intended to support such strategies.

#### 1.8.3.1 Field: Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data (ref: Construction object).

#### 1.8.3.2 Field: Roughness

This alpha field defines the relative roughness of a particular material layer. This parameter only influences the convection coefficients, more specifically the exterior convection coefficient. A special keyword is expected in this field with the options being "VeryRough", "Rough", "MediumRough", "MediumSmooth", "Smooth", and "VerySmooth" in order of roughest to smoothest options.

#### 1.8.3.3 Field: Thickness

This field characterizes the thickness of the material layer in meters. This should be the dimension of the layer in the direction perpendicular to the main path of heat conduction. This value must be a positive. **Modeling layers thinner (less) than 0.003 m is not recommended; rather, add those properties to one of the adjacent layers.**

#### 1.8.3.4 Field: Conductivity

This field is used to enter the thermal conductivity of the material layer. Units for this parameter are  $W/(m-K)$ . Thermal conductivity must be greater than zero. **Modeling layers with conductivity higher than 5.0  $W/(m-K)$  is not recommended; however, this may be appropriate for non-surfaces such as pipes and TDDs (ref. DaylightingDevice:Tubular object).**

#### 1.8.3.5 Field: Density

This field is used to enter the density of the material layer in units of  $kg/m^3$ . Density must be a positive quantity. **In some cases textbooks and references may use  $g/m^3$ : be careful to not confuse units.**

#### 1.8.3.6 Field: Specific Heat

This field represents the specific heat of the material layer in units of  $J/(kg-K)$ . Note that these units are most likely different than those reported in textbooks and references which tend to use  $kJ/(kg-K)$  or  $J/(g-K)$ . They were chosen for internal consistency within EnergyPlus. **Only values of specific heat of 100 or larger are allowed. Typical ranges are from 800 to 2000  $J/(kg-K)$ .**

#### 1.8.3.7 Field: Thermal Absorptance

The thermal absorptance field in the Material input syntax represents the fraction of incident long wavelength radiation that is absorbed by the material. This parameter is used when calculating the long wavelength radiant exchange between various surfaces and affects the surface heat balances (both inside and outside as appropriate). For long wavelength radiant exchange, thermal emissivity and thermal emittance are equal to thermal absorptance. Values for this field must be between 0.0 and 1.0 (with 1.0 representing "black body" conditions). The default value for this field is 0.9.

#### 1.8.3.8 Field: Solar Absorptance

The solar absorptance field in the Material input syntax represents the fraction of incident solar radiation that is absorbed by the material. Solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the amount of incident solar radiation absorbed by various surfaces and affects the surface heat balances (both inside and outside as appropriate). If solar reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials). Values for this field must be between 0.0 and 1.0. The default value for this field is 0.7.

#### 1.8.3.9 Field: Visible Absorptance

The visible absorptance field in the Material input syntax represents the fraction of incident visible wavelength radiation that is absorbed by the material. Visible wavelength radiation is slightly different than solar radiation in that the visible band of wavelengths is much more narrow while solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the amount of incident visible radiation absorbed by various surfaces and affects the surface heat balances (both inside and outside as appropriate) as well as the daylighting calculations. If visible reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials). Values for this field must be between 0.0 and 1.0. The default value for this field is 0.7.

An IDF example:

```
Material,A2 - 4 IN DENSE FACE BRICK, ! Material Name
Rough, ! Roughness
0.1014984 , ! Thickness {m}
1.245296 , ! Conductivity {W/M*K}
2082.400 , ! Density {Kg/M**3}
920.4800 , ! Specific Heat {J/Kg*K}
0.9000000 , ! Thermal Absorptance
0.9300000 , ! Solar Absorptance
0.9300000 ; ! Visible Absorptance
```

## 1.8.4 Material:NoMass

Use this definition when only the thermal resistance (R value) of the material is known. This object is used to describe opaque construction elements.

### 1.8.4.1 Field: Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data (ref: Construction object).

### 1.8.4.2 Field: Roughness

This alpha field defines the relative roughness of a particular material layer. This parameter only influences the convection coefficients, more specifically the exterior convection coefficient. A keyword is expected in this field with the options being “**VeryRough**”, “**Rough**”, “**MediumRough**”, “**MediumSmooth**”, “**Smooth**”, and “**VerySmooth**” in order of roughest to smoothest options.

### 1.8.4.3 Field: Thermal Resistance

This field is used to enter the thermal resistance (R-value) of the material layer. Units for this parameter are (m<sup>2</sup>-K)/W. Thermal resistance must be greater than zero. Note that most R-values in the USA are calculated in Inch-Pound units and must be converted to the SI equivalent.

### 1.8.4.4 Field: Thermal Absorptance

The thermal absorptance field in the Material input syntax represents the fraction of incident long wavelength radiation that is absorbed by the material. This parameter is used when calculating the long wavelength radiant exchange between various surfaces and affects the surface heat balances (both inside and outside as appropriate). For long wavelength radiant exchange, thermal emissivity and thermal emittance are equal to thermal absorptance. Values for this field must be between 0.0 and 1.0 (with 1.0 representing “black body” conditions). The default value for this field is 0.9.

### 1.8.4.5 Field: Solar Absorptance

The solar absorptance field in the Material input syntax represents the fraction of incident solar radiation that is absorbed by the material. Solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the amount of incident solar radiation absorbed by various surfaces and affects the surface heat balances (both inside and outside as appropriate). If solar reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials). Values for this field must be between 0.0 and 1.0. The default value for this field is 0.7.

### 1.8.4.6 Field: Visible Absorptance

The visible absorptance field in the Material input syntax represents the fraction of incident visible wavelength radiation that is absorbed by the material. Visible wavelength radiation is slightly different than solar radiation in that the visible band of wavelengths is much more narrow while solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the amount of incident visible radiation absorbed by various surfaces and affects the surface heat balances (both inside and outside as appropriate) as well as the daylighting calculations. If visible reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials). Values for this field must be between 0.0 and 1.0. The default value for this field is 0.7.

An IDF example:

```
Material:NoMass,R13LAYER, ! Material Name
Rough, ! Roughness
2.290965 , ! Resistance {M**2K/W}
0.9000000 , ! Thermal Absorptance
0.7500000 , ! Solar Absorptance
0.7500000 ; ! Visible Absorptance
```

## 1.8.5 Material:InfraredTransparent

An Infrared Transparent surface is similar to a resistance-only surface. The idd object for this type of surface is shown below. The surface will actually participate in the transfer of visible and solar radiation by doing a wavelength transformation and making all short wave length radiation that is incident on the surface into long wave length radiation and having it participate in the long wavelength radiant exchange. **Note the ConvectionCoefficient instructions that follow the Infrared Transparent construction object below.**

### 1.8.5.1 Field: Name

This field contains the unique name (across all Material objects) for the Infrared Transparent material.

An Infrared Transparent surface should not participate in a convective/conductive exchange between the zones it separates. In order to minimize this effect, the ConvectionCoefficients object must be used for the surfaces referencing the Infrared Transparent (IRT) construction.

An example idf object specification for use with the IRT surface is shown below. Note that surfaces are not described in this example

```
Material:InfraredTransparent,

  value,        !- Convection Value Type 2
  0.1;         !- Convection value 2 {W/m2-K}
```

## 1.8.6 Material:AirGap

This material is used to describe the air gap in an opaque construction element. Glass elements use a different property (WindowGas) to describe the air between two glass layers.

### 1.8.6.1 Field: Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data (ref: Construction object).

### 1.8.6.2 Field: Thermal Resistance

This field is used to enter the thermal resistance (R-value) of the material layer. Units for this parameter are (m<sup>2</sup>-K)/W. Thermal resistance must be greater than zero. Note that most R-values in the USA are calculated in Inch-Pound units and must be converted to the SI equivalent.

An IDF example:

```
Material:AirGap,B1 - AIRSPACE RESISTANCE, ! Material Name
```

### 1.8.7 MaterialProperty:MoisturePenetrationDepth:Settings

This material is used to describe the five moisture material properties that are used in the EMPD (Effective Moisture Penetration Depth) heat balance solution algorithm (known there as MoisturePenetrationDepthConductionTransferFunction). The EMPD algorithm is a simplified, lumped moisture model that simulates moisture storage and release from interior surfaces. The model uses "actual" convective mass transfer coefficients that are determined by existing heat and mass transfer relationships, e.g. the Lewis relation. An effective moisture penetration depth may be determined from either experimental or detailed simulation data by using actual surface areas and moisture sorption isotherms.

This moisture model will be used when the appropriate EMPD moisture materials are specified and the Solution Algorithm parameter is set to EMPD.

#### 1.8.7.1 Field: Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data (ref: Construction object).

#### 1.8.7.2 Field: Moisture Penetration Depth

This field is used to enter the effective moisture penetration depth of the material layer. Units for this parameter are (m).

#### 1.8.7.3 Field: Constants to Define Moisture Equilibrium Equation

The next four fields, coefficients "a", "b", "c", and "d", help define the sorption isotherm curve used for building materials under equilibrium conditions. They are used to define the relationship between the material's moisture content and the surface air relative humidity (ref: Effective Moisture Penetration Depth (EMPD) Model in the Engineering Reference):

$$U = a\varphi^b + c\varphi^d \quad (8)$$

where

a,b,c,d = Coefficients to define the relationship between the material's moisture content and the surface air relative humidity

U = Moisture content defined as the mass fraction of water contained in a material [kg/kg]

$\varphi$  = Surface air relative humidity [0 to 1]

#### 1.8.7.4 The next four fields are dimensionless coefficients:

#### 1.8.7.5 Field: Moisture Equation Coefficient a

#### 1.8.7.6 Field: Moisture Equation Coefficient b

#### 1.8.7.7 Field: Moisture Equation Coefficient c

#### 1.8.7.8 Field: Moisture Equation Coefficient d

Ann IDF example showing how it is used in conjunction with Material in synchronous pairs:

## 1.8.8 Moisture Penetration Depth (EMPD) Outputs

Output variables applicable to heat transfer surfaces using EMPD model:

- Zone,Average,EMPD Surface Inside Face Water Vapor Density [kg/m3]
- Zone,Average,EMPD Surface Inside Face Humidity Ratio [kgWater/kgDryAir]
- Zone,Average,EMPD Surface Inside Face Relative Humidity [%]

The following variables apply only to surfaces, where the material assigned to the inside layers is MaterialProperty:MoisturePenetrationDepth:Settings. The EMPD (Effective Moisture Penetration Depth) moisture balance solution algorithm is used to calculate the inside surface moisture levels.

### 1.8.8.1 EMPD Surface Inside Face Water Vapor Density [kg/m3]

The vapor density at the inside surface, where the EMPD moisture balance solution algorithm is applied.

### 1.8.8.2 EMPD Surface Inside Face Humidity Ratio [kgWater/kgDryAir]

The humidity ratio at the inside surface, where the EMPD moisture balance solution algorithm is applied.

### 1.8.8.3 EMPD Surface Inside Face Relative Humidity [%]

The relative humidity at the inside surface, where the EMPD moisture balance solution algorithm is applied.

## 1.8.9 MaterialProperty:PhaseChange

**Advanced/Research Usage:** This material is used to describe the temperature dependent material properties that are used in the Conduction Finite Difference solution algorithm. This conduction model is done when the appropriate materials are specified and the Solution Algorithm parameter is set toConductionFiniteDifference. This permits simulating temperature dependent thermal conductivity and phase change materials (PCM) in EnergyPlus.

### 1.8.9.1 Field: Name

This field is a regular material name specifying the material with which this additional temperature dependent property information will be associated.

### 1.8.9.2 Field: Temperature Coefficient for Thermal Conductivity

This field is used to enter the temperature dependent coefficient for thermal conductivity of the material. Units for this parameter are (W/(m·K)). This is the thermal conductivity change per unit temperature excursion from 20 C. The conductivity value at 20 C is the one specified with the basic material properties of the regular material specified in the name field. The thermal conductivity is obtained from:

$$k = k_o + k_1(T_i - 20) \quad (9)$$

where:

$k_o$  is the 20C value of thermal conductivity(normal idf input)

$k_1$  is the change in conductivity per degree temperature difference from 20C

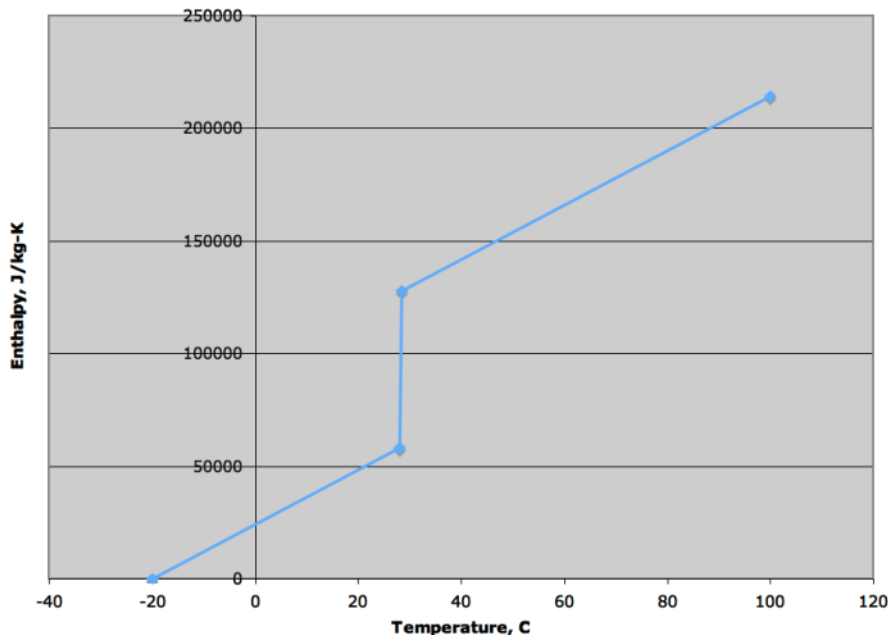

(this field).

### 1.8.9.3 Field Set: Temperature-Enthalpy

The temperature – enthalpy set of inputs specify a two column tabular temperature-enthalpy function for the basic material. Sixteen pairs can be specified. Specify only the number of pairs necessary. The tabular function must cover the entire temperature range that will be seen by the material in the simulation. It is suggested that the function start at a low temperature, and extend to 100C. Note that the function has no negative slopes and the lowest slope that will occur is the base material specific heat. Temperature values should be strictly increasing. Enthalpy contributions of the phase change are always added to the enthalpy that would result from a constant specific heat base material. An example of a simple enthalpy temperature function is shown below.

**Temperature Enthalpy Data**

#### 1.8.9.4 Field: Temperature x

This field is used to specify the temperature of the temperature-enthalpy function for the basic material. Units are C.

#### 1.8.9.5 Field: Enthalpy x

This field specifies the enthalpy that corresponds to the previous temperature of the temperature-enthalpy function. Units are J/kg.

And, an IDF example showing how it is used in conjunction with the Material:

Note, the following Heat Balance Algorithm is necessary (only specified once). Also, when using ConductionFiniteDifference, it is more efficient to set the zone timestep shorter than those used for the ConductionTransferFunction solution algorithm. It should be set to 12 timesteps per hour or greater, and can range up to 60.

```

### 1.8.10 MaterialProperty:VariableThermalConductivity

This object is used to describe the temperature dependent material properties that are used in the CondFD (Conduction Finite Difference) solution algorithm. This conduction model is used when the appropriate CondFD materials are specified and the Solution Algorithm parameter is set to condFD.

#### 1.8.10.1 Field: Name

This field is a regular material name specifying the material with which this additional temperature dependent property information will be associated.

#### 1.8.10.2 Field Set: Temperature-Thermal Conductivity

The temperature – conductivity set of inputs specify a two column tabular temperature-thermal conductivity function for the basic material. Ten pairs can be specified. Specify only the number of pairs necessary. Temperature values should be strictly increasing.

#### 1.8.10.3 Field: Temperature x

This field is used to specify the temperature of the temperature-conductivity function for the basic material. Units are C.

#### 1.8.10.4 Field: Thermal Conductivity x

This field specifies the conductivity that corresponds to the temperature (previous field) of the temperature-conductivity function. Units are W/m-K.

And, an IDF example showing how it is used in conjunction with the Materials:

Note, the following Heat Balance Algorithm is necessary (only specified once). Also, when using Conduction Finite Difference, it is more efficient to set the zone time step shorter than those used for the Conduction Transfer Function solution algorithm. It should be set to 12 time steps per hour or greater, and can range up to 60.

### 1.8.11 Conduction Finite Difference (CondFD) Outputs

The Conduction Finite Difference solution algorithm uses a finite difference solution technique, the surfaces are divided into a nodal arrangement. The only output specific to Conduction Finite Difference solution (that is not include in other surface outputs) is node temperatures.

The following output variables are applicable to all opaque heat transfer surfaces when using Solution Algorithms ConductionFiniteDifference:

- Zone,Sum,CondFD Inner Solver Loop Iteration Count []
- Zone,Average,CondFD Surface Temperature Node <1> [C]

### 1.8.11.1 CondFD Inner Solver Loop Iteration Count []

This outputs the count of iterations on the inner solver loop of CondFD for each surface.

### 1.8.11.2 CondFD Surface Temperature Node <X> [C]

This will output temperatures for a node in the surfaces being simulated with ConductionFiniteDifference. The key values for this output variable are the surface name. The nodes are numbered from outside to inside of the surface. The full listing will appear in the RDD file

## 1.8.12 MaterialProperty:HeatAndMoistureTransfer:Settings

**Advanced/Research Usage:** This object is used to describe two of the seven additional material properties needed for the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm. The settings object is used when the solutions algorithm is set to CombinedHeatAndMoistureFiniteElement and the appropriate material properties are assigned to each material. This permits the simulation of the moisture dependant thermal properties of the material as well as the transfer of moisture through, into and out of the material into the zone or exterior.

In addition to the Porosity and Initial Water content properties described here, five additional properties, described by tabulated relationships between variables, are required. These properties are;

- MaterialProperty:HeatAndMoistureTransfer:SorptionIsotherm
- MaterialProperty:HeatAndMoistureTransfer:Suction
- MaterialProperty:HeatAndMoistureTransfer:Redistribution
- MaterialProperty:HeatAndMoistureTransfer:Diffusion
- MaterialProperty:HeatAndMoistureTransfer:ThermalConductivity

All materials in a construction are required to have all material properties defined for HAMT to work.

Within the MaterialProperty:HeatAndMoistureTransfer:Settings object the following fields are defined.

### 1.8.12.1 Field: Material Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data.

### 1.8.12.2 Field: Porosity

The porosity of a material is the maximum fraction, by volume, of a material that can be taken up with water. The units are [m3/m3].

### 1.8.12.3 Field: Initial Water Content Ratio

For this solution algorithm, the initial water content is assumed to be distributed evenly through the depth of the material. The units are [kg/kg].

Below is an example input for the porosity and initial water content of a material.

```
MaterialProperty:HeatAndMoistureTransfer:Settings,  
Concrete,      !- Name  
0.76,         !- Porosity  
0.2;         !- Initial (or typical) Water content
```

## 1.8.13 MaterialProperty:HeatAndMoistureTransfer:SorptionIsotherm

**Advanced/Research Usage:** This material property is used in conjunction with the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm.

The Isotherm data relates the moisture, or water content [kg/m3] of a material with the relative humidity (RH). The water content is expected to increase as relative humidity increases, starting at zero content at 0.0 relative humidity fraction and reaching a maximum, defined by the porosity, at 1.0 relative humidity fraction, which corresponds to 100% relative humidity. Relative humidities are entered as fraction for this object ranging from 0.0 to 1.0. These two extremes (0.0 and 1.0) are automatically set by the HAMT solution. However, if they are entered they will be used as extra data points. Data should be provided with increasing RH and moisture content up to as high an RH as possible to provide a stable solution. One possible reason for the following error message may be that a material has a very rapid increase in water content for a small change in RH, which can happen if the last entered water content point is at a low RH and the material has a very high porosity.

```
** Warning ** HeatAndMoistureTransfer: Large Latent Heat for Surface ROOF
```

Another potential reason for this error being generated is the use of inappropriate values for Vapor Transfer Coefficients. See the SurfaceProperties:VaporCoefficients object in the Advanced Surface Concepts group.

### 1.8.13.1 Field: Material Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data.

#### 1.8.13.2 Field: Number of data Coordinates

A maximum of 25 coordinates can be specified.

#### 1.8.13.3 Field Set: Relative Humidity-Moisture Content

#### 1.8.13.4 Field: Relative Humidity Fraction x

The relative humidity of the  $x^{\text{th}}$  coordinate. The relative humidity is entered as fraction, not in percent.

#### 1.8.13.5 Field: Moisture Content x

The Moisture Content of the  $x^{\text{th}}$  coordinate. The units are [kg/m3]

Below is an example input for a material isotherm

```
MaterialProperty:HeatAndMoistureTransfer: SorptionIsotherm,

100.28;       !- Moisture content #10
```

### 1.8.14 MaterialProperty:HeatAndMoistureTransfer:Suction

**Advanced/Research Usage:**This material property is used in conjunction with the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm.

The suction data relates the liquid transport coefficient, under suction, to the water content of a material. A data point at zero water content is required. The liquid transport coefficient at the highest entered water content value is used for all liquid transport coefficient values above this water content. These coefficients are used by HAMT when the rain flag is set in the weather file.

#### 1.8.14.1 Field: Material Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data.

#### 1.8.14.2 Field: Number of Suction points

A maximum of 25 points can be specified.

#### 1.8.14.3 Field Set: Moisture Content-Liquid Transport Coefficient

#### 1.8.14.4 Field: Moisture Content x

The moisture content of the  $x^{\text{th}}$  point. The units are [kg/m3].

#### 1.8.14.5 Field: Liquid Transport Coefficient x

The Liquid Transport Coefficient of the  $x^{\text{th}}$  point. The units are [m2/s].

Below is an example input for a material liquid transport coefficient under suction.

```
MaterialProperty:HeatAndMoistureTransfer:Suction,
Concrete,      !- Name
5,            !- Number of Suction points
```

```

0,      !- Moisture content 1
0,      !- Liquid Transport Coefficient 1
72,     !- Moisture content 2
0.0000000000741,    !- Liquid Transport Coefficient 2
85,     !- Moisture content 3
0.0000000000253,    !- Liquid Transport Coefficient 3
100,    !- Moisture content 4
0.000000000101,    !- Liquid Transport Coefficient 4
118,    !- Moisture content 5
0.000000000128;    !- Liquid Transport Coefficient 5

```

### 1.8.15 MaterialProperty:HeatAndMoistureTransfer:Redistribution

**Advanced/Research Usage:**This material property is used in conjunction with the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm.

The redistribution data relates the liquid transport coefficient to the water content of a material under normal conditions. A data point at zero water content is required. The liquid transport coefficient at the highest entered water content value is used for all liquid transport coefficient values above this water content. These coefficients are used by the Heat and Moisture Transfer algorithm when the rain flag is NOT set in the weather file.

#### 1.8.15.1 Field: Material Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data.

#### 1.8.15.2 Field: Number of Redistribution points

A maximum of 25 points can be specified.

#### 1.8.15.3 Field Set: Moisture Content-- Liquid Transport Coefficient

#### 1.8.15.4 Field: Moisture Content x

The moisture content of the x<sup>th</sup> point. The units are [kg/m3].

#### 1.8.15.5 Field: Liquid Transport Coefficient x

The Liquid Transport Coefficient of the x<sup>th</sup> point. The units are [m2/s].

Below is an example input for the object.

```

MaterialProperty:HeatAndMoistureTransfer:Redistribution,
Concrete,      !- Name
5,            !- Number of Redistribution points
0,            !- Moisture content 1
0,            !- Liquid Transport Coefficient 1
72,           !- Moisture content 2
0.0000000000741,    !- Liquid Transport Coefficient 2
85,           !- Moisture content 3
0.0000000000253,    !- Liquid Transport Coefficient 3
100,          !- Moisture content 4
0.000000000101,    !- Liquid Transport Coefficient 4
118,          !- Moisture content 5
0.000000000128;    !- Liquid Transport Coefficient 5

```

### 1.8.16 MaterialProperty:HeatAndMoistureTransfer:Diffusion

**Advanced/Research Usage:**This material property is used in conjunction with the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm.

The MU data relates the vapor diffusion resistance factor (dimensionless) to the relative humidity as fraction(RH). A data point at zero RH is required. The vapor diffusion resistance factor at the highest entered relative humidity (RH) value is used for all vapor diffusion resistance factor values above this RH. The relative humidity maximum value in fraction is 1.0.

#### 1.8.16.1 Field: Material Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data.

#### 1.8.16.2 Field: Number of Data Pairs

A maximum of 25 pairs can be specified.

#### 1.8.16.3 Field Set: Relative Humidity-Vapor Diffusion Resistance Factor

#### 1.8.16.4 Field: Relative Humidity Fraction #x

The moisture content of the  $x^{\text{th}}$  pair. The relative humidity is entered as fraction, not in percent.

#### 1.8.16.5 Field: Vapor Diffusion Resistance Factor #x

The Liquid Transport Coefficient of the  $x^{\text{th}}$  pair.

Below are some examples of the values for materials.

```
MaterialProperty:HeatAndMoistureTransfer:Diffusion,
  Plywood,      !- Name
  3,            !- Number of data Points
  0,            !- Relative Humidity Fraction 1
  700,         !- Water Vapor Diffusion Resistance Factor 1
  0.5,         !- Relative Humidity Fraction 2
  200,         !- Water Vapor Diffusion Resistance Factor 2
  1,           !- Relative Humidity Fraction 3
  20;          !- Water Vapor Diffusion Resistance Factor 3
```

```
MaterialProperty:HeatAndMoistureTransfer:Diffusion,
  Concrete,     !- Name
  1,           !- Number of Mu Points
  0,           !- Relative Humidity Fraction 1
  180;        !- Water Vapor Diffusion Resistance Factor 1
```

#### 1.8.17 MaterialProperty:HeatAndMoistureTransfer:ThermalConductivity

**Advanced/Research Usage:**This material property is used in conjunction with the CombinedHeatAndMoistureFiniteElement heat balance solution algorithm.

The thermal data relates the thermal conductivity [W/m-K] of a material to the moisture or water content [kg/m<sup>3</sup>]. A data point at zero water content is required. The thermal conductivity at the highest entered water content value is used for all thermal conductivity values above this water content. If this object is not defined for a material then the algorithm will use a constant value entered in the Material object for all water contents.

##### 1.8.17.1 Field: Material Name

This field is a unique reference name that the user assigns to a particular material. This name can then be referred to by other input data.

##### 1.8.17.2 Field: Number of Thermal Coordinates

A maximum of 25 coordinates can be specified.

##### 1.8.17.3 Field Set: Moisture Content- Thermal Conductivity

##### 1.8.17.4 Field: Moisture Content x

The moisture content of the  $x^{\text{th}}$  coordinate. The units are [kg/m<sup>3</sup>]

##### 1.8.17.5 Field: Thermal Conductivity x

The Thermal Conductivity of the  $x^{\text{th}}$  coordinate. The units are [W/m-K]

Below is an example of values for a material.

```
MaterialProperty:HeatAndMoistureTransfer:ThermalConductivity
  Concrete,     !- Name
  2,           !- Number of Thermal Coordinates
  0,           !- Moisture content \#1
  1.6,        !- Thermal Conductivity \#1
  180,        !- Moisture content \#2
  2.602;      !- Thermal Conductivity \#2
```

#### 1.8.18 Heat and Moisture (HAMT) Outputs

- Zone,Average,HAMT Surface Average Water Content Ratio [kg/kg]
- Zone,Average,HAMT Surface Inside Face Temperature [C]
- Zone,Average,HAMT Surface Inside Face Relative Humidity [%]
- Zone,Average,HAMT Surface Inside Face Vapor Pressure [Pa]
- Zone,Average,HAMT Surface Outside Face Temperature [C]
- Zone,Average,HAMT Surface Outside Face Relative Humidity [%]

- Zone,Average,HAMT Surface Inside Face Relative Humidity [%]

#### 1.8.18.1 HAMT Surface Average Water Content Ratio [kg/kg]

This output is the summed water content [kg/kg] of all cells in a surface expressed as a fraction of the mass of the water to the material mass.

#### 1.8.18.2 HAMT Surface Inside Face Temperature [C]

This output is the temperature [C] on the internal “surface” of the surface.

#### 1.8.18.3 HAMT Surface Inside Face Relative Humidity [%]

#### 1.8.18.4 HAMT Surface Inside Face Relative Humidity [%]

This output is the relative humidity on the internal “surface” of the surface expressed as a percentage.

#### 1.8.18.5 HAMT Surface Inside Face Vapor Pressure [Pa]

This output is the vapor pressure [Pa] on the internal “surface” of the surface.

#### 1.8.18.6 HAMT Surface Outside Face Temperature [C]

This output is the temperature on the external “surface” of the surface.

#### 1.8.18.7 HAMT Surface Outside Face Relative Humidity [%]

This output is the relative humidity on the external “surface” of the surface.

Zone,Average,HAMT Surface Temperature Cell N [C]

Zone,Average,HAMT Surface Water Content Cell N [kg/kg]

Zone,Average,HAMT Surface Relative Humidity Cell N [%]

Detailed profile data for the variables Temperature [C], Relative Humidity [%] and Water Content [kg/kg] within each surface can also be reported. To calculate the heat and moisture transfer through surfaces HAMT splits up surfaces into discrete cells. Each cell is composed of a single material and has a position within the surface. HAMT automatically assigns cells to construction objects so that there are more cells closer to boundaries between materials and also at the “surfaces” of the surface. It is not possible for users to define their own cells.

#### 1.8.18.8 HAMT Surface Relative Humidity Cell <N> [%]

This is the relative humidity of the cell in the surface.

#### 1.8.18.9 HAMT Surface Temperature Cell <N> [C]

This is the temperature of the cell in the surface.

#### 1.8.18.10 HAMT Surface Water Content Cell <N> [kg/kg]

This is the relative water content of the cell in the surface.

Each surface is made from a particular construction. The construction-surface relationship is output by HAMT to the eplusout.eio file with the following format.

```
! <HAMT cells>, Surface Name, Construction Name, Cell Numbers
! <HAMT origins>, Surface Name, Construction Name, Cell origins (m)
```

The output also contains the HAMT cell origins and cell number for each construction – surface combination. The coordinate system origin is defined as the exterior surface of the construction. Users can select any one of the Temperature, Relative Humidity or Water Content variables for any cell to be reported, using the following naming scheme for the output variable.

HAMT Profile Construction <Variable> Cell <Cell#>

It is better to specify the “key” or Surface Name in this output.

So for example to output the temperature of the 10<sup>th</sup> cell in a surface, eg “East Wall” would require the following output variable.

```
Output:Variable,
  East Wall,           !- Key Value
  HAMT Profile Construction Temperature Cell 10, !- Variable Name
  Hourly;             !- Reporting Frequency
```

By selecting a whole range of these reports and using the information in the eplusout.eio file it is possible to build up a temperature profile of the surface.

### 1.8.19 Materials for Glass Windows and Doors

All the materials for glass windows and doors have the prefix "WindowMaterial". The following WindowMaterial descriptions (Glazing, Glazing:RefractionExtinctionMethod, Gas, GasMixture, Shade, Screen and Blind) apply to glass windows and doors. The property definitions described herein for Glazing, Gas and GasMixture are supported by the National Fenestration Rating Council as standard.

"Front side" is the side of the layer opposite the zone in which the window is defined. "Back side" is the side closest to the zone in which the window is defined. Therefore, for exterior windows, "front side" is the side closest to the outdoors. For interior windows, "front side" is the side closest to the zone adjacent to the zone in which the window is defined.

The solar radiation transmitted by the window layers enters the zone and is a component of the zone load. The solar radiation absorbed in each solid layer (glass, shade, screen or blind) participates in the window layer heat balance calculation. The visible transmittance and reflectance properties of the window are used in the daylighting calculation.

### 1.8.20 WindowMaterial:Glazing

In the following, for exterior windows, "front side" is the side of the glass closest to the outside air and "back side" is the side closest to the zone the window is defined in. For interzone windows, "front side" is the side closest to the zone adjacent to the zone the window is defined in and "back side" is the side closest to the zone the window is defined in.

#### 1.8.20.1 Field: Name

The name of the glass layer. It corresponds to a layer in a window construction.

#### 1.8.20.2 Field: Optical Data Type

Valid values for this field are SpectralAverage, Spectral, BSDF.

If Optical Data Type = SpectralAverage, the values you enter for solar transmittance and reflectance are assumed to be averaged over the solar spectrum, and the values you enter for visible transmittance and reflectance are assumed to be averaged over the solar spectrum and weighted by the response of the human eye. There is an EnergyPlus Reference Data Set for WindowMaterial:Glazing that contains spectral average properties for many different types of glass.

If Optical Data Type = Spectral, then, in the following field, you must enter the name of a spectral data set defined with the WindowGlassSpectralData object. In this case, the values of solar and visible transmittance and reflectance in the fields below should be blank.

If Optical Data Type = BSDF, the Construction:ComplexFenestrationState object must be used to define the window construction layers. The Construction:ComplexFenestrationState object contains references to the BSDF files which contain the optical properties of the Complex Fenestration layers. In this case,

#### 1.8.20.3 Field: Window Glass Spectral Data Set Name

If Optical Data Type = Spectral, this is the name of a spectral data set defined with a WindowGlassSpectralData object.

#### 1.8.20.4 Field: Thickness

The surface-to-surface thickness of the glass (m).

#### 1.8.20.5 Field: Solar Transmittance at Normal Incidence

Transmittance at normal incidence averaged over the solar spectrum. Used only when Optical Data Type = SpectralAverage.

For uncoated glass, when alternative optical properties are available—such as thickness, solar index of refraction, and solar extinction coefficient—they can be converted to equivalent solar transmittance and reflectance values using the equations given in "Conversion from Alternative Specification of Glass Optical Properties.")

#### 1.8.20.6 Field: Front Side Solar Reflectance at Normal Incidence

Front-side reflectance at normal incidence averaged over the solar spectrum. Used only when Optical Data Type = SpectralAverage.

#### 1.8.20.7 Field: Back Side Solar Reflectance at Normal Incidence

Back-side reflectance at normal incidence averaged over the solar spectrum. Used only when Optical Data Type = SpectralAverage.

#### 1.8.20.8 Field: Visible Transmittance at Normal Incidence

Transmittance at normal incidence averaged over the solar spectrum and weighted by the response of the human eye. Used only when Optical Data Type =

SpectralAverage.

For uncoated glass, when alternative optical properties are available—such as thickness, visible index of refraction, and visible extinction coefficient—they can be converted to equivalent visible transmittance and reflectance values using the equations given in “Conversion from Alternative Specification of Glass Optical Properties.”)

**1.8.20.9 Field: Front Side Visible Reflectance at Normal Incidence**

Front-side reflectance at normal incidence averaged over the solar spectrum and weighted by the response of the human eye. Used only when Optical Data Type = SpectralAverage.

**1.8.20.10 Field: Back Side Visible Reflectance at Normal Incidence**

Back-side reflectance at normal incidence averaged over the solar spectrum and weighted by the response of the human eye. Used only when Optical Data Type = SpectralAverage.

**1.8.20.11 Field: Infrared Transmittance at Normal Incidence**

Long-wave transmittance at normal incidence.

**1.8.20.12 Field: Front Side Infrared Hemispherical Emissivity**

Front-side long-wave emissivity.

**1.8.20.13 Field: Back Side Infrared Hemispherical Emissivity**

Back-side long-wave emissivity.

**1.8.20.14 Field: Conductivity**

Thermal conductivity (W/m-K).

**1.8.20.15 Field: Dirt Correction Factor for Solar and Visible Transmittance**

This is a factor that corrects for the presence of dirt on the glass. The program multiplies the fields “Solar Transmittance at Normal Incidence” and “Visible Transmittance at Normal Incidence” by this factor if the material is used as the outer glass layer of an exterior window or glass door.<sup>[1]</sup> If the material is used as an inner glass layer (in double glazing, for example), the dirt correction factor is not applied because inner glass layers are assumed to be clean. Using a material with dirt correction factor < 1.0 in the construction for an interior window will result in an error message.

Representative values of the dirt correction factor are shown in Table 7.

Table 7. Dirt Correction Factors

Type of Location	Angle of Glazing		
	Vertical	45	Horizontal
Non-industrial	0.9	0.8	0.7
Industrial	0.7	0.6	0.5
Very Dirty	0.6	0.5	0.4

From Appendix A, “Daylighting in Sports Halls, Report 2,” SportScotland, Nov. 2002 (www.sportscotland.org.uk)

The default value of the dirt correction factor is 1.0, which means the glass is clean.

It is assumed that dirt, if present, has no effect on the IR properties of the glass.

**1.8.20.16 Field: Solar Diffusing**

Takes values No (the default) and Yes. If No, the glass is transparent and beam solar radiation incident on the glass is transmitted as beam radiation with no diffuse component. If Yes, the glass is translucent and beam solar radiation incident on the glass is transmitted as hemispherically diffuse radiation with no beam component.<sup>[2]</sup> See Figure 10. Solar Diffusing = Yes should only be used on the *innermost* pane of glass in an exterior window; it does not apply to interior windows.

For both Solar Diffusing = No and Yes, beam is reflected as beam with no diffuse component (see Figure 10). Solar Diffusing cannot be used with Window Shading Control devices (except Switchable Glazing). When attempted, the window property will be set to No for Solar Diffusing. The Surface Details report will reflect the override.

If, in the Building object, Solar Distribution = FullInteriorAndExterior, use of Solar Diffusing = Yes for glass in an exterior window will change the distribution of

interior solar radiation from the window. The result is that beam solar radiation that would be transmitted by a transparent window and get absorbed by particular interior surfaces will be diffused by a translucent window and be spread over more interior surfaces. This can change the time dependence of heating and cooling loads in the zone.

In a zone with Daylighting:Detailed, translucent glazing---which is often used in skylights---will provide a more uniform daylight illuminance over the zone and will avoid patches of sunlight on the floor.

Figure 10. Comparison between transmittance properties of transparent glass (Solar Diffusing = No) and translucent glass (Solar Diffusing = Yes).

#### 1.8.20.17 Field: Young's modulus

A measure of the stiffness of an elastic material. It is defined as the ratio of the uniaxial stress over the uniaxial strain in the range of stress in which Hooke's Law holds. It is used only with complex fenestration systems defined through the Construction:ComplexFenestrationState object. The default value for glass is 7.2e10 Pa.

#### 1.8.20.18 Field: Poisson's ratio

The ratio, when a sample object is stretched, of the contraction or transverse strain (perpendicular to the applied load), to the extension or axial strain (in the direction of the applied load). This value is used only with complex fenestration systems defined through the Construction:ComplexFenestrationState object. The default value for glass is 0.22.

IDF examples of Spectral average and using a Spectral data set:

## 1.8.21 WindowMaterial:Glazing:RefractionExtinctionMethod

This is an alternative way of specifying glass properties. Index of refraction and extinction coefficient are given instead of the transmittance and reflectance values used in WindowMaterial:Glazing. However, unlike WindowMaterial:Glazing, WindowMaterial:Glazing:RefractionExtinctionMethod is restricted to cases where the front and back optical properties of the glass are the same. This means it cannot be used for glass with a coating on one side. In that case WindowMaterial:Glazing should be used. Also, unlike WindowMaterial:Glazing, WindowMaterial:Glazing:RefractionExtinctionMethod does not allow input of glass wavelength-by-wavelength (spectral) properties.

### 1.8.21.1 Field: Name

The name of the glass layer. It corresponds to a layer in a window construction.

### 1.8.21.2 Field: Thickness

The surface-to-surface thickness of the glass (m).

### 1.8.21.3 Field: Solar Index of Refraction

Index of refraction averaged over the solar spectrum.

### 1.8.21.4 Field: Solar Extinction Coefficient

Extinction coefficient averaged over the solar spectrum ( $m^{-1}$ ).

### 1.8.21.5 Field: Visible Index of Refraction

Index of refraction averaged over the solar spectrum and weighted by the response of the human eye.

### 1.8.21.6 Field: Visible Extinction Coefficient

Extinction coefficient averaged over the solar spectrum and weighted by the response of the human eye ( $m^{-1}$ ).

### 1.8.21.7 Field: Infrared Transmittance at Normal Incidence

Long-wave transmittance at normal incidence.

### 1.8.21.8 Field: Infrared Hemispherical Emissivity

Long-wave hemispherical emissivity, assumed the same on both sides of the glass.

### 1.8.21.9 Field: Conductivity

Thermal conductivity (W/m-K).

### 1.8.21.10 Field: Dirt Correction Factor for Solar and Visible Transmittance

This is a factor that corrects for the presence of dirt on the glass. It multiplies the solar and visible transmittance at normal incidence (which the program calculates from the input values of thickness, solar index of refraction, solar extinction coefficient, etc.) if the material is used as the outer glass layer of an exterior window or glass door. If the material is used as an inner glass layer (in double glazing, for example), the dirt correction factor is not applied because inner glass layers are assumed to be clean. Using a material with dirt correction factor  $< 1.0$  in the construction for an interior window will result in an error message.

Representative values of the dirt correction factor are shown in Table 7.

The default value of the dirt correction factor is 1.0, which means the glass is clean. It is assumed that dirt, if present, has no effect on the IR properties of the glass.

### 1.8.21.11 Field: Solar Diffusing

Takes values No (the default) and Yes. If No, the glass is transparent. If Yes, the glass is translucent and beam solar radiation incident on the glass is transmitted as hemispherically diffuse radiation with no beam component. (EnergyPlus does not model the "partially translucent" case in which beam solar

radiation incident on the glass is transmitted as a combination of beam and diffuse.) Solar Diffusing = Yes should only be used on the innermost pane of glass in an exterior window; it does not apply to interior windows.

If, in the Building object, Solar Distribution = FullInteriorAndExterior, use of Solar Diffusing = Yes for glass in an exterior window will change the distribution of interior solar radiation from the window. The result is that beam solar radiation that would be transmitted by a transparent window and get absorbed by particular interior surfaces will be diffused by a translucent window and be spread over more interior surfaces. This can change the time dependence of heating and cooling loads in the zone.

In a zone with Daylighting:Detailed, translucent glazing, which is often used in skylights, will provide a more uniform daylight illuminance over the zone and will avoid patches of sunlight on the floor.

An IDF example:

```
WindowMaterial:Glazing:RefractionExtinctionMethod,
4MM CLEAR GLASS, !- Material name
  0.004, !- Thickness {m}
  1.526, !- Solar index of refraction
  30.0 , !- Solar extinction coefficient (1/m)
  1.526, !- Visible index of refraction
  30.0 , !- Visible extinction coefficient (1/m)
  0.0,   !- IR transmittance at normal incidence
  0.84,  !- IR emissivity
  0.9;   !- Conductivity {W/m-K}
```

## 1.8.22 Glass Optical Properties Conversion

### 1.8.22.1 Conversion from Glass Optical Properties Specified as Index of Refraction and Transmittance at Normal Incidence

The optical properties of uncoated glass are sometimes specified by index of refraction,  $n$ , and transmittance at normal incidence,  $T$ .

The following equations show how to convert from this set of values to the transmittance and reflectance values required by WindowMaterial:Glazing. These equations apply only to uncoated glass, and can be used to convert either spectral-average solar properties or spectral-average visible properties (in general,  $n$  and  $T$  are different for the solar and visible). Note that since the glass is uncoated, the front and back reflectances are the same and equal to  $r$  that is solved for in the following equations.

Given  $n$  and  $T$ , find  $R$ :

$$\begin{aligned}
 r &= \left( \frac{n-1}{n+1} \right)^2 \\
 \tau &= \frac{\left[ (1-r)^4 + 4r^2 T^2 \right]^{1/2} - (1-r)^2}{2r^2 T} \\
 R &= r + \frac{(1-r)^2 r T^2}{1-r^2 T^2}
 \end{aligned} \tag{10}$$

**Example:**

$T = 0.86156$

$n = 1.526$

$$\begin{aligned}
 r &= \left( \frac{1.526-1}{1.526+1} \right)^2 \\
 \tau &= 0.93974 \\
 R &= 0.07846
 \end{aligned} \tag{11}$$

## 1.8.23 WindowMaterial:GlazingGroup:Thermochromic

Thermochromic (TC) materials have active, reversible optical properties that vary with temperature. Thermochromic windows are adaptive window systems for incorporation into building envelopes. Thermochromic windows respond by absorbing sunlight and turning the sunlight energy into heat. As the thermochromic film warms it changes its light transmission level from less absorbing to more absorbing. The more sunlight it absorbs the lower the light level going through it. By using the sun's own energy the window adapts based solely on the directness and amount of sunlight. Thermochromic materials will normally reduce optical transparency by absorption and/or reflection, and are specular (maintaining vision).

A thermochromic window is defined with a Construction object which references a special layer defined with a WindowMaterial:GlazingGroup:Thermochromic object. The WindowMaterial:GlazingGroup:Thermochromic object further references a series of WindowMaterial:Glazing objects corresponding to each specification temperature of the TC layer.

This object specifies a layer of thermochromic glass, part of a thermochromic window. An example file ThermochromicWindow.idf is included in the EnergyPlus installation.

### 1.8.23.1 Field: Name

A unique user assigned name for a particular thermochromic glass material.

### 1.8.23.2 Field Set (Optical Data Temperature, Window Material Glazing Name) is extensible.

#### 1.8.23.3 Field:Optical Data Temperature <N>

The temperature of the TC glass layer corresponding to the optical data of the TC layer. Unit is °C.

#### 1.8.23.4 Field: Window Material Glazing Name <N>

The window glazing (defined with WindowMaterial:Glazing) name that provides the TC glass layer performance at the above specified temperature.

## 1.8.24 WindowMaterial:GlazingGroup:Thermochromic Outputs

### 1.8.24.1 Surface Window Thermochromic Layer Temperature [C]

The temperature of the TC glass layer of a TC window at each time step.

### 1.8.24.2 Surface Window Thermochromic Layer Property Specification Temperature [C]

The temperature under which the optical data of the TC glass layer are specified.

The overall properties (U-factor/SHGC/VT) of the thermochromic windows at different specification temperatures are reported in the EIO file. These window constructions are created by EnergyPlus during run time. They have similar names with suffix “\_TC\_XX” where XX represents a specification temperature.

## 1.8.25 WindowMaterial:Gas

This object specifies the properties of the gas between the panes of a multi-pane window. Gas Type = Custom allows you to specify the properties of gases other than air, Argon, Krypton or Xenon. There is an EnergyPlus Reference Data Set for Material:WindowGas that contains several types of gas of different thicknesses. See Material:WindowGasMixture for the case that the gas fill is a mixture of different gases.

### 1.8.25.1 Field: Name

The name of the gas fill. It refers to a layer in a window construction.

### 1.8.25.2 Field: Gas Type

The type of gas. The choices are Air, Argon, Krypton, or Xenon. If Gas Type = Custom you can use Conductivity Coefficient A, etc. to specify the properties of a different type of gas.

### 1.8.25.3 Field: Thickness

The thickness (m) of the gas layer.

### 1.8.25.4 Properties for Custom Gas Types

The following entries are used only if Gas Type = Custom. The A and B coefficients are those in the following expression that gives a property value as a function of temperature in degrees K:

$$Property = Coefficient_A + Coefficient_B * Temperature_K \quad (12)$$

**1.8.25.5 Field: Conductivity Coefficient A**

The A coefficient for gas conductivity (W/m-K). Used only if Gas Type = Custom.

**1.8.25.6 Field: Conductivity Coefficient B**

The B coefficient for gas conductivity (W/m-K<sup>2</sup>). Used only if Gas Type = Custom.

**1.8.25.7 Field: Conductivity Coefficient C**

The C coefficient for gas conductivity (W/m-K<sup>3</sup>). Used only if Gas Type = Custom.

**1.8.25.8 Field: Viscosity Coefficient A**

The A coefficient for gas viscosity (kg/m-s). Used only if Gas Type = Custom.

**1.8.25.9 Field: Viscosity Coefficient B**

The B coefficient for gas viscosity (kg/m-s-K). Used only if Gas Type = Custom.

**1.8.25.10 Field: Viscosity Coefficient C**

The C coefficient for gas viscosity (kg/m-s-K<sup>2</sup>). Used only if Gas Type = Custom.

**1.8.25.11 Field: Specific Heat Coefficient A**

The A coefficient for gas specific heat (J/kg-K). Used only if Gas Type = Custom.

**1.8.25.12 Field: Specific Heat Coefficient B**

The B coefficient for gas specific heat (J/kg-K<sup>2</sup>). Used only if Gas Type = Custom.

**1.8.25.13 Field: Specific Heat Coefficient C**

The C coefficient for gas specific heat (J/kg-K<sup>3</sup>). Used only if Gas Type = Custom.

**1.8.25.14 Field: Specific Heat Ratio**

The specific heat ratio for gas. Used only if Gas Type = Custom.

**1.8.25.15 Field: Molecular Weight**

The molecular weight for gas. The molecular weight is the mass of 1 mol of the substance. This has a numerical value which is the average molecular mass of the molecules in the substance multiplied by Avogadro's constant. (kg/kmol) (Shown in the IDD as g/mol for consistency)

**1.8.25.16 Field: Specific Heat Ratio**

The specific heat ratio for gas. The specific heat ratio of a gas is the ratio of the specific heat at constant pressure, to the specific heat at constant volume. Used only if Gas Type = Custom.

An IDF example:

```
WindowMaterial:Gas,AIRGAP,
  AIR,          ! Gas type (Air - Argon - Krypton - Xenon - Custom)]
  0.0125;      ! Thickness {m} 1/2 inch
```

An IDF example to be used with a WindowMaterial:Gap definition (see below)

```
WindowMaterial:Gas,
Gas_1_W_0_0100,          !- gap name - Air
Air,                    !- type
0.0100;                 !- thickness
```

An IDF example for a Custom Gas

```
WindowMaterial:Gas,
```

```

Gas_16_W_0_0003,      !- gap name
Custom,               !- type
0.0003,              !- thickness
2.873000e-003,       !- Conductivity Coefficient A

```

## 1.8.26 WindowMaterial:GasMixture

This object allows you to specify the fill between the panes of a multi-pane window to be a mixture of two, three or four different gases chosen from air, argon, krypton and xenon. It can also be used if only one type of gas in the fill. In this case you can also use WindowMaterial:Gas. Note that the fractions of gas types in the mixture should add up to 1.0.

### 1.8.26.1 Field: Name

The name of the gas mixture. It refers to a layer in a window construction.

### 1.8.26.2 Field: Thickness

The thickness (m) of the gas mixture layer.

### 1.8.26.3 Field: Number of Gases in Mixture

The number of different types of gas in the mixture ( a value from 1 to 4)

### 1.8.26.4 Set: Gas Type-Fraction (up to 4)

### 1.8.26.5 Field: Gas 1 Type

The type of the first gas in the mixture. Choices are Air, Argon, Krypton and Xenon.

### 1.8.26.6 Field: Gas 1 Fraction

The fraction of the first gas in the mixture.

An IDF example:

```

WindowMaterial:GasMixture,ArgonKryptonMix,
0.0125,    ! Thickness {m} 1/2 inch
2,         ! Number of Gases in Mixture
Argon,     ! Gas 1 Type
0.6,      ! Gas 1 Fraction
Krypton,   ! Gas 2 Type
0.4;      ! Gas 2 Fraction

```

## 1.8.27 WindowMaterial:Gap

This input object is used to define the gap between two layers in a complex fenestration system, where the Construction:ComplexFenestrationState object is used. It references the gas or gas mixtures defined in the WindowMaterial:Gas and WindowMaterial:GasMixture objects. It is referenced as a layer in the Construction:ComplexFenestrationState object ;it cannot be referenced as a layer from the Construction object.

### 1.8.27.1 Field: Name

Unique name of the gap.

### 1.8.27.2 Field: Thickness

The thickness (m) of the gap layer.

### 1.8.27.3 Field: Pressure

The pressure (Pa) of the gas in the gap layer, used to calculate the gas properties of the glazing system gap. Default is atmospheric pressure, 101325 Pa. When modeling vacuum glazing, this value should represent the pressure in the evacuated glazing system. If this pressure is less than the ThermalModelParams:PressureLimit value, the the glazing system will be modeled as a vacuum glazing.

#### 1.8.27.4 Field: Deflection State

This field is used when modeling the deflection of the glass layers in a window if the WindowThermalModel:Params value for “deflection model” is “MeasuredDeflection”.

#### 1.8.27.5 Field: Support Pillar

References the support pillar of the gap layer if vacuum glazing is being modeled. If left empty, then it is considered that gap layer does not have support pillars.

#### 1.8.27.6 Field: Gas (or GasMixture)

References gas (WindowMaterial:Gas) or gas mixture (WindowMaterial:GasMixture) of the gap layer.

An IDF example for simple glazing:

```
WindowMaterial:Gas,
Gas_1_W_0_0120,           !- gap name - Air
Air,                      !- type
0.0120;                  !- thickness

WindowMaterial:Gap,
Gap_1_Layer,             !- gap name: Air
0.0120,                  !- thickness
Gas_1_W_0_0120,         !- Gas (or Gas Mixture) name
101325.0000;            !- pressure
```

An IDF example for vacuum glazing:

```
WindowMaterial:Gap,
Gap_16_Layer,           !- gap name: Vacuum_0.001_pr-0.5_ps-50.8
0.0003,                 !- thicknessGas_16_W_0_0003,
0.1333,                 !- pressure
,                       !- deflection state
SupportPillar_16_Gap_1; !- SupportPillar

WindowGap:SupportPillar,
SupportPillar_16_Gap_1, !- Name
0.0508,                 !- spacing
0.0005;                 !- radius
```

#### 1.8.28 WindowGap:DeflectionState

This input object is used to enter data describing deflection state of the gap. It is referenced from WindowMaterial:Gap object only and it is used only when deflection model is set to MeasuredDeflection (see WindowThermalModel:Params), otherwise it is ignored.

##### 1.8.28.1 Field: Name

Unique name of the deflection state.

##### 1.8.28.2 Field: Deflected Thickness

The thickness (m) of the gap in deflected state. It represents value of deflection at point of maximum which is usually at the center poing of glazing system. It is used only with tarcoq algorithm set to Measured Deflection (WindowThermalModel:Params), otherwise this field will be ignored.

An IDF example where WindowThermalModel:Params Deflection Model = MeasuredDeflection:

```
WindowMaterial:Gap,
Gap_1_Layer,           !- gap name: Air
0.0120,                !- thickness
Gas_1_W_0_0120,       !- Gas (or Gas Mixture) name
101325.0000,          !- pressure
Gap_1_Deflection;     !- deflection state

WindowGap:DeflectionState,
  Gap_1_Deflection,    !- name
  0.011;              !- gap thickness in deflected state
```

#### 1.8.29 WindowGap:SupportPillar

This input object is used to enter data describing support pillar of the gap. Support pillars are used in vacuum glazing in order to prevent deflection of glass layers.

Figure 11. Support Pillar

#### 1.8.29.1 Field: Name

Unique name of the support pillar.

#### 1.8.29.2 Field: Spacing

Distance (m) between support pillar centers (see the Engineering reference document for more information).

#### 1.8.29.3 Field: Radius

The radius (m) of the support pillar (see Engineering reference document for more information).

An IDF example for vacuum glazing (see Vacuum Glazing example in WindowMaterial:Gap above)

```
WindowGap:SupportPillar,      !- gap support pillar
  SupportPillar_16_Gap_1,    !- basis matrix name
  0.05,                      !- pillar spacing
  0.005;                     !- pillar radius
```

### 1.8.30 WindowMaterial:SimpleGlazingSystem

This model should be used with caution. There may be significant differences in performance between the simple window system and the usual more detailed model.

This input object differs from the other WindowMaterial objects in that it describes an entire glazing system rather than individual layers. This object is used when only very limited information is available on the glazing layers or when specific performance levels are being targeted. The layer by layer description offers superior method of modeling windows that should be used instead of this object when sufficient data are available. This object accesses a model that turns simple performance indices into a fuller model of the glazing system.

The performance indices are U-factor and Solar Heat Gain Coefficient, and optionally Visible Transmittance. The values for these performance indices can be selected by the user to represent either glazing-only windows (with no frame) or an average window performance that includes the frame. Inside the program the model produces an equivalent window glazing layer with no frame. The properties of the modeled glazing layer are reported to the EIO file using the IDF input object syntax for the WindowMaterial:Glazing input object. This equivalent layer could be reused in subsequent models if desired, however there will be important differences in the modeled window performance because the simple glazing system model includes its own special model for angular dependence when incident beam solar is not normal to the plane of the window.

When this object is referenced in a Construction object, it cannot be used with other glazing or gas material layers. Shades or blinds cannot be located between the glass, but these can be used on the inside or the outside of the glazing system. If the glazing system does have between-the-glass shades or blinds, then the U and SHGC values entered in this object should include the impacts of those layers. Adding window treatment layers such as shades or screens will alter the overall performance to be different than the performance levels prescribed in this object.

#### 1.8.30.1 Field: Name

The name of the glazing system. This value is unique across all constructions.

#### 1.8.30.2 Field: U-Factor

This field describes the value for window system U-Factor, or overall heat transfer coefficient. Units are in  $W/m^2 \cdot K$ . This is the rated (NFRC) value for U-factor under winter heating conditions. The U-factor is assumed to be for vertically mounted products. Although the maximum allowable input is  $U-7.0 W/m^2 \cdot K$ , the

effective upper limit of the glazings generated by the underlying model is around U-5.8 W/m<sup>2</sup>·K.

### 1.8.30.3 Field: Solar Heat Gain Coefficient

This field describes the value for SHGC, or solar heat gain coefficient. There are no units. This is the rated (NFRC) value for SHGC under summer cooling conditions and represents SHGC for normal incidence and vertical orientation.

### 1.8.30.4 Field: Visible Transmittance

This field is optional. If it is omitted, then the visible transmittance properties are taken from the solar properties. If it is included then the model includes it when developing properties for the glazing system. This is the rated (NFRC) value for visible transmittance at normal incidence.

An example of this object.

```
WindowMaterial:SimpleGlazingSystem,  
  SimpleWindow:DOUBLE PANE WINDOW , !- Name  
  2.716 , !- U-Factor  
  0.763 , !- Solar Heat Gain Coefficient  
  0.812 ; !- Visible Transmittance
```

## 1.8.31 WindowMaterial:Shade

This object specifies the properties of window shade materials. Reflectance and emissivity properties are assumed to be the same on both sides of the shade. Shades are considered to be perfect diffusers (all transmitted and reflected radiation is hemispherically-diffuse) with transmittance and reflectance independent of angle of incidence. There is an EnergyPlus Reference Data Set for WindowMaterial:Shade that contains properties of generic window shades.

Window shades can be on the inside of the window ("interior shades"), on the outside of the window ("exterior shades"), or between glass layers ("between-glass shades"). When in place, the shade is assumed to cover all of the glazed part of the window, including dividers; it does not cover any of the window frame, if present. The plane of the shade is assumed to be parallel to the glazing.

WindowMaterial:Shade can be used for diffusing materials such as drapery and translucent roller shades. For slat-type shading devices, like Venetian blinds, that have a strong angular dependence of transmission, absorption and reflection, it is better to use WindowMaterial:Blind. WindowMaterial:Screen should be used to model wire mesh insect screens where the solar and visible transmission and reflection properties vary with the angle of incidence of solar radiation.

Transmittance and reflectance values for drapery material with different color and openness of weave can be obtained from manufacturers or determined from 2001 ASHRAE Fundamentals, Chapter 30, Fig. 31.

There are two methods of assigning a shade to a window:

### 1.8.31.1 Method 1:

- 1) Define the construction of the window without the shade, the so-called "bare" construction.
- 2) Reference the bare construction in the FenestrationSurface:Detailed for the window.
- 3) Define the WindowMaterial:Shade.
- 4) Define a WindowProperty:ShadingControl for the window in which you (a) specify that this WindowMaterial:Shade is the window's shading device and (b) specify how the shade is controlled.

### 1.8.31.2 Method 2:

- 1) Define the Construction of the window without the shade, the so-called "bare" construction.
- 2) Reference the bare construction in the FenestrationSurface:Detailed for the window.
- 3) Define the WindowMaterial:Shade.
- 4) Define another Construction, called the "shaded construction," that includes the WindowMaterial:Shade.
- 5) Define a WindowProperty:ShadingControl for the window in which you (a) reference the shaded construction and (b) specify how the shade is controlled.

Note that WindowProperty:ShadingControl has to be used with either method, even if the shade is in place at all times. You will get an error message if you try to reference a shaded construction directly from FenestrationSurface:Detailed.

### 1.8.31.3 Field: Name

Name of the shade. It is referenced as an inside or outside layer in a window construction.

### 1.8.31.4 Field: Solar Transmittance

Transmittance averaged over the solar spectrum. Assumed independent of incidence angle.

#### 1.8.31.5 Field: Solar Reflectance

Reflectance averaged over the solar spectrum. Assumed same on both sides of shade and independent of incidence angle.

#### 1.8.31.6 Field: Visible Transmittance

Transmittance averaged over the solar spectrum and weighted by the response of the human eye. Assumed independent of incidence angle.

#### 1.8.31.7 Field: Visible Reflectance

Reflectance averaged over the solar spectrum and weighted by the response of the human eye. Assumed same on both side of shade and independent of incidence angle.

#### 1.8.31.8 Field: Thermal Hemispherical Emissivity

Effective long-wave emissivity. Assumed same on both sides of shade. We can approximate this effective emissivity,  $\epsilon_{eff}$ , as follows. Let  $\eta$  be the “openness” the shade, i.e., the ratio of the area of openings in the shade to the overall shade area (see Field: Air-Flow Permeability, below). Let the emissivity of the shade material be  $\epsilon$ . Then

$$\epsilon_{eff} \approx \epsilon (1 - \eta) \quad (13)$$

For most non-metallic materials  $\epsilon$  is about 0.9.

#### 1.8.31.9 Field: Thermal Transmittance

Effective long-wave transmittance. Assumed independent of incidence angle. We can approximate this effective long-wave transmittance,  $T_{eff}$ , as follows. Let  $\eta$  be the “openness” the shade, i.e., the ratio of the area of openings in the shade to the overall shade area. Let the long-wave transmittance of the shade material be  $\tau$ . Then

$$T_{eff} \approx \eta + T (1 - \eta) \quad (14)$$

For most materials\*  $\tau^*$  is very close to zero, which gives

$$T_{eff} \approx \eta \quad (15)$$

#### 1.8.31.10 Field: Thickness

Thickness of the shade material (m). If the shade is not flat, such as for pleated pull-down shades or folded drapery, the average thickness normal to the plane of the shade should be used.

#### 1.8.31.11 Field: Conductivity

Shade material conductivity (W/m-K).

#### 1.8.31.12 Field: Shade to Glass Distance

Distance from shade to adjacent glass (m). This is denoted by  $s$  in Figure 12 and Figure 13, below. If the shade is not flat, such as for pleated pull-down shades or folded drapery, the average shade-to-glass distance should be used. (The shade-to-glass distance is used in calculating the natural convective air flow between glass and shade produced by buoyancy effects.). Note used for between-glass shades.

In the following,  $H$  is the glazing height and  $W$  is the glazing width.

#### 1.8.31.13 Field: Top Opening Multiplier

Effective area for air flow at the top of the shade divided by  $sW$ , the horizontal area between glass and shade (see Figures below).

#### 1.8.31.14 Field: Bottom Opening Multiplier

Effective area for air flow at the bottom of the shade divided by  $sW$ , the horizontal area between glass and shade (see Figures below).

#### 1.8.31.15 Field: Left-Side Opening Multiplier

Effective area for air flow at the left side of the shade divided by  $sH$ , the vertical area between glass and shade (see Figures below).

#### 1.8.31.16 Field: Right-Side Opening Multiplier

Effective area for air flow at the right side of the shade divided by  $sH$ , the vertical area between glass and shade (see Figures below).

### 1.8.31.17 Field: Field: Air-Flow Permeability

The fraction of the shade surface that is open to air flow, i.e., the total area of openings (“holes”) in the shade surface divided by the shade area  $sH$ . If air cannot pass through the shade material, Air-Flow Permeability = 0. For drapery fabric and screens the Air-Flow Permeability can be taken as the “openness” of the fabric (see 2001 ASHRAE Fundamentals, Chapter 30, Fig. 31), which is 0.0 to 0.07 for closed weave, 0.07 to 0.25 for semi-open weave, and 0.25 and higher for open weave.

Figure 12. Vertical section (a) and perspective view (b) of glass and interior shade layers showing variables used in the gap air flow analysis. In (b), the air-flow opening areas  $A_{bot}$ ,  $A_{top}$ ,  $A_l$ ,  $A_r$  and  $A_h$  are shown schematically. See *Engineering Manual* for definition of thermal variables.

Figure 13. Examples of air-flow openings for an interior shade covering glass of height  $H$  and width  $W$ . Not to scale. (a) Horizontal section through shade with openings on the left and right sides (top view). (b) Vertical section through shade with openings at the top and bottom (side view). In (a) Left-Side Opening Multiplier =  $A_l/sH = \min(l/s, 1)$  and Right-Side Opening Multiplier =  $A_r/sH = \min(r/s, 1)$ . In (b) Top Opening Multiplier =  $A_{top}/sW = t/s$  and Bottom Opening Multiplier =  $A_{bot}/sW = b/s$ .

An IDF example:

```

  0.0;                              !- Air flow permeability
```

### 1.8.32 WindowMaterial:Blind

This object specifies the properties of a window blind consisting of flat, equally-spaced slats. Unlike window shades, which are modeled as perfect diffusers, window blinds have solar and visible transmission and reflection properties that strongly depend on slat angle and angle of incidence of solar radiation. There is an EnergyPlus Reference Data Set for WindowMaterial:Blind that contains properties of generic window blinds.

Blinds can be located on the inside of the window (“interior blinds”), on the outside of the window (“exterior blinds”), or between two layers of glass (“between-glass blinds”). When in place, the blind is assumed to cover all of the glazed part of the window, including dividers; it does not cover any of the window frame, if present. The plane of the blind is assumed to be parallel to the glazing. When the blind is retracted it is assumed to cover none of the window. The solar and

thermal effects of the blind's support strings, tapes or rods are ignored. Slat curvature, if present, is ignored.

There are two methods of assigning a blind to a window:

#### **1.8.32.1 Method 1:**

- 1) Define the construction of the window without the blind, the so-called "bare" construction.
- 2) Reference the bare construction in the FenestrationSurface:Detailed for the window.
- 3) Define the WindowMaterial:Blind.
- 4) Define a WindowProperty:ShadingControl for the window in which you (a) specify that this WindowMaterial:Blind is the window's shading device and (b) specify how the blind is controlled.

#### **1.8.32.2 Method 2:**

- 1) Define the Construction of the window without the blind, the so-called "bare" construction.
- 2) Reference the bare construction in the FenestrationSurface:Detailed for the window.
- 3) Define the WindowMaterial:Blind.
- 4) Define another Construction, called the "shaded construction," that includes the WindowMaterial:Blind.
- 5) Define a WindowProperty:ShadingControl for the window in which you (a) reference the shaded construction and (b) specify how the blind is controlled.

Note that WindowProperty:ShadingControl has to be used with either method, even if the blind is in place at all times. You will get an error message if you try to reference a construction with a blind directly from Window objects (FenestrationSurface:Detailed or Window).

Note also that WindowProperty:ShadingControl is used to determine not only when the blind is in place, but how its slat angle is controlled.

#### **1.8.32.3 Field: Name**

Name of the blind. It is referenced as a layer in a window construction (ref: Construction object) or as a "Material Name of Shading Device" in a WindowProperty:ShadingControl object.

#### **1.8.32.4 Field: Slat Orientation**

The choices are Horizontal and Vertical. "Horizontal" means the slats are parallel to the bottom of the window; this is the same as saying that the slats are parallel to the X-axis of the window. "Vertical" means the slats are parallel to Y-axis of the window.

#### **1.8.32.5 Field: Slat Width**

The width of the slat measured from edge to edge (m). See Figure 14.

#### **1.8.32.6 Field: Slat Separation**

The distance between the front of a slat and the back of the adjacent slat (m). See Figure 14.

#### **1.8.32.7 Field: Slat Thickness**

The distance between the faces of a slat (m). See Figure 14.

#### **1.8.32.8 Field: Slat Angle**

The angle (degrees) between the glazing outward normal and the slat outward normal, where the outward normal points away from the front face of the slat (degrees). See Figure 14.

If the WindowProperty:ShadingControl for the blind has Type of Slat Angle Control for Blinds = FixedSlatAngle, the slat angle is fixed at "Slat Angle."

If Type of Slat Angle Control for Blinds = BlockBeamSolar, the program automatically adjusts the slat angle so as just block beam solar radiation. In this case the value of "Slat Angle" is used only when the blind is in place and there is no beam solar radiation incident on the blind.

If Type of Slat Angle Control for Blinds = ScheduledSlatAngle, the slat angle is variable. In this case "Slat Angle" is not applicable and the field should be blank.

If Type of Slat Angle Control for Blinds = FixedSlatAngle and "Slat Angle" is less than the minimum or greater than the maximum allowed by Slat Width, Slat Separation and Slat Thickness, the slat angle will be reset to the corresponding minimum or maximum and a warning will be issued.

#### **1.8.32.9 Field: Slat Conductivity**

The thermal conductivity of the slat (W/m-K).

**1.8.32.10 Field: Slat Beam Solar Transmittance**

The beam solar transmittance of the slat, assumed to be independent of angle of incidence on the slat. Any transmitted beam radiation is assumed to be 100% diffuse (i.e., slats are translucent).

**1.8.32.11 Field: Front Side Slat Beam Solar Reflectance**

The beam solar reflectance of the front side of the slat, assumed to be independent of angle of incidence (matte finish). This means that slats with a large specularly-reflective component (shiny slats) are not well modeled.

**1.8.32.12 Field: Back Side Slat Beam Solar Reflectance**

The beam solar reflectance of the back side of the slat, assumed to be independent of angle of incidence (matte finish). This means that slats with a large specularly-reflective component (shiny slats) are not well modeled.

**1.8.32.13 Field: Slat Diffuse Solar Transmittance**

The slat transmittance for hemispherically diffuse solar radiation. This value should equal "Slat Beam Solar Transmittance."

**1.8.32.14 Field: Front Side Slat Diffuse Solar Reflectance**

The front-side slat reflectance for hemispherically diffuse solar radiation. This value should equal "Front Side Slat Beam Solar Reflectance."

**1.8.32.15 Field: Back Side Slat Diffuse Solar Reflectance**

The back-side slat reflectance for hemispherically diffuse solar radiation. This value should equal "Back Side Slat Beam Solar Reflectance."

**1.8.32.16 Field: Slat Beam Visible Transmittance**

The beam visible transmittance of the slat, assumed to be independent of angle of incidence on the slat. Any transmitted visible radiation is assumed to be 100% diffuse (i.e., slats are translucent).

**1.8.32.17 Field: Front Side Slat Beam Visible Reflectance**

The beam visible reflectance on the front side of the slat, assumed to be independent of angle of incidence (matte finish). This means that slats with a large specularly-reflective component (shiny slats) are not well modeled.

**1.8.32.18 Field: Back Side Slat Beam Visible Reflectance**

The beam visible reflectance on the front side of the slat, assumed to be independent of angle of incidence (matte finish). This means that slats with a large specularly-reflective component (shiny slats) are not well modeled.

**1.8.32.19 Field: Slat Diffuse Visible Transmittance**

The slat transmittance for hemispherically diffuse visible radiation. This value should equal "Slat Beam Visible Transmittance."

**1.8.32.20 Field: Front Side Slat Diffuse Visible Reflectance**

The front-side slat reflectance for hemispherically diffuse visible radiation. This value should equal "Front Side Slat Beam Visible Reflectance."

**1.8.32.21 Field: Back Side Slat Diffuse Visible Reflectance**

The back-side slat reflectance for hemispherically diffuse visible radiation. This value should equal "Back Side Slat Beam Visible Reflectance.."

**1.8.32.22 Field: Slat Infrared Hemispherical Transmittance**

The slat Infrared transmittance. It is zero for solid metallic, wooden or glass slats, but may be non-zero in some cases (e.g., thin plastic slats).

**1.8.32.23 Field: Front Side Slat Infrared Hemispherical Emissivity**

Front-side hemispherical emissivity of the slat. Approximately 0.9 for most materials. The most common exception is bare (unpainted) metal slats or slats finished with a metallic paint.

**1.8.32.24 Field: Back Side Slat Infrared Hemispherical Emissivity**

Back-side hemispherical emissivity of the slat. Approximately 0.9 for most materials. The most common exception is bare (unpainted) metal slats or slats finished

with a metallic paint.

#### 1.8.32.25 Field: Blind to Glass Distance

For interior and exterior blinds, the distance from the mid-plane of the blind to the adjacent glass (m). See Figure 14. Not used for between-glass blinds. As for window shades (ref: WindowMaterial:Shade) this distance is used in calculating the natural convective air flow between glass and blind that is produced by buoyancy effects.

#### 1.8.32.26 Opening Multipliers

The following opening multipliers are defined in the same way as for window shades (see WindowMaterial:Shade, Figure 12 and Figure 13). Note that, unlike window shades, there is no input for Air-Flow Permeability; this is automatically calculated by the program from slat angle, width and separation.

#### 1.8.32.27 Field: Blind Top Opening Multiplier

Defined as for Material:WindowShade.

#### 1.8.32.28 Field: Blind Bottom Opening Multiplier

Defined as for Material:WindowShade.

#### 1.8.32.29 Field: Blind Left-Side Opening Multiplier

Defined as for Material:WindowShade.

#### 1.8.32.30 Field: Blind Right-Side Opening Multiplier

Defined as for Material:WindowShade.

#### 1.8.32.31 Field: Minimum Slat Angle

The minimum allowed slat angle (degrees). Used only if WindowProperty:ShadingControl (for the window that incorporates this blind) varies the slat angle (i.e., the WindowProperty:ShadingControl has Type of Slat Angle Control for Blinds = ScheduledSlatAngle or BlockBeamSolar). In this case, if the program tries to select a slat angle less than Minimum Slat Angle it will be reset to Minimum Slat Angle. (Note that if the Minimum Slat Angle itself is less than the minimum allowed by Slat Width, Slat Separation and Slat Thickness, it will be reset to that minimum.)

#### 1.8.32.32 Field: Maximum Slat Angle

The maximum allowed slat angle (degrees). Used only if WindowProperty:ShadingControl (for the window that incorporates this blind) varies the slat angle (i.e., the WindowProperty:ShadingControl has Type of Slat Angle Control for Blinds = ScheduledSlatAngle or BlockBeamSolar). In this case, if the program tries to select a slat angle greater than Maximum Slat Angle the slat angle will be reset to Maximum Slat Angle. (Note that if the Maximum Slat Angle itself is greater than the maximum allowed by Slat Width, Slat Separation and Slat Thickness, it will be reset to that maximum.)

```

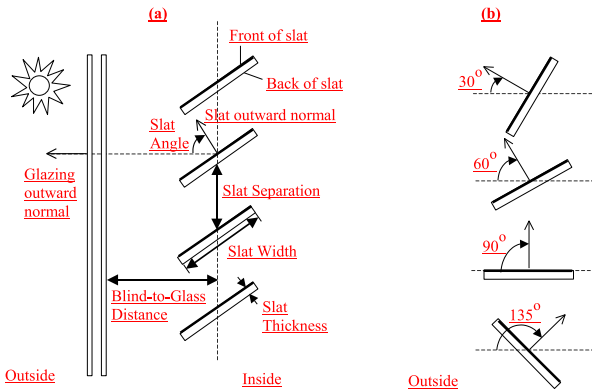

Figure 14. (a) Side view of a window blind with horizontal slats (or top view of blind with vertical slats) showing slat geometry. The front face of a slat is shown by a heavy line. The slat angle is defined as the angle between the glazing outward normal and the slat outward normal, where the outward normal points away from the front face of the slat. (b) Slat orientations for representative slat angles. The slat angle varies from  $0^\circ$ , when the front of the slat is parallel to the glazing and faces toward the outdoors, to  $90^\circ$ , when the slat is perpendicular to the glazing, to  $180^\circ$ , when the front of the slat is parallel to the glazing and faces toward the indoors. The minimum and maximum slat angles are determined by the slat thickness, width and separation.

### 1.8.33 WindowMaterial:ComplexShade

This input object is used to define shade layers used in the Construction:ComplexFenestrationState object.

#### 1.8.33.1 Field: Name

Unique name of the shading layer.

#### 1.8.33.2 Field: Shading Layer Type

The type of shading layer. The options are:

- Venetian – for modeling venetian blinds
- Woven – for modeling shading systems with a regular weave
- Perforated – for modeling perforated screens
- BSDF – for modeling shades whose properties are represented by a BSDF file
- OtherShadingType – for modeling shading systems which do not belong to the any of the previous group

#### 1.8.33.3 Field: Thickness

The thickness (m) of the shading layer. This value is ignored for ShadingLayerType = Venetian, because the program will calculate the thickness based on the slat angle. This value is needed for ShadingLayerType = Woven and Perforated

#### 1.8.33.4 Field: Conductivity

The conductivity (W/mK) of the shading layer material. Default: 1.0

- Venetian – the conductivity of the venetian blind slat material
- Woven – the conductivity of the woven shade material (such as the thread for a fabric shade)
- Perforated – for modeling perforated screens
- BSDF – for modeling shades whose properties are represented by a BSDF file
- OtherShadingType – for modeling shading systems which do not belong to the any of the previous group

#### 1.8.33.5 Field: IR Transmittance

The IR transmittance of the shading layer. Minimum value: 0. Maximum value: 1. Default: 0.

#### 1.8.33.6 Field: Front Emissivity

The front emissivity of the shading layer. Minimum value: 0. Maximum value: 1. Default: 0.90.

### 1.8.33.7 Field: Back Emissivity

The back emissivity of the shading layer. Minimum value: 0. Maximum value: 1. Default: 0.90.

### 1.8.33.8 Field: Top Opening Multiplier

The top opening multiplier value will depend on the location of the shading device within the glazing system. There are several possible scenarios which can occur and they can be divided into two groups:

#### Shading device on the indoor/outdoor side of the window

In this case the opening multiplier is calculated as the smallest distance between the shading device and the frame ( $d_{top}$ ), divided by the gap width ( $S$ ). There are three possible cases for the position of a shading device on the indoor/outdoor side (see Figure 15).

Figure 15. Three cases for the  $D_{top}$  calculation for an indoor/outdoor shade: Case a) A shading device between the frame; Case b) A shading device outside the frame, covering the frame; Case c) a shading device outside the frame, not covering the frame.

In the case where the distance between the frame and the shading device is bigger than the gap width, the  $d_{top}$  multiplier is equal to one. Therefore, the calculation of the  $D_{top}$  opening multiplier is:

$$A_{top} = \min(d_{top}/S, 1)$$

#### Shading device between glass layers

In this case the opening multiplier is calculated as the smallest distance between the shading device and the frame or spacer ( $d_p$ ), divided by the smaller gap width (the minimum of ( $S_1$  and  $S_2$ )).

Figure 16. Calculation of  $D_{top}$  for a shading device between glass layers

The  $D_{top}$  opening multiplier for a between glass shade is calculated as:

$$A_{top} = \min(d_{top}/S_{min}, 1)$$

Where

$$S_{min} = \min(S_1, S_2)$$

#### 1.8.33.9 Field: Bottom Opening Multiplier

The bottom opening multiplier ( $d_{bot}$ ) is calculated in the same way as the top opening multiplier, with the rules applied to the bottom of the shading device.

#### 1.8.33.10 Field: Left Side Opening Multiplier

The left side opening multiplier ( $d_{left}$ ) is calculated in the same way as the top opening multiplier, with the rules applied to the left side of the shading device.

#### 1.8.33.11 Field: Right Side Opening Multiplier

The right side opening multiplier ( $d_{right}$ ) is calculated in the same way as the top opening multiplier, with the rules applied to the right side of the shading device.

#### 1.8.33.12 Field: Front Opening Multiplier

The fraction of glazing system area that is open on the front of the shading layer (see Figure 17). This fraction is calculated as follows:  $A_{front} / (W * H)$ , where  $A_{front}$  = Area of the front of the glazing system that is not covered by the shading system,  $W$  = the width of the glazing system (IGU) and  $H$  is height of the glazing system (IGU).

Figure 17. Front view of shading layer openings.

**1.8.33.13 Field: Slat Width**

The width (m) of the venetian slats. Used only for ShadingLayerType = Venetian.

**1.8.33.14 Field: Slat Spacing**

The distance (m) between front sides of the venetian slats. Used only for ShadingLayerType = Venetian.

**1.8.33.15 Field: Slat Thickness**

The thickness (m) of the venetian slats. Used only for ShadingLayerType = Venetian.

**1.8.33.16 Field: Slat Angle**

The slat tilt angle (degrees) of the venetian slats. Used only for ShadingLayerType = Venetian. Range of slat angle is from -90 to 90 degrees.

**1.8.33.17 Field: Slat Conductivity**

The conductivity (W/mK) of the venetian slats. Used only for ShadingLayerType = Venetian.

**1.8.33.18 Field: Slat Curve**

The curvature radius (m) of the venetian slats. Setting this value to zero means there is no curvature in the slat (it is flat), while a non-zero value is the radius of the slat curve. This value cannot be smaller than Slat Width / 2. Used only for ShadingLayerType = Venetian.

Figure 18. Side view of horizontal venetian blind slats or top view of blinds with vertical slats. Front face of slats is marked with red line.

An IDF example for ShadingLayerType = Venetian

### 1.8.34 WindowMaterial:Screen

This object specifies the properties of exterior window screen materials. The window screen model assumes the screen is made up of intersecting orthogonally-crossed cylinders. The surface of the cylinders is assumed to be diffusely reflecting, having the optical properties of a Lambertian surface.

The beam solar radiation transmitted through a window screen varies with sun angle and is made up of two distinct elements: a direct beam component and a reflected beam component. The direct beam transmittance component is modeled using the geometry of the screen material and the incident angle of the sun to account for shadowing of the window by the screen material. The reflected beam component is an empirical model that accounts for the inward reflection of solar beam off the screen material surface. This component is both highly directional and small in magnitude compared to the direct beam transmittance component (except at higher incident angles, for which case the magnitude of the direct beam component is small or zero and the reflected beam component, though small in absolute terms can be many times larger than the direct beam component). For this reason, the reflected beam transmittance component calculated by the model can be a. disregarded, b. treated as an additive component to direct beam transmittance (and in the same direction), or c. treated as hemispherically-diffuse transmittance based on a user input to the model.

Figure 19. Direct beam and reflected beam transmittance components

The window screen “assembly” properties of overall beam solar reflectance and absorptance (including the screen material ‘cylinders’ and open area) also change with sun angle and are calculated based on the values of the beam solar transmittance components (direct and reflected components described above) and the physical properties of the screen material (i.e., screen material diameter, spacing, and reflectance).

Transmittance, reflectance, and absorptance of diffuse solar radiation are considered constant values and apply to both the front and back surfaces of the screen. These properties are calculated by the model as an average value by integrating the screen’s beam solar properties over a quarter hemisphere of incident radiation. Long-wave emissivity is also assumed to be the same for both sides of the screen.

There is an EnergyPlus Reference Data Set for WindowMaterial:Screen that contains properties for generic window screens. Window screens of this type can only be used on the outside surface of the window (“exterior screens”). When in place, the screen is assumed to cover all of the glazed part of the window,

including dividers; it does not cover any of the window frame, if present. The plane of the screen is assumed to be parallel to the glazing.

WindowMaterial:Screen can be used to model wire mesh insect screens where the solar and visible transmission and reflection properties vary with the angle of incidence of solar radiation. For diffusing materials such as drapery and translucent roller shades it is better to use the WindowMaterial:Shade object. For slat-type shading devices like Venetian blinds, which have solar and visible transmission and reflection properties that strongly depend on slat angle and angle of incidence of solar radiation, it is better to use WindowMaterial:Blind.

There are two methods of assigning a screen to a window:

#### 1.8.34.1 Method 1:

- 1) Define the construction of the window without the screen, the so-called “bare” construction.
- 2) Reference the bare construction in the FenestrationSurface:Detailed for the window.
- 3) Define the WindowMaterial:Screen object.
- 4) Define a WindowProperty:ShadingControl for the window in which you (a) specify that this Material:WindowScreen is the window’s shading device, and (b) specify how the screen is controlled.

#### 1.8.34.2 Method 2:

- 1) Define the Construction of the window without the screen, the so-called “bare” construction.
- 2) Reference the bare construction in the FenestrationSurface:Detailed for the window.
- 3) Define the WindowMaterial:Screen object.
- 4) Define another Construction, called the “shaded construction,” that includes the WindowMaterial:Screen.
- 5) Define a WindowProperty:ShadingControl for the window in which you (a) reference the shaded construction, and (b) specify how the screen is controlled.

Note that WindowProperty:ShadingControl has to be used with either method, even if the screen is in place at all times. You will get an error message if you try to reference a shaded construction directly from a FenestrationSurface:Detailed object.

#### 1.8.34.3 Field: Name

Enter a unique name for the screen. This name is referenced as an outside layer in a window construction.

#### 1.8.34.4 Field: Reflected Beam Transmittance Accounting Method

This input specifies the method used to account for screen-reflected beam solar radiation that is transmitted through the window screen (as opposed to being reflected back outside the building). Since this inward reflecting beam solar is highly directional and is not modeled in the direction of the actual reflection, the user is given the option of how to account for the directionality of this component of beam solar transmittance. Valid choices are DoNotModel, ModelAsDirectBeam (i.e., model as an additive component to direct solar beam and in the same direction), or ModelAsDiffuse (i.e., model as hemispherically-diffuse radiation). The default value is ModelAsDiffuse.

#### 1.8.34.5 Field: Diffuse Solar Reflectance

This input specifies the solar reflectance (beam-to-diffuse) of the screen material itself (not the effective value for the overall screen “assembly” including open spaces between the screen material). The outgoing diffuse radiation is assumed to be Lambertian (distributed angularly according to Lambert’s cosine law). The solar reflectance is assumed to be the same for both sides of the screen. This value must be from 0 to less than 1.0. In the absence of better information, the input value for diffuse solar reflectance should match the input value for diffuse visible reflectance.

#### 1.8.34.6 Field: Diffuse Visible Reflectance

This input specifies the visible reflectance (beam-to-diffuse) of the screen material itself (not the effective value for the overall screen “assembly” including open spaces between the screen material) averaged over the solar spectrum and weighted by the response of the human eye. The outgoing diffuse radiation is assumed to be Lambertian (distributed angularly according to Lambert’s cosine law). The visible reflectance is assumed to be the same for both sides of the screen. This value must be from 0 to less than 1.0.

If diffuse visible reflectance for the screen material is not available, then the following guidelines can be used to estimate this value:

- Dark-colored screen (e.g., charcoal): 0.08 – 0.10
- Medium-colored screen (e.g., gray): 0.20 – 0.25
- Light-colored screen (e.g., bright aluminum): 0.60 – 0.65

Commercially-available gray scale or grayscale reflecting chart references can be purchased for improved accuracy in estimating visible reflectance (by visual

comparison of screen reflected brightness with that of various known-reflectance portions of the grayscale).

#### 1.8.34.7 Field: Thermal Hemispherical Emissivity

Long-wave emissivity  $\epsilon$  of the screen material itself (not the effective value for the overall screen “assembly” including open spaces between the screen material). The emissivity is assumed to be the same for both sides of the screen.

For most non-metallic materials,  $\epsilon$  is about 0.9. For metallic materials,  $\epsilon$  is dependent on material, its surface condition, and temperature. Typical values for metallic materials range from 0.05 – 0.1 with lower values representing a more finished surface (e.g. low oxidation, polished surface). Material emissivities may be found in Table 5 from the 2005 ASHRAE Handbook of Fundamentals, page 3.9. The value for this input field must be between 0 and 1, with a default value of 0.9 if this field is left blank.

#### 1.8.34.8 Field: Conductivity

Screen material conductivity (W/m-K). This input value must be greater than 0. The default value is 221 W/m-K (aluminum).

#### 1.8.34.9 Field: Screen Material Spacing

The spacing,  $S$ , of the screen material (m) is the distance from the center of one strand of screen to the center of the adjacent one. The spacing of the screen material is assumed to be the same in both directions (e.g., vertical and horizontal). This input value must be greater than the non-zero screen material diameter. If the spacing is different in the two directions, use the average of the two values.

Figure 20. Screen Material Spacing and Diameter

#### 1.8.34.10 Field: Screen Material Diameter

The diameter,  $D$ , of individual strands or wires of the screen material (m). The screen material diameter is assumed to be the same in both directions (e.g., vertical and horizontal). This input value must be greater than 0 and less than the screen material spacing. If the diameter is different in the two directions, use the average of the two values.

#### 1.8.34.11 Field: Screen to Glass Distance

Distance from the window screen to the adjacent glass surface (m). If the screen is not flat, the average screen to glass distance should be used. The screen-to-glass distance is used in calculating the natural convective air flow between the glass and the screen produced by buoyancy effects. This input value must be from 0.001 m to 1 m, with a default value of 0.025 m if this field is left blank.

#### 1.8.34.12 Field: Top Opening Multiplier

Effective area for air flow at the top of the screen divided by the horizontal area between the glass and screen (see the same field for the Material:WindowShade object for additional description). The opening multiplier fields can be used to simulate a shading material that is offset from the window frame. Since window screens are typically installed against the window frame, the default value is equal to 0. This input value can range from 0 to 1.

#### 1.8.34.13 Field: Bottom Opening Multiplier

Effective area for air flow at the bottom of the screen divided the horizontal area between the glass and screen (see the same field for the Material:WindowShade object for additional description). The opening multiplier fields can be used to simulate a shading material that is offset from the window frame. Since window screens are typically installed against the window frame, the default value is equal to 0. This input value can range from 0 to 1.

#### 1.8.34.14 Field: Left-Side Opening Multiplier

Effective area for air flow at the left side of the screen divided the vertical area between the glass and screen (see the same field for the Material:WindowShade object for additional description). The opening multiplier fields can be used to simulate a shading material that is offset from the window frame. Since window screens are typically installed against the window frame, the default value is equal to 0. This input value can range from 0 to 1.

#### 1.8.34.15 Field: Right-Side Opening Multiplier

Effective area for air flow at the right side of the screen divided the vertical area between the glass and screen (see the same field for the Material:WindowShade object for additional description). The opening multiplier fields can be used to simulate a shading material that is offset from the window frame. Since window screens are typically installed against the window frame, the default value is equal to 0. This input value can range from 0 to 1.

#### 1.8.34.16 Field: Angle of Resolution for Screen Transmittance Output Map

Angle of resolution, in degrees, for the overall screen beam transmittance (direct and reflected) output map. The comma-separated variable file eplusscreen.csv (Ref. OutputDetailsandExamples.pdf) will contain the direct beam and reflected beam solar radiation that is transmitted through the window screen as a function of incident sun angle (0 to 90 degrees relative solar azimuth and 0 to 90 degrees relative solar altitude) in sun angle increments specified by this input field. The default value is 0, which means no transmittance map is generated. Other valid choice inputs are 1, 2, 3 and 5 degrees.

An IDF example for this object, along with Construction and WindowProperty:ShadingControl objects, is shown below:

#### 1.8.35 WindowMaterial:Shade:EquivalentLayer

This object specifies the properties of Equivalent Layer window shade (roller blind) materials. Shades are considered to be thin, flat and perfect diffusers (all transmitted and reflected radiation is hemispherically-diffuse). However, shades can have beam-beam transmittance by virtue of their material openness. The beam-beam transmittance is assumed to be the same for both sides of the shade and is the same as the openness area fraction. Beam-diffuse transmittance and reflectance, and emissivity properties can be different for front and back side of the shade. Window shades can be placed on the inside of the window, on the outside of the window, or between glass layers. WindowMaterial:Shade:EquivalentLayer is used for roller blinds. The off-normal solar property calculation of shades (roller blind) is based on a set of correlations developed from measurement of samples of commercially produced roller blind material with openness fraction less than 0.14. The model is not intended for materials with unusually high values of openness and should be limited to a maximum openness fraction of 0.20. The visible spectrum solar properties input fields are not used currently hence can be left blank.

##### 1.8.35.1 Field: Name

Name of the shade. It is referenced as an inside, inbetween or outside layer in an equivalent layer window construction.

##### 1.8.35.2 Field: Shade Beam-Beam Solar Transmittance

This value is the beam-beam transmittance of the shade at normal incidence and it is the same as the openness area fraction of the shade material. Assumed to be the same for front and back sides of the roller blinds. The minimum value is 0.0 and maximum value is less than 1.0. The default value is 0.0. For most common shade materials (e.g. Roller Blinds) the material openness fraction doesn't exceed 0.20.

##### 1.8.35.3 Field: Front Side Shade Beam-Diffuse Solar Transmittance

This value is the front side beam-diffuse transmittance of the shade material at normal incidence averaged over the entire spectrum of solar radiation. The minimum value is 0.0 and maximum value is less than 1.0. The default value is 0.0.

#### 1.8.35.4 Field: Back Side Shade Beam-Diffuse Solar Transmittance

This value is the back side beam-diffuse transmittance of the shade material at normal incidence averaged over the entire spectrum of solar radiation. The minimum value is 0.0 and maximum value is less than 1.0. The default value is 0.0.

#### 1.8.35.5 Field: Front Side Shade Beam-Diffuse Solar Reflectance

This value is the front side beam-diffuse reflectance of the shade material at normal incidence averaged over the entire spectrum of solar radiation. The minimum value is 0.0 and maximum value is less than 1.0.

#### 1.8.35.6 Field: Back Side Shade Beam-Diffuse Solar Reflectance

This value is the back side beam-diffuse reflectance of the shade material at normal incidence averaged over the entire spectrum of solar radiation. The minimum value is 0.0 and maximum value is less than 1.0.

#### 1.8.35.7 Field: Shade Beam-Beam Visible Transmittance

This value is the beam-beam transmittance at normal incidence averaged over the visible spectrum of solar radiation. Assumed to be the same for front and back sides. The minimum value is 0.0 and maximum value is less than 1.0. Currently this input field is not used.

#### 1.8.35.8 Field: Shade Beam-Diffuse Visible Transmittance

This value is the beam-diffuse transmittance at normal incidence averaged over the visible spectrum of solar radiation. Assumed to be the same for front and back sides. The minimum value is 0.0 and maximum value is less than 1.0. Currently this input field is not used.

#### 1.8.35.9 Field: Shade Beam-Diffuse Visible Reflectance

This value is the beam-diffuse reflectance at normal incidence averaged over the visible spectrum of solar radiation. Assumed to be the same for front and back sides. The minimum value is 0.0 and maximum value is less than 1.0. Currently this input field is not used.

#### 1.8.35.10 Field: Shade Material Infrared Transmittance

This value is the long-wave transmittance of the shade material and assumed to be the same for front and back sides of the shade. The minimum value is 0.0 and maximum value is less than 1.0. Default value is 0.05.

#### 1.8.35.11 Field: Front Side Shade Material Infrared Emissivity

This value is the front side long-wave hemispherical emissivity of shade material. The minimum value is 0.0 and maximum value is less than 1.0. Default value is 0.91. The front side effective emissivity of the shade layer is calculated using this value and the material openness specified above.

#### 1.8.35.12 Field: Back Side Shade Material Infrared Emissivity

This value is the back side long-wave hemispherical emissivity of shade material. The minimum value is 0.0 and maximum value is less than 1.0. Default value is 0.91. The back side effective emissivity of the shade is calculated using this value and the material openness specified above.

An IDF example for this object is shown below:

#### 1.8.36 WindowMaterial:Drape:EquivalentLayer

Specifies the optical and thermal properties of equivalent layer window drape fabric materials.

Drapery fabric shades are commonly placed on the the inside of the window. The long-wave (infrared) properties for commonly used drapery fabrics are assumed to be the same on both sides but different values can be specified when required. Drape fabric shade layers are considered to be perfect diffusers (reflected radiation is hemispherically-diffuse independent of angle of incidence). Unpleated drape fabric is treated as thin and flat layer. The off-normal optical properties of drapery fabric is determined from user specified optical properties at normal incidence using empirical correlations. Pleated drape fabric requires entering the pleated section average width and length as shown in Figure 21. For pleated drapes the effective beam-beam and beam-diffuse solar properties are

determined by tracking both radiation components, for a given incident angle solar radiation, through various interactions with a fabric pleated in a rectangular geometry shown in Figure 21. The solar properties of the two different pleat facets are evaluated on the basis of the local solar incidence angle. Therefore, the effective layer properties are influenced not just by horizontal solar profile angle, but also by incidence angle. The correlations used for drape fabrics optical property calculations require that the solar absorptance of the fabric, at normal incidence, is not less than 1%.

Figure 21. Geometry used for Pleated Drapery Analysis

**1.8.36.1 Field: Name**

Name of the drape fabric shade layer. It is referenced as an inside, in between or outside layer in an equivalent layer window construction.

**1.8.36.2 Field: Drape Beam-Beam Solar Transmittance**

This value is the drape fabric beam-beam transmittance at normal incidence, and it is the same as the drape fabric openness area fraction. Assumed to be the same for front and back sides of the drape fabric layer. The minimum value is 0.0 and maximum value is less than 1.0. For most drape fabric materials the maximum fabric openness fraction do not exceed 0.2. The default value is 0.0.

**1.8.36.3 Field: Front Side Drape Beam-Diffuse Solar Transmittance**

This value is the front side beam-diffuse solar transmittance of the drape fabric material at normal incidence averaged over the entire spectrum of solar radiation. The minimum value is 0.0 and maximum value is less than 1.0.

**1.8.36.4 Field: Back Side Drape Beam-Diffuse Solar Transmittance**

This value is the back side beam-diffuse solar transmittance of the drape fabric material at normal incidence averaged over the entire spectrum of solar radiation. The minimum value is 0.0 and maximum value is less than 1.0.

**1.8.36.5 Field: Front Side Drape Beam-Diffuse Solar Reflectance**

This value is the front side beam-diffuse solar reflectance of the drape fabric material at normal incidence averaged over the entire spectrum of solar radiation. The minimum value is 0.0 and maximum value is less than 1.0.

**1.8.36.6 Field: Back Side Drape Beam-Diffuse Solar Reflectance**

This value is the back side beam-diffuse solar reflectance of the drape fabric material at normal incidence averaged over the entire spectrum of solar radiation. The minimum value is 0.0 and maximum value is less than 1.0.

**1.8.36.7 Field: Drape Beam-Beam Visible Transmittance**

This value is the drape fabric beam-beam visible transmittance at normal incidence averaged over the visible spectrum range of solar radiation. Assumed to be the same for front and back sides of the drape fabric layer. The minimum value is 0.0 and maximum value is less than 1.0. The default value is 0.0. This input field is not used currently.

**1.8.36.8 Field: Front Side Drape Beam-Diffuse Visible Reflectance**

This value is the front side drape fabric beam-diffuse visible reflectance at normal incidence averaged over the visible spectrum range of solar radiation. Assumed to be the same for front and back sides of the drape. The minimum value is 0.0 and maximum value is less than 1.0. The default value is 0.0. This input field is not used currently.

**1.8.36.9 Field: Back Side Drape Diffuse-Diffuse Visible Reflectance**

This value is the back side drape fabric diffuse-diffuse visible reflectance at normal incidence averaged over the visible spectrum range of solar radiation. Assumed to be the same for front and back sides of the drape. The minimum value is 0.0 and maximum value is less than 1.0. The default value is 0.0. This input field is not used currently.

**1.8.36.10 Field: Drape Material Infrared Transmittance**

This value is the long-wave hemispherical transmittance of the fabric material at zero fabric openness fraction. Assumed to be the same for front and back sides of the drape fabric material layer. The minimum value is 0.0 and maximum value is less than 1.0. The default value is 0.05.

**1.8.36.11 Field: Front Side Drape Material Infrared Emissivity**

This value is the front side long-wave hemispherical emissivity of fabric material at zero shade openness. The minimum value is 0.0 and maximum value is less than 1.0. the default value is 0.87. The front side effective emissivity of the drape fabric layer is calculated using this value and the fabric openness area fraction specified above.

**1.8.36.12 Field: Back Side Drape Material Infrared Emissivity**

This value is the back side long-wave hemispherical emissivity of fabric material at zero fabric openness fraction. The minimum value is 0.0 and maximum value is less than 1.0. The default value is 0.87. The back side effective emissivity of the drape fabric layer is calculated using this value and the fabric openness area fraction specified above.

**1.8.36.13 Field: Width of Pleated Fabric**

This value is the width of the pleated section of the draped fabric, w(m). If the drape fabric is flat (unpleated), then the pleated section width is set to zero. The default value is 0.0, i.e., assumes flat drape fabric.

**1.8.36.14 Field: Length of Pleated Fabric**

This value is the length of the pleated section of the draped fabric, s(m). If the drape fabric is flat (unpleated), then the pleated section length is set to zero. The default value is 0.0, i.e., assumes flat drape fabric.

An IDF example for this object is shown below:

```

**1.8.37 WindowMaterial:Blind:EquivalentLayer**

This object specifies the properties of an Equivalent Layer window blind consisting of thin and equally-spaced slats. The the model assumes that slats are flat and thin, and applies correction for the slat curvature effect based on the user specified slat crwon. Slats are assumed to transmit and reflect diffusely. The effective shortwave optical and longwave optical properties of venetian blind layer is estimated analytically. The Equivalent Layer blind model requires optical

properties and geometry of the slats shown

Figure 22. Geometry and Properties used for venetian blind analysis

. Likewise, effective longwave properties are obtained for the layer knowing longwave properties of the slats.

Figure 22. Geometry and Properties used for venetian blind analysis

The input data required to characterize a venetian blind are: front and back side reflectance and transmittance of the slat, geometry (Slat width,  $w$ , slat spacing,  $s$ , slat crown,  $c$ , and slat angle,  $f$ , and long wave emittance and transmittance of the slat. Blinds can be located on the inside of the window, on the outside of the window, or between two layers of glass. The blind is assumed to cover all of the glazed part of the window.

#### **1.8.37.1 Field: Name**

Name of the venetian blind. It is referenced as an inside, outside or in between layers in an equivalent layer window construction.

#### **1.8.37.2 Field: Slat Orientation**

The choices are Horizontal and Vertical. "Horizontal" means the slats are parallel to the bottom of the window; this is the same as saying that the slats are parallel to the X-axis of the window. "Vertical" means the slats are parallel to Y-axis of the window. The default is "Horizontal".

#### **1.8.37.3 Field: Slat Width**

This value is the width of the slat measured from edge to edge (m). The default value is 0.0254.

#### **1.8.37.4 Field: Slat Separation**

The distance between the front of a slat and the back of the adjacent slat (m). The default value is 0.025. The slat separation should not be greater than the slat width.

#### **1.8.37.5 Field: Slat Crown**

The perpendicular length between the slat cord and the curve (m).  $Crown = 0.0625 \times \text{"Slat width"}$ . Slat is assumed to be rectangular in cross section and flat. The crown accounts for curvature of the slat. The minimum value is 0.0, and the default value is 0.0015m.

#### **1.8.37.6 Field: Slat Angle**

The angle (degrees) between the glazing outward normal and the slat outward normal, where the outward normal points away from the front face of the slat (degrees). If the "Slat Angle Control" input field below specified is "FixedSlatAngle", then the slat angle is fixed at "Slat Angle" value entered. Minimum value is zero, and the maximum value allowed is 180.0 degrees. The default value is 45 degrees.

#### **1.8.37.7 Field: Front Side Slat Beam-Diffuse Solar Transmittance**

This value is the slat front side beam-diffuse solar transmittance at normal incidence averaged over the entire spectrum of solar radiation. Any transmitted beam radiation is assumed to be 100% diffuse (i.e., slats are translucent). Minimum value is 0.0, and the maximum value is less than 1.0. The default value is 0.0.

#### **1.8.37.8 Field: Back Side Slat Beam-Diffuse Solar Transmittance**

This value is the slat back side beam-diffuse solar transmittance at normal incidence averaged over the entire spectrum of solar radiation. Any transmitted beam radiation is assumed to be 100% diffuse (i.e., slats are translucent). Minimum value is 0.0, and the maximum value is less than 1.0. The default value is 0.0.

#### **1.8.37.9 Field: Front Side Slat Beam-Diffuse Solar Reflectance**

This value is slat front side beam-diffuse solar reflectance at normal incidence averaged over the entire spectrum of solar radiation. All the reflected component is assumed to be diffuse. Minimum value is 0.0, and the maximum value is less than 1.0.

#### **1.8.37.10 Field: Back Side Slat Beam-Diffuse Solar Reflectance**

This value is the slat back side beam-diffuse solar reflectance at normal incidence averaged over the entire spectrum of solar radiation. All the reflected component is assumed to be diffuse. Minimum value is 0.0, and the maximum value is less than 1.0.

#### **1.8.37.11 Field: Front Side Slat Beam-Diffuse Visible Solar Transmittance**

This value is the slat front side beam-diffuse visible transmittance at normal incidence averaged over the visible spectrum range of solar radiation. Any transmitted beam radiation is assumed to be 100% diffuse (i.e., slats are translucent). Minimum value is 0.0, and the maximum value is less than 1.0. The default value is 0.0.

#### **1.8.37.12 Field: Back Side Slat Beam-Diffuse Visible Solar Transmittance**

This value is the slat back side beam-diffuse visible transmittance at normal incidence averaged the visible spectrum range of solar radiation. Any transmitted beam radiation is assumed to be 100% diffuse (i.e., slats are translucent). Minimum value is 0.0, and the maximum value is less than 1.0. The default value is 0.0.

#### **1.8.37.13 Field: Front Side Slat Beam-Diffuse Visible Solar Reflectance**

This value is the slat front side beam-diffuse visible reflectance at normal incidence averaged over the visible spectrum range of solar radiation. All the reflected component is assumed to be diffuse. Minimum value is 0.0, and the maximum value is less than 1.0

#### **1.8.37.14 Field: Back Side Slat Beam-Diffuse Visible Solar Reflectance**

This value is the slat back side beam-diffuse visible reflectance at normal incidence averaged over the visible spectrum range of solar radiation. All the reflected component is assumed to be diffuse. Minimum value is 0.0, and the maximum value is less than 1.0

#### **1.8.37.15 Field: Slat Diffuse-Diffuse Solar Transmittance**

This value is the slat diffuse-diffuse solar transmittance for hemispherically diffuse solar radiation. This value is the same for front and back side of the slat. Minimum value is 0.0, and the maximum value is less than 1.0.

#### **1.8.37.16 Field: Front Side Slat Diffuse-Diffuse Solar Reflectance**

This value is the slat front side diffuse-diffuse solar reflectance for hemispherically diffuse solar radiation. Minimum value is 0.0, and the maximum value is less than 1.0.

#### **1.8.37.17 Field: Back Side Slat Diffuse-Diffuse Solar Reflectance**

This value is the slat back side diffuse-diffuse solar reflectance for hemispherically diffuse solar radiation. Minimum value is 0.0, and the maximum value is less than 1.0.

#### **1.8.37.18 Field: Slat Diffuse-Diffuse Visible Transmittance**

This value is the slat diffuse-diffuse visible transmittance for hemispherically diffuse visible spectrum range of solar radiation. This value is the same for front and back side of the slat. Minimum value is 0.0, and the maximum value is less than 1.0. This input field is not used currently.

#### **1.8.37.19 Field: Front Side Slat Diffuse-Diffuse Visible Reflectance**

This value is the slat front side diffuse-diffuse visible reflectance for hemispherically diffuse visible spectrum range of solar radiation. Minimum value is 0.0, and the maximum value is less than 1.0. This input field is not used currently.

#### **1.8.37.20 Field: Back Side Slat Diffuse-Diffuse Visible Reflectance**

This value is the slat back side diffuse-diffuse visible reflectance for hemispherically diffuse visible spectrum range of solar radiation. Minimum value is 0.0, and the maximum value is less than 1.0. This input field is not used currently.

#### **1.8.37.21 Field: Slat Infrared Transmittance**

This value is the long-wave hemispherical transmittance of the slat material. Assumed to be the same for both sides of the slat. The minimum value is 0.0, the maximum value is less than 1.0. The default value is 0.0.

#### **1.8.37.22 Field: Front Side Slat Infrared Emissivity**

This value is the front side long-wave hemispherical emissivity of the slat material. The minimum value is 0.0, the maximum value is less than 1.0. The default value is 0.9.

#### **1.8.37.23 Field: Back Side Slat Infrared Emissivity**

This value is the back side long-wave hemispherical emissivity of the slat material. The minimum value is 0.0, the maximum value is less than 1.0. The default value is 0.9.

#### **1.8.37.24 Field: Slat Angle Control**

This input field is used only if slat angle control is desired. The three key choice inputs allowed are "FixedSlatAngle", "MaximizeSolar", and "BlockBeamSolar". The default value is "FixedSlatAngle". If Type of Slat Angle Control for Blinds = MaximizeSolar the slat angle is adjusted to maximize solar gain. If Type of Slat Angle Control for Blinds = BlockBeamSolar, the slat angle is adjusted to maximize visibility while eliminating beam solar radiation. If Type of Slat Angle Control for Blinds = FixedSlatAngle, then the model uses a fixed slat angle specified above.

### 1.8.38 WindowMaterial:Screen:EquivalentLayer

This object specifies the optical and thermal properties of exterior screen materials for Equivalent Layer Window. Can only be placed on the exterior side of window construction. The window screen model assumes the screen is made up of intersecting orthogonally-crossed cylinders. The surface of the cylinders is assumed to be diffusely reflecting. The beam solar radiation transmitted through an equivalent Layer window screen varies with sun angle and is made up of two distinct elements: a beam-beam component and a beam-diffuse component. The beam-beam transmittance component is calculated using screen openness area fraction determined from the geometry of the screen and the incident angle of the sun. Empirical correlations are used to obtain the effective off-normal solar and longwave properties of insect screens. Insect screen geometry is shown in Figure 23. The calculation of effective solar properties requires a set of properties measured at normal incidence.

Figure 23. Geometry used for insect screen analysis

The formulation of the model, assumption and correlations used to calculate effective solar and longwave properties of insect screens are described in the Engineering Reference.

#### 1.8.38.1 Field: Name

Name of the insect screen. It is referenced as an outside layer in an equivalent layer window construction.

#### 1.8.38.2 Field: Screen Beam-Beam Solar Transmittance

This value is the beam-beam transmittance of the screen material at normal incidence. This value is the same as the screen openness area fraction. This value can be autocalculated from the wire spacing and wire diameter. It is the same for both sides of the screen. The minimum value is 0.0, and maximum value is less than 1.0.

#### 1.8.38.3 Field: Screen Beam-Diffuse Solar Transmittance

This value is the beam-diffuse solar transmittance of the screen material at normal incidence averaged over the entire spectrum of solar radiation. Assumed to be the same for both sides of the screen. The minimum value is 0.0, and the maximum value is less than 1.0.

#### 1.8.38.4 Field: Screen Beam-Diffuse Solar Reflectance

This value is the beam-diffuse solar reflectance of the screen material at normal incidence averaged over the entire spectrum of solar radiation. Assumed to be the same for both sides of the screen. The minimum value is 0.0, and the maximum value is less than 1.0.

#### 1.8.38.5 Field: Screen Beam-Beam Visible Transmittance

This value is the beam-beam visible transmittance of the screen material at normal incidence averaged over the visible spectrum range of solar radiation. Assumed to be the same for both sides of the screen. The minimum value is 0.0, and maximum value is less than 1.0. This input field is not used currently.

#### 1.8.38.6 Field: Screen Beam-Diffuse Visible Transmittance

This value is the beam-diffuse visible reflectance of the screen material at normal incidence averaged over the visible spectrum range of solar radiation. Assumed to be the same for both sides of the screen. The minimum value is 0.0, and the maximum value is less than 1.0. This input input field is not used currently.

#### 1.8.38.7 Field: Screen Beam-Diffuse Visible Reflectance

This value is the beam-diffuse visible reflectance of the screen material at normal incidence averaged over the visible spectrum range of solar radiation. Assumed to be the same for both sides of the screen. The minimum value is 0.0, and the maximum value is less than 1.0. This input input field is not used currently.

#### 1.8.38.8 Field: Screen Infrared Transmittance

This value is the long-wave hemispherical transmittance of the the screen material. Assumed to be the same for both sides of the screen material. The minimum value is 0.0, the maximum value is less than 1.0. The default value is 0.02

#### 1.8.38.9 Field: Screen Infrared Emissivity

This value is the long-wave hemispherical emissivity of the screen material. Assumed to be the same for both sides of the screen material. The minimum value is 0.0, the maximum value is less than 1.0. The default value is 0.93.

#### 1.8.38.10 Field: Screen Wire Spacing

The spacing, S (m), of the screen material is the distance from the center of one strand of screen to the center of the adjacent one. The spacing of the screen material is assumed to be the same in both directions (e.g., vertical and horizontal). This input value must be greater than the non-zero screen material diameter. If the spacing is different in the two directions, use the average of the two values. Default value is 0.0025m.

#### 1.8.38.11 Field: Screen Wire Diameter

The diameter, D (m), of individual strands or wires of the screen material. The screen material diameter is assumed to be the same in both directions (e.g., vertical and horizontal). This input value must be greater than 0 and less than the screen wire spacing. If the diameter is different in the two directions, use the average of the two values. Default value is 0.005m.

An IDF example for this object, is shown below:

```
WindowMaterial:Screen:EquivalentLayer,

```

### 1.8.39 WindowMaterial:Glazing:EquivalentLayer

Glass material properties for equivalent layer window model. Uses transmittance/reflectance input method. For exterior windows, "front side" is the side of the glass closest to the outside air and "back side" is the side closest to the zone the window is defined in. For interzone windows, "front side" is the side closest to the zone adjacent to the zone the window is defined in and "back side" is the side closest to the zone the window is defined in.

#### 1.8.39.1 Field: Name

The name of the glass layer. It corresponds to a layer in an equivalent layer window construction.

#### 1.8.39.2 Field: Optical Data Type

Valid values for this field are SpectralAverage, or Spectral. If Optical Data Type = SpectralAverage, the values you enter for solar transmittance and reflectance are assumed to be averaged over the solar spectrum, and the values you enter for visible transmittance and reflectance are assumed to be averaged over the solar spectrum and weighted by the response of the human eye. The spectral data input is not supported now.

#### Field: Window Glass Spectral Data Set Name

This input field is not used currently.

#### 1.8.39.3 Field: Front Side Beam-Beam Solar Transmittance

This value is the front side beam-beam solar transmittance of the glazing at normal incidence averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0.

**1.8.39.4 Field: Back Side Beam-Beam Solar Transmittance**

This value is the back side beam-beam solar transmittance of the glazing at normal incidence averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0.

**1.8.39.5 Field: Front Side Beam-Beam Solar Reflectance**

This value is the front side beam-beam solar reflectance of the glazing at normal incidence averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0.

**1.8.39.6 Field: Back Side Beam-Beam Solar Reflectance**

This value is the back side beam-beam solar reflectance of the glazing at normal incidence averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0.

**1.8.39.7 Field: Front Side Beam-Beam Visible Transmittance**

This value is the front side beam-beam visible transmittance of the glazing at normal incidence averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0.

**1.8.39.8 Field: Back Side Beam-Beam Visible Transmittance**

This value is the back side beam-beam visible transmittance of the glazing at normal incidence averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0.

**1.8.39.9 Field: Front Side Beam-Beam Visible Reflectance**

This value is the front side beam-beam visible reflectance of the glazing at normal incidence averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0.

**1.8.39.10 Field: Back Side Beam-Beam Visible Reflectance**

This value is the back side beam-beam visible reflectance of the glazing at normal incidence averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0.

**1.8.39.11 Field: Front Side Beam-Diffuse Solar Transmittance**

This value is the front side beam-diffuse solar transmittance of the glazing at normal incidence averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. For clear glazing the beam-diffuse transmittance is zero. The minimum value is 0.0, and the maximum value is less than 1.0. Default value is 0.0.

**1.8.39.12 Field: Back Side Beam-Diffuse Solar Transmittance**

This value is the back side beam-diffuse solar transmittance of the glazing at normal incidence averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. For clear glazing the beam-diffuse solar transmittance is zero. The minimum value is 0.0, and the maximum value is less than 1.0. Default value is 0.0.

**1.8.39.13 Field: Front Side Beam-Diffuse Solar Reflectance**

This value is the front side beam-diffuse solar reflectance of the glazing at normal incidence averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0. Default value is 0.0.

**1.8.39.14 Field: Back Side Beam-Diffuse Solar Reflectance**

This value is the back side beam-diffuse solar reflectance of the glazing at normal incidence averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0. Default value is 0.0.

**1.8.39.15 Field: Front Side Beam-Diffuse Visible Transmittance**

This value is the front side beam-diffuse visible transmittance of the glazing at normal incidence averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. For clear glazing the beam-diffuse visible transmittance is zero. The minimum value is 0.0, and the maximum value is less than 1.0. Default value is 0.0. This input field is not used currently.

**1.8.39.16 Field: Back Side Beam-Diffuse Visible Transmittance**

This value is the back side beam-diffuse visible transmittance of the glazing at normal incidence averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. For clear glazing the beam-diffuse visible transmittance is zero. The minimum value is 0.0, and the maximum value is less than 1.0. Default value is 0.0. This input field is not used currently.

**1.8.39.17 Field: Front Side Beam-Diffuse Visible Reflectance**

This value is the front side beam-diffuse visible reflectance of the glazing at normal incidence averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0. Default value is 0.0. This input field is not used currently.

**1.8.39.18 Field: Back Side Beam-Diffuse Visible Reflectance**

This value is the back side beam-diffuse visible reflectance of the glazing at normal incidence averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. The minimum value is 0.0, and the maximum value is less than 1.0. Default value is 0.0. This input field is not used currently.

**1.8.39.19 Field: Diffuse-Diffuse Solar Transmittance**

This value is the diffuse-diffuse solar transmittance of the glazing averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. The diffuse-diffuse transmittance is assumed to be the same for both sides of the glazing. EnergyPlus automatically estimates the diffuse-diffuse solar transmittance from other inputs. If this input field is specified as "Autocalculate", then the calculated transmittance will be used. The minimum value is 0.0, and the maximum value is less than 1.0.

**1.8.39.20 Field: Front Side Diffuse-Diffuse Solar Reflectance**

This value is the front side diffuse-diffuse solar reflectance of the glazing averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. EnergyPlus automatically estimates the diffuse-diffuse reflectance from other inputs. If this input field is specified as "Autocalculate", then the calculated reflectance will be used. The minimum value is 0.0, and the maximum value is less than 1.0.

**1.8.39.21 Field: Back Side Diffuse-Diffuse Solar Reflectance**

This value is the back side diffuse-diffuse solar reflectance of the glazing averaged over the entire spectrum of solar radiation. Used only when Optical Data Type = SpectralAverage. EnergyPlus automatically estimates the diffuse-diffuse reflectance from other inputs. If this input field is specified as "Autocalculate", then the calculated reflectance will be used. The minimum value is 0.0, and the maximum value is less than 1.0.

**1.8.39.22 Field: Diffuse-Diffuse Visible Solar Transmittance**

This value is the diffuse-diffuse visible transmittance of the glazing averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. The diffuse-diffuse visible transmittance is assumed to be the same for both sides of the glazing. If this input field is specified as "Autocalculate", then the calculated transmittance will be used. The minimum value is 0.0, and the maximum value is less than 1.0. This input field is not used currently.

**1.8.39.23 Field: Front Side Diffuse-Diffuse Visible Reflectance**

This value is the front side diffuse-diffuse visible reflectance of the glazing averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. EnergyPlus automatically estimates the front side diffuse-diffuse visible reflectance from front side beam-beam visible reflectance at normal incidence specified above. If this input field is specified as "Autocalculate", then the calculated reflectance will be used. The minimum value is 0.0, and the maximum value is less than 1.0. This input field is not used currently.

**1.8.39.24 Field: Back Side Diffuse-Diffuse Visible Reflectance**

This value is the back side diffuse-diffuse visible reflectance of the glazing averaged over the visible spectrum range of solar radiation. Used only when Optical Data Type = SpectralAverage. EnergyPlus automatically estimates the back side diffuse-diffuse visible reflectance from back side beam-beam visible reflectance at normal incidence specified above. If this input field is specified as "Autocalculate", then the calculated reflectance will be used. The minimum value is 0.0, and the maximum value is less than 1.0. This input field is not used currently.

**1.8.39.25 Field: Infrared Transmittance (applies to front and back)**

This value is the long-wave hemispherical transmittance of the glazing. Assumed to be the same for both sides of the glazing. The minimum value is 0.0, the maximum value is less than 1.0. The default value is 0.0.

**1.8.39.26 Field: Front Side Infrared Emissivity**

This value is the front side long-wave hemispherical emissivity of the glazing. The minimum value is 0.0, the maximum value is less than 1.0. The default value is 0.84.

### 1.8.39.27 Field: Back Side Infrared Emissivity

This value is the back side long-wave hemispherical emissivity of the glazing. The minimum value is 0.0, the maximum value is less than 1.0. The default value is 0.84.

An IDF example for this object, is shown below:

### 1.8.40 WindowMaterial:Gap:EquivalentLayer

This object is used in windows equivalent layer construction object and specifies the properties of the gap between the layers in multi-layer equivalent layer window object. There is an EnergyPlus Reference Data Set for Material:WindowGas that contains several types of gas. This object uses the gas types: Air, Argon, Xenon, Crypton, and Custom. For Custom gas type users are required to entering the thermophysical properties.

#### 1.8.40.1 Field: Name

The name of the gap. It refers to a layer in a window construction equivalent layer.

#### 1.8.40.2 Field: Gas Type

The type of gas. The choices allowed are AIR, ARGON, XENON, KRYPTON, or CUSTOM.

#### 1.8.40.3 Field: Thickness

The thickness (m) of the gap layer.

#### 1.8.40.4 Field: Gap Vent Type

This input field contains the valid key choice for gap vent type. The valid vent types are: Sealed, VentedIndoor, and VentedOutdoor. Sealed means the gap is enclosed and gas tight, i.e., no venting to indoor or outdoor environment. The gap types "VentedIndoor" and "VentedOutdoor" are used with gas type "Air" only. VentedIndoor means the air in the gap is naturally vented to indoor environment, and VentedOutdoor means the air in the gap is naturally vented to the outdoor environment.

#### 1.8.40.5 Properties for Custom Gas Types

The following entries are used only if Gas Type = Custom. The A, B and C coefficients are those in the following expression that gives a property value as a function of temperature in degrees K:

$$Property = Coeff_A + Coeff_B \times Temperature_K + Coeff_C \times Temperature_K^2 \quad (16)$$

#### 1.8.40.6 Field: Conductivity Coefficient A

The A coefficient for gas conductivity (W/m-K). Used only if Gas Type = Custom.

#### 1.8.40.7 Field: Conductivity Coefficient B

The B coefficient for gas conductivity (W/m-K<sup>2</sup>). Used only if Gas Type = Custom.

#### 1.8.40.8 Field: Conductivity Coefficient C

The C coefficient for gas conductivity (W/m-K<sup>3</sup>). Used only if Gas Type = Custom.

#### 1.8.40.9 Field: Viscosity Coefficient A

The A coefficient for gas viscosity (kg/m-s). Used only if Gas Type = Custom.

#### 1.8.40.10 Field: Viscosity Coefficient B

The B coefficient for gas viscosity (kg/m-s-K). Used only if Gas Type = Custom.

#### 1.8.40.11 Field: Viscosity Coefficient C

The C coefficient for gas viscosity (kg/m-s-K<sup>2</sup>). Used only if Gas Type = Custom.

#### 1.8.40.12 Field: Specific Heat Coefficient A

The A coefficient for gas specific heat (J/kg-K). Used only if Gas Type = Custom.

#### 1.8.40.13 Field: Specific Heat Coefficient B

The B coefficient for gas specific heat (J/kg-K<sup>2</sup>). Used only if Gas Type = Custom.

#### 1.8.40.14 Field: Specific Heat Coefficient C

The C coefficient for gas specific heat (J/kg-K<sup>2</sup>). Used only if Gas Type = Custom.

#### 1.8.40.15 Field: Specific Heat Ratio

The specific heat ratio for gas. Used only if Gas Type = Custom.

#### 1.8.40.16 Field: Molecular Weight

The molecular weight for gas. The molecular weight is the mass of 1 mol of the substance. This has a numerical value which is the average molecular mass of the molecules in the substance multiplied by Avogadro's constant. (kg/kmol) (Shown in the IDD as g/mol for consistency)

#### 1.8.40.17 Field: Specific Heat Ratio

The specific heat ratio for gas. The specific heat ratio of a gas is the ratio of the specific heat at constant pressure, to the specific heat at constant volume. Used only if Gas Type = Custom.

An IDF example for this object, is shown below:

```
WindowMaterial:Gap:EquivalentLayer,
  Custom CO2 Sealed 12mm,    !- Name
  CUSTOM,                   !- Gas Type
  0.0120,                    !- Thickness {m}
  Sealed,                   !- Gap Vent Type
-5.8181E-3,                 !- Conductivity Coefficient A {W/m-K}
  7.4714E-5,                 !- Conductivity Coefficient B {W/m-K2}
  0.0,                       !- Conductivity Coefficient C {W/m-K3}
  8.5571E-7,                 !- Viscosity Coefficient A {kg/m-s}
  4.7143E-8,                 !- Viscosity Coefficient B {kg/m-s-K}
  0.0,                       !- Viscosity Coefficient C {kg/m-s-K2}
  5.76903E2,                 !- Specific Heat Coefficient A {J/kg-K}
  9.18088E-2,                !- Specific Heat Coefficient B {J/kg-K2}
  0.0,                       !- Specific Heat Coefficient C {J/kg-K3}
  44.01;                    !- Molecular Weight {g/mol}
```

#### 1.8.41 Material:RoofVegetation

This definition must be used in order to simulate the green roof (ecorooft) model. The material becomes the outside layer in a green roof construction (see example below). In the initial release of the green roof model, only one material may be used as a green roof layer though, of course, several constructions using that material may be used. In addition, the model has only been tested with the ConductionTransferFunction solution algorithm – a warning will be issued for other solution algorithm choices. This model was developed for low-sloped exterior surfaces (roofs). It is not recommended for high-sloped exterior surfaces

(e.g., walls).

#### **1.8.41.1 Field: Name**

This field is a unique reference name that the user assigns to a particular ecoroof material. This name can then be referred to by other input data.

#### **1.8.41.2 Field: Height of Plants**

This field defines the height of plants in units of meters. This field is limited to values in the range  $0.005 < \text{Height} < 1.00$  m. Default is .2 m.

#### **1.8.41.3 Field: Leaf Area Index**

This is the projected leaf area per unit area of soil surface. This field is dimensionless and is limited to values in the range of  $0.001 < \text{LAI} < 5.0$ . Default is 1.0. At the present time the fraction vegetation cover is calculated directly from LAI (Leaf Area Index) using an empirical relation. The user may find it necessary to increase the specified value of LAI in order to represent high fractional coverage of the surface by vegetation.

#### **1.8.41.4 Field: Leaf Reflectivity**

This field represents the fraction of incident solar radiation that is reflected by the individual leaf surfaces (albedo). Solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. Values for this field must be between 0.05 and 0.5. Default is .22. Typical values are .18 to .25.

#### **1.8.41.5 Field: Leaf Emissivity**

This field is the ratio of thermal radiation emitted from leaf surfaces to that emitted by an ideal black body at the same temperature. This parameter is used when calculating the long wavelength radiant exchange at the leaf surfaces. Values for this field must be between 0.8 and 1.0 (with 1.0 representing "black body" conditions). Default is .95.

#### **1.8.41.6 Field: Minimum Stomatal Resistance**

This field represents the resistance of the plants to moisture transport. It has units of s/m. Plants with low values of stomatal resistance will result in higher evapotranspiration rates than plants with high resistance. Values for this field must be in the range of 50.0 to 300.0. Default is 180.

#### **1.8.41.7 Field: Soil Layer Name**

This field is a unique reference name that the user assigns to the soil layer for a particular ecoroof. This name can then be referred to by other input data. Default is **Green Roof Soil**.

#### **1.8.41.8 Field: Roughness**

This alpha field defines the relative roughness of a particular material layer. This parameter only influences the convection coefficients, more specifically the exterior convection coefficient. A keyword is expected in this field with the options being "VeryRough", "Rough", "MediumRough", "MediumSmooth", "Smooth", and "VerySmooth" in order of roughest to smoothest options. Default is MediumRough.

#### **1.8.41.9 Field: Thickness**

This field characterizes the thickness of the material layer in meters. This should be the dimension of the layer in the direction perpendicular to the main path of heat conduction. This value must be a positive number. Depths of .10m (4 inches) and .15m (6 inches) are common. Default if this field is left blank is .1. Maximum is .7m. Must be greater than .05 m.

#### **1.8.41.10 Field: Conductivity of Dry Soil**

This field is used to enter the thermal conductivity of the material layer. Units for this parameter are  $W/(m-K)$ . Thermal conductivity must be greater than zero. Typical soils have values from .3 to .5. Minimum is .2 (specified in IDD). Default is .35 and maximum (in IDD) is 1.5.

#### **1.8.41.11 Field: Density of Dry Soil**

This field is used to enter the density of the material layer in units of  $kg/m^3$ . Density must be a positive quantity. Typical soils range from 400 to 1000 (dry to wet). Minimum is 300, maximum is 2000 and default if field is left blank is 1100.

#### **1.8.41.12 Field: Specific Heat of Dry Soil**

This field represents the specific heat of the material layer in units of  $J/(kg-K)$ . Note that these units are most likely different than those reported in textbooks and references which tend to use  $kJ/(kg-K)$  or  $J/(g-K)$ . They were chosen for internal consistency within EnergyPlus. Only positive values of specific heat are allowed.

#### **1.8.41.13 Field: Thermal Absorptance**

The thermal absorptance field in the Material input syntax represents the fraction of incident long wavelength radiation that is absorbed by the material. This

parameter is used when calculating the long wavelength radiant exchange between various surfaces and affects the surface heat balances (both inside and outside as appropriate). For long wavelength radiant exchange, thermal emissivity and thermal emittance are equal to thermal absorptance. Values for this field must be between 0.0 and 1.0 (with 1.0 representing "black body" conditions). Typical values are from .9 to .98. The default value for this field is 0.9.

#### 1.8.41.14 Field: Solar Absorptance

The solar absorptance field in the Material input syntax represents the fraction of incident solar radiation that is absorbed by the material. Solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the amount of incident solar radiation absorbed by various surfaces and affects the surface heat balances (both inside and outside as appropriate). If solar reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials). Values for this field must be between 0.0 and 1.0. Typical values are from .6 to .85. The default value for this field is 0.7.

#### 1.8.41.15 Field: Visible Absorptance

The visible absorptance field in the Material input syntax represents the fraction of incident visible wavelength radiation that is absorbed by the material. Visible wavelength radiation is slightly different than solar radiation in that the visible band of wavelengths is much more narrow while solar radiation includes the visible spectrum as well as infrared and ultraviolet wavelengths. This parameter is used when calculating the amount of incident visible radiation absorbed by various surfaces and affects the surface heat balances (both inside and outside as appropriate) as well as the daylighting calculations. If visible reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials). Values for this field must be between 0.5 and 1.0. The default value for this field is 0.75.

#### 1.8.41.16 Field: Saturation Volumetric Moisture Content of the Soil Layer

The field allows for user input of the saturation moisture content of the soil layer. Maximum moisture content is typically less than .5. Range is [.1,.5] with the default being .3.

#### 1.8.41.17 Field: Residual Volumetric Moisture Content of the Soil Layer

The field allows for user input of the residual moisture content of the soil layer. Default is .01, range is [.01,.1].

#### 1.8.41.18 Field: Initial Volumetric Moisture Content of the Soil Layer

The field allows for user input of the initial moisture content of the soil layer. Range is (.05, .5] with the default being .1.

#### 1.8.41.19 Field: Moisture Diffusion Calculation Method

The field allows for two models to be selected: **Simple** or **Advanced**.

**Simple** is the original Ecoroof model - based on a constant diffusion of moisture through the soil. This model starts with the soil in two layers. Every time the soil properties update is called, it will look at the two soils moisture layers and asses which layer has more moisture in it. It then takes moisture from the higher moisture layer and redistributes it to the lower moisture layer at a constant rate.

**Advanced** is the later Ecoroof model. If you use it, you will need to increase your number of timesteps in hour for the simulation with a recommended value of 20. This moisture transport model is based on a project which looked at the way moisture transports through soil. It uses a finite difference method to divide the soil into layers (nodes). It redistributes the soil moisture according to the model described in:

Marcel G Schaap and Martinus Th. van Genuchten, 2006, 'A modified Maulem-van Genuchten Formulation for Improved Description of the Hydraulic Conductivity Near Saturation', Vadose Zone Journal 5 (1), p 27-34.

## 1.8.42 Ecoroof / RoofVegetation outputs

The following outputs are available for the Roof Vegetation surface.

- Zone,Average,Green Roof Soil Temperature [C]
- Zone,Average,Green Roof Vegetation Temperature [C]
- Zone,Average,Green Roof Soil Root Moisture Ratio []
- Zone,Average,Green Roof Soil Near Surface Moisture Ratio []
- Zone,Average,Green Roof Soil Sensible Heat Transfer Rate per Area [W/m2]
- Zone,Average,Green Roof Vegetation Sensible Heat Transfer Rate per Area [W/m2]
- Zone,Average,Green Roof Vegetation Moisture Transfer Rate [m/s]
- Zone,Average,Green Roof Soil Moisture Transfer Rate [m/s]
- Zone,Average,Green Roof Vegetation Latent Heat Transfer Rate per Area [W/m2]
- Zone,Average,Green Roof Soil Latent Heat Transfer Rate per Area [W/m2]
- Zone,Sum,Green Roof Cumulative Precipitation Depth [m]
- Zone,Sum,Green Roof Cumulative Irrigation Depth [m]
- Zone,Sum,Green Roof Cumulative Runoff Depth [m]
- Zone,Sum,Green Roof Cumulative Evapotranspiration Depth [m]
- Zone,Sum,Green Roof Current Precipitation Depth [m]
- Zone,Sum,Green Roof Current Irrigation Depth [m]
- Zone,Sum,Green Roof Current Runoff Depth [m]
- Zone,Sum,Green Roof Current Evapotranspiration Depth [m]

### 1.8.42.1 Green Roof Soil Temperature [C]

Temperature of the Soil layer temperature in C.

### 1.8.42.2 Green Roof Vegetation Temperature [C]

Temperature of the Vegetation layer temperature in C.

#### 1.8.42.3 Green Roof Soil Root Moisture Ratio []

Mean value of root moisture ( $m^3/m^3$ )

#### 1.8.42.4 Green Roof Soil Near Surface Moisture Ratio []

The moisture content in the soil near the surface ( $m^3/m^3$ )

#### 1.8.42.5 Green Roof Soil Sensible Heat Transfer Rate per Area [W/m2]

Sensible heat flux to ground ( $W/m^2$ )

#### 1.8.42.6 Green Roof Vegetation Sensible Heat Transfer Rate per Area [W/m2]

Sensible heat transfer to foliage ( $W/m^2$ )

#### 1.8.42.7 Green Roof Vegetation Moisture Transfer Rate [m/s]

Water evapotranspiration rate associated with latent heat from vegetation (m/s)

#### 1.8.42.8 Green Roof Soil Moisture Transfer Rate [m/s]

Water evapotranspiration rate associated with latent heat from ground surface (m/s)

#### 1.8.42.9 Green Roof Vegetation Latent Heat Transfer Rate per Area [W/m2]

Latent heat flux from vegetation ( $W/m^2$ )

#### 1.8.42.10 Green Roof Soil Latent Heat Transfer Rate per Area [W/m2]

Latent heat flux from ground surface ( $W/m^2$ )

#### 1.8.42.11 Green Roof Cumulative Precipitation Depth [m]

#### 1.8.42.12 Green Roof Current Precipitation Depth [m]

Cumulative or current precipitation (m)

#### 1.8.42.13 Green Roof Cumulative Irrigation Depth [m]

#### 1.8.42.14 Green Roof Current Irrigation Depth [m]

Cumulative or current irrigation (m)

#### 1.8.42.15 Green Roof Cumulative Runoff Depth [m]

#### 1.8.42.16 Green Roof Current Runoff Depth [m]

Cumulative or current runoff (m). Multiply by roof area to get volume.

#### 1.8.42.17 Green Roof Cumulative Evapotranspiration Depth [m]

#### 1.8.42.18 Green Roof Current Evapotranspiration Depth [m]

Cumulative or current evapotranspiration from soil and plants (m).

### 1.8.43 MaterialProperty:GlazingSpectralData

With the MaterialProperty:GlazingSpectralData object, you can specify the wavelength-by-wavelength transmittance and reflectance properties of a glass material. To determine the overall optical properties of a glazing system (solar and visible transmittance and solar absorptance vs. angle of incidence) EnergyPlus first calculates transmittance and absorptance vs. angle of incidence for each wavelength. This is then weighted by a standard solar spectrum to get the solar transmittance and absorptance vs. angle of incidence (for use in the solar heat gain calculations), and further weighted by the response of the human eye to get the visible transmittance vs. angle of incidence (for use in the daylighting calculation).

MaterialProperty:GlazingSpectralData should be used for multi-pane windows when one or more of the glass layers is *spectrally selective*, i.e., the transmittance depends strongly on wavelength. An example is glass with a coating that gives high transmittance in the daylight part of the solar spectrum (roughly 0.4 to 0.7

microns) and low transmittance at longer wavelengths, thus providing better solar heat gain control than uncoated glass. If spectral data is not used in case, the overall optical properties of the glazing system that EnergyPlus calculates will not be correct.

You can input up to 450 sets of values for wavelengths covering the solar spectrum. Each set consists of {wavelength (microns), transmittance, front reflectance, back reflectance}

Spectral data of this kind are routinely measured by glass manufacturers. Data sets for over 800 commercially available products are contained in an Optical Data Library maintained by the Windows Group at Lawrence Berkeley National Laboratory. This library can be downloaded from <http://windows.lbl.gov/>. You will have to edit entries from this library to put them in the format required by the EnergyPlus WindowGlassSpectralData object.

An alternative to using the MaterialProperty:GlazingSpectralData object is to run the WINDOW window analysis program. This program has built-in access to the Optical Data Library and let's you easily create customized, multi-layer glazing systems that can be exported for use in EnergyPlus. For more details, see "StormWindow".

#### 1.8.43.1 Field: Name

The name of the spectral data set. It is referenced by WindowMaterial:Glazing when Optical Data Type = Spectral.

#### 1.8.43.2 Fields 1-4 (repeated up to 450 times)

Sets of values for wavelengths covering the solar spectrum (from about 0.25 to 2.5 microns [ $10^6$  m]). Each set consists of

**{wavelength (microns), transmittance, front reflectance, back reflectance}**

The wavelength values must be in ascending order. The transmittance and reflectance values are at normal incidence. "Front reflectance" is the reflectance for radiation striking the glass from the outside, i.e., from the side opposite the zone in which the window is defined. "Back reflectance" is the reflectance for radiation striking the glass from the inside, i.e., from the zone in which the window is defined. Therefore, for exterior windows, "front" is the side closest to the outdoors and "back" is the side closest to the zone in which the window is defined. For interior windows, "front" is the side closest to the adjacent zone and "back" is the side closest to the zone in which the window is defined.

An IDF example:

### 1.8.44 Construction

For walls, roofs, floors, windows, and doors, constructions are "built" from the included materials. Each layer of the construction is a material name listed in order from "outside" to "inside". Up to ten layers (eight for windows) may be specified (one of the few limitations in EnergyPlus!). "Outside" is the layer furthest away from the Zone air (not necessarily the outside environment). "Inside" is the layer next to the Zone air. In the example floor below, for example, the outside layer is the acoustic tile below the floor, the next layer is the air space above the tile, and the inside layer is the concrete floor deck.

Figure 24. Example Floor Construction illustration.

Window constructions are similarly built up from items in the Window Materials set using similar layers.. See Figure 25. Illustration for material ordering in windows, which shows the case where an interior shading layer such as a blind is present. The gap between the inside glass layer (layer #3) and the interior shading layer is not entered. Similarly, for an exterior shading layer, the gap between the outside glass layer and the shading layer is not entered.

Figure 25. Illustration for material ordering in windows.

However, for a between-glass shading device the gaps on either side of the shading layer must be entered and they must have the same gas type. In addition, the gap widths with and without the between-glass shading layer must be consistent (see Figure 26).

A maximum of four glass layers and one shading layer is allowed. A gas layer must always separate adjacent glass layers in a multi-pane glazing without a between-glass shading layer.

Figure 26. Window construction with and without a between-glass shading layer. Shown are gap widths  $g$ ,  $g_1$  and  $g_2$ , and shading layer width,  $w$ . An error will result if  $g_1 + g_2 + w$  is not equal to  $g$ , where  $w$  is zero for a blind and greater than zero for a shade.

Outside and inside air film resistances are never given as part of a construction definitions since they are calculated during the EnergyPlus simulation. Note also that constructions are assumed to be one-dimensional in a direction perpendicular to the surface.

#### 1.8.44.1 Field: Name

This field is a user specified name that will be used as a reference by other input syntax. For example, a heat transfer surface (ref: Building Surfaces) requires a construction name to define what the make-up of the wall is. This name must be identical to one of the Construction definitions in the input data file.

#### 1.8.44.2 Field: Outside Layer

Each construction must have at least one layer. This field defines the material name associated with the layer on the outside of the construction—outside referring to the side that is not exposed to the zone but rather the opposite side environment, whether this is the outdoor environment or another zone. Material layers are defined based on their thermal properties elsewhere in the input file (ref: Material and Material Properties and Zone,Average,HAMT Surface Average Water Content Ratio [kg/kg])

Zone,Average,HAMT Surface Inside Face Temperature [C]

Zone,Average,HAMT Surface Inside Face Relative Humidity [%]

Zone,Average,HAMT Surface Inside Face Vapor Pressure [Pa]

Zone,Average,HAMT Surface Outside Face Temperature [C]

Zone,Average,HAMT Surface Outside Face Relative Humidity [%]

Zone,Average,HAMT Surface Inside Face Relative Humidity [%]

#### 1.8.44.3 HAMT Surface Average Water Content Ratio [kg/kg]

This output is the summed water content [kg/kg] of all cells in a surface expressed as a fraction of the mass of the water to the material mass.

#### 1.8.44.4 HAMT Surface Inside Face Temperature [C]

This output is the temperature [C] on the internal “surface” of the surface.

#### 1.8.44.5 HAMT Surface Inside Face Relative Humidity [%]

#### 1.8.44.6 HAMT Surface Inside Face Relative Humidity [%]

This output is the relative humidity on the internal “surface” of the surface expressed as a percentage.

#### 1.8.44.7 HAMT Surface Inside Face Vapor Pressure [Pa]

This output is the vapor pressure [Pa] on the internal “surface” of the surface.

#### 1.8.44.8 HAMT Surface Outside Face Temperature [C]

This output is the temperature on the external “surface” of the surface.

#### 1.8.44.9 HAMT Surface Outside Face Relative Humidity [%]

This output is the relative humidity on the external “surface” of the surface.

Zone,Average,HAMT Surface Temperature Cell N [C]

Zone,Average,HAMT Surface Water Content Cell N [kg/kg]

Zone,Average,HAMT Surface Relative Humidity Cell N [%]

Detailed profile data for the variables Temperature [C], Relative Humidity [%] and Water Content [kg/kg] within each surface can also be reported. To calculate the heat and moisture transfer through surfaces HAMT splits up surfaces into discrete cells. Each cell is composed of a single material and has a position within the surface. HAMT automatically assigns cells to construction objects so that there are more cells closer to boundaries between materials and also at the “surfaces” of the surface. It is not possible for users to define their own cells.

#### 1.8.44.10 HAMT Surface Relative Humidity Cell <N> [%]

This is the relative humidity of the cell in the surface.

#### 1.8.44.11 HAMT Surface Temperature Cell <N> [C]

This is the temperature of the cell in the surface.

#### 1.8.44.12 HAMT Surface Water Content Cell <N> [kg/kg]

This is the relative water content of the cell in the surface.

Each surface is made from a particular construction. The construction-surface relationship is output by HAMT to the eplusout.eio file with the following format.

! <HAMT cells>, Surface Name, Construction Name, Cell Numbers

! <HAMT origins>, Surface Name, Construction Name, Cell origins (m)

The output also contains the HAMT cell origins and cell number for each construction – surface combination. The coordinate system origin is defined as the exterior surface of the construction. Users can select any one of the Temperature, Relative Humidity or Water Content variables for any cell to be reported, using the following naming scheme for the output variable.

HAMT Profile Construction <Variable> Cell <Cell#>

It is better to specify the “key” or Surface Name in this output.

So for example to output the temperature of the 10<sup>th</sup> cell in a surface, eg “East Wall” would require the following output variable.

```
Output:Variable,  
      East Wall,           !- Key Value  
      HAMT Profile Construction Temperature Cell 10, !- Variable Name  
      Hourly;              !- Reporting Frequency
```

By selecting a whole range of these reports and using the information in the eplusout.eio file it is possible to build up a temperature profile of the surface.

Materials for Glass Windows and Doors). As noted above, the outside layer should NOT be a film coefficient since EnergyPlus will calculate outside convection and radiation heat transfer more precisely.

#### 1.8.44.13 Field(s) 2-10: Layers

The next fields are optional and the number of them showing up in a particular Construction definition depends solely on the number of material layers present in that construction. The data expected is identical to the outside layer field (see previous field description). The order of the remaining layers is important and

should be listed in order of occurrence from the one just inside the outside layer until the inside layer is reached. As noted above, the inside layer should NOT be a film coefficient since EnergyPlus will calculate inside convection and radiation heat transfer more precisely.

IDF Example (floor construction):

```
Construction, FLOOR38, ! Material layer names follow:
E5 - ACOUSTIC TILE,
E4 - CEILING AIRSPACE,
C12 - 2 IN HW CONCRETE;
```

IDF Example (window construction, no shade):

```
Construction, DOUBLE PANE WINDOW, !- Material layer names follow:
GLASS - CLEAR SHEET 1 / 8 IN,
WinAirB1 - AIRSPACE RESISTANCE,
GLASS - CLEAR SHEET 1 / 8 IN;
```

IDF Example (window construction, with interior shade):

```
Construction, DOUBLE PANE WITH ROLL SHADE, !- Material layer names follow:
GLASS - CLEAR SHEET 1 / 8 IN,
WinAirB1 - AIRSPACE RESISTANCE,
GLASS - CLEAR SHEET 1 / 8 IN,
ROLL SHADE - LIGHT
```

### 1.8.45 Site:GroundTemperature:FCfactorMethod

Site:GroundTemperature:FCfactorMethod is used only by the underground walls or slabs-on-grade or underground floors defined with C-factor (Construction:CfactorUndergroundWall) and F-factor (Construction:FfactorGroundFloor) method for code compliance calculations where detailed construction layers are unknown. Only one such ground temperature object can be included. The monthly ground temperatures for this object are close to the monthly outside air temperatures delayed by three months. If user does not input this object in the IDF file, it will be defaulted to the 0.5m set of monthly ground temperatures from the weather file if they are available.

#### 1.8.45.1 Field: Month Temperature(s) – 12 fields in all

Each numeric field is the monthly ground temperature (degrees Celsius) used for the indicated month (January=<sup>1</sup>st field, February=<sup>2</sup>nd field, etc.)

And, the IDF example:

```
Site:GroundTemperature:FCfactorMethod, 9.5,3.5,-0.7,-1.7,-0.6,3.6,9.3,14,18.2,22.7,21.2,16.8;
```

### 1.8.46 Constructions - Modeling Underground Walls and Ground Floors Defined with C and F Factors for Building Energy Code Compliance

Building energy code and standards like ASHRAE 90.1, 90.2 and California Title 24 require the underground wall constructions and slabs-on-grade or underground floors not to exceed certain maximum values of C-factor and F-factor, which do not specify detailed layer-by-layer materials for the constructions.

A simplified approach is introduced to create equivalent constructions and model the ground heat transfer through underground walls and ground floors for the building energy code compliance calculations. The approach is to create constructions based on the user defined C or F factor with two layers: one concrete layer (0.15 m thick) with thermal mass, and one fictitious insulation layer with no thermal mass. Three new objects were created for such purpose:

**Construction:CfactorUndergroundWall**, **Construction:FfactorGroundFloor**, and **Site:GroundTemperature:FCfactorMethod**. Details of the approach are described in the Engineering Reference document. The wall and floor construction objects are described in this section; the ground temperature object is described with the other ground temperature objects.

When a underground wall or ground floor surface (BuildingSurface:Detailed, Floor:Detailed, and Wall:Detailed) references one of the two construction objects, its field 'Outside Boundary Condition' needs to be set to GroundFCfactorMethod. For simple (rectangular) wall and floor objects, the outside boundary condition is inferred from the construction type.

The Site:GroundTemperature:FCfactorMethod is described in the section for ground temperatures, the following section describes the two new construction objects.

#### 1.8.47 Construction:CfactorUndergroundWall

This input object differs from the usual wall construction object in that it describes an entire construction rather than individual layers. This object is used when only the wall height (depth to the ground) and the C-factor are available. This object accesses a model that creates an equivalent layer-by-layer construction for the underground wall to approximate the heat transfer through the wall considering the thermal mass of the earth soil.

This object is referenced by underground wall surfaces with their fields 'Outside Boundary Condition' set to GroundFCfactorMethod.

##### 1.8.47.1 Field: Name

The name of the underground wall construction.

### 1.8.47.2 Field: C-Factor

C-Factor is the time rate of steady-state heat flow through unit area of the construction, induced by a unit temperature difference between the body surfaces. The C-Factor unit is  $W/m^2 \cdot K$ . The C-factor does not include soil or air films. ASHRAE Standard 90.1 and California Title 24 specify maximum C-factors for underground walls depending on space types and climate zones.

### 1.8.47.3 Field: Height

This field describes the height of the underground wall, i.e. the depth to the ground surface. The unit is meters.

IDF Example:

```
Construction:CfactorUndergroundWall,
  CfactorUGWall,
  0.436,          ! C-factor (W/m2K), does not include soil or air films
  4.57;          ! Height (m)
```

```
BuildingSurface:Detailed,
  Zn001:Wall001,    !- Name
  Wall,             !- Surface Type
  CfactorUGWall,    !- Construction Name
  ZONE ONE,         !- Zone Name
  GroundFCfactorMethod, !- Outside Boundary Condition
  ,                 !- Outside Boundary Condition Object
  NoSun,            !- Sun Exposure
  NoWind,           !- Wind Exposure
  0.0,              !- View Factor to Ground
  4,                !- Number of Vertices
  0.0,0.0,4.572,    !- X,Y,Z ==> Vertex 1
  0.0,0.0,0.0,     !- X,Y,Z ==> Vertex 2
  15.24,0.0,0.0,   !- X,Y,Z ==> Vertex 3
  15.24,0.0,4.572; !- X,Y,Z ==> Vertex 4
```

### 1.8.48 Construction:FfactorGroundFloor

This input object differs from the usual ground floor construction object in that it describes an entire construction rather than individual layers. This object is used when only the floor area, exposed perimeter, and the F-factor are available. This object accesses a model that creates an equivalent layer-by-layer construction for the slab-on-grade or underground floor to approximate the heat transfer through the floor considering the thermal mass of the earth soil.

This object is referenced by slab-on-grade or underground floor surfaces with their fields 'Outside Boundary Condition' set to GroundFCfactorMethod.

#### 1.8.48.1 Field: Name

The name of the ground floor construction.

#### 1.8.48.2 Field: F-Factor

F-Factor represents the heat transfer through the floor, induced by a unit temperature difference between the outside and inside air temperature, on the per linear length of the exposed perimeter of the floor. The unit for this input is  $W/m \cdot K$ . ASHRAE Standard 90.1 and California Title 24 specify maximum F-factors for slab-on-grade or underground floors depending on space types and climate zones.

#### 1.8.48.3 Field: Area

This field describes the area (in square meters) of the slab-on-grade or underground floor.

#### 1.8.48.4 Field: PerimeterExposed

This field describes the exposed (direct contact with ambient air) perimeter (in meters) of the slab-on-grade or underground floor.

IDF Example:

```
Construction:FfactorGroundFloor,
  slabconst,
  0.12,          !F-factor in W/m-K
  232.26,       !Area in m2
  61.0;         !Exposed perimeter in m
```

```
BuildingSurface:Detailed,
  Zn001:Flr001,    !- Name
  Floor,           !- Surface Type
  slabconst,       !- Construction Name, FLOOR
  ZONE ONE,        !- Zone Name
```

```

GroundFCfactorMethod,    !- Outside Boundary Condition, Surface
,                        !- Outside Boundary Condition Object, Zn001:Flr001
NoSun,                  !- Sun Exposure
NoWind,                 !- Wind Exposure
0,                      !- View Factor to Ground
4,                      !- Number of Vertices
15.24,0.0,0.0,          !- X,Y,Z ==> Vertex 1
0.0,0.0,0.0,           !- X,Y,Z ==> Vertex 2
0.0,15.240,0.0,        !- X,Y,Z ==> Vertex 3
15.24,15.24,0.0;       !- X,Y,Z ==> Vertex 4

```

### 1.8.49 Construction:InternalSource

In some cases such as radiant systems, a construction will actually have resistance wires or hydronic tubing embedded within the construction. Heat is then either added or removed from this building element to provide heating or cooling to the zone in question. In the case of building-integrated photovoltaics, the energy removed in the form of electricity will form a sink. It is possible to enter such constructions into EnergyPlus with the syntax described below. The definition is similar to the Construction definition with a few additions related to radiant or other systems that will lead to source/sink terms. The internal source capability is available with both the **ConductionTransferFunction** and **ConductionFiniteDifference** solution algorithms. The only difference is that the two dimensional pipe arrangements are not available to ConductionFiniteDifference. Those fields are ignored in that implementation.

#### 1.8.49.1 Field: Name

This field is a user specified name that will be used as a reference by other input syntax. For example, a heat transfer surface (ref: Building Surfaces) requires a construction name to define what the make-up of the wall is.

#### 1.8.49.2 Field: Source Present After Layer Number

This field is an integer that relates the location of the heat source or sink. The integer refers to the list of material layers that follow later in the syntax and determines the layer after which the source is present. If a source is embedded within a single homogenous layer (such as concrete), that layer should be split into two layers and the source added between them. For example, a value of “2” in this field tells EnergyPlus that the source is located between the second and third material layers listed later in the construction description (see layer fields below).

#### 1.8.49.3 Field: Temperature Calculation Requested After Layer Number

The nature of this field is similar to the source interface parameter (see previous field) in that it is an integer, refers to the list of material layers that follow, and defines a location after the layer number identified by the user-defined number. In this case, the user is specifying the location for a separate temperature calculation rather than the location of the heat source/sink. This feature is intended to allow users to calculate a temperature within the construction. This might be important in a radiant cooling system where condensation could be a problem. This temperature calculation can assist users in making that determination in absence of a full heat and mass balance calculation.

#### 1.8.49.4 Field: Dimensions for the CTF Calculation

This field is also an integer and refers to the detail level of the calculation. A value of “1” states that the user is only interested in a one-dimensional calculation. This is appropriate for electric resistance heating and for hydronic heating (when boiler/hot water heater performance is not affected by return and supply water temperatures). A value of “2” will trigger a two-dimensional solution for this surface only. This may be necessary for hydronic radiant cooling situations since chiller performance is affected by the water temperatures provided.

A few things should be noted about requesting two-dimensional solutions. First, the calculation of the conduction transfer functions (CTF) is fairly intensive and will require a significant amount of computing time. Second, the solution regime is two-dimensional internally but it has a one-dimensional boundary condition imposed at the inside and outside surface (i.e., surface temperatures are still isothermal as if the surface was one-dimensional).

#### 1.8.49.5 Field: Tube Spacing

This field defines how far apart in meters the hydronic tubing or electrical resistance wires are spaced in the direction perpendicular to the main direction of heat transfer. Note that this parameter is only used for two-dimensional solutions (see previous field).

#### 1.8.49.6 Field: Outside Layer

Each construction must have at least one layer. This field defines the material name associated with the layer on the outside of this construction—outside referring to the side that is not exposed to the zone but rather the opposite side environment, whether this is the outdoor environment or another zone. Material layers are defined based on their thermal properties elsewhere in the input file (ref: Material and Material Properties and Zone,Average,HAMT Surface Average Water Content Ratio [kg/kg])

Zone,Average,HAMT Surface Inside Face Temperature [C]

Zone,Average,HAMT Surface Inside Face Relative Humidity [%]

Zone,Average,HAMT Surface Inside Face Vapor Pressure [Pa]

Zone,Average,HAMT Surface Outside Face Temperature [C]

Zone,Average,HAMT Surface Outside Face Relative Humidity [%]

Zone,Average,HAMT Surface Inside Face Relative Humidity [%]

#### **1.8.49.7 HAMT Surface Average Water Content Ratio [kg/kg]**

This output is the summed water content [kg/kg] of all cells in a surface expressed as a fraction of the mass of the water to the material mass.

#### **1.8.49.8 HAMT Surface Inside Face Temperature [C]**

This output is the temperature [C] on the internal “surface” of the surface.

#### **1.8.49.9 HAMT Surface Inside Face Relative Humidity [%]**

#### **1.8.49.10 HAMT Surface Inside Face Relative Humidity [%]**

This output is the relative humidity on the internal “surface” of the surface expressed as a percentage.

#### **1.8.49.11 HAMT Surface Inside Face Vapor Pressure [Pa]**

This output is the vapor pressure [Pa] on the internal “surface” of the surface.

#### **1.8.49.12 HAMT Surface Outside Face Temperature [C]**

This output is the temperature on the external “surface” of the surface.

#### **1.8.49.13 HAMT Surface Outside Face Relative Humidity [%]**

This output is the relative humidity on the external “surface” of the surface.

Zone,Average,HAMT Surface Temperature Cell N [C]

Zone,Average,HAMT Surface Water Content Cell N [kg/kg]

Zone,Average,HAMT Surface Relative Humidity Cell N [%]

Detailed profile data for the variables Temperature [C], Relative Humidity [%] and Water Content [kg/kg] within each surface can also be reported. To calculate the heat and moisture transfer through surfaces HAMT splits up surfaces into discrete cells. Each cell is composed of a single material and has a position within the surface. HAMT automatically assigns cells to construction objects so that there are more cells closer to boundaries between materials and also at the “surfaces” of the surface. It is not possible for users to define their own cells.

#### **1.8.49.14 HAMT Surface Relative Humidity Cell <N> [%]**

This is the relative humidity of the cell in the surface.

#### **1.8.49.15 HAMT Surface Temperature Cell <N> [C]**

This is the temperature of the cell in the surface.

#### **1.8.49.16 HAMT Surface Water Content Cell <N> [kg/kg]**

This is the relative water content of the cell in the surface.

Each surface is made from a particular construction. The construction-surface relationship is output by HAMT to the eplusout.eio file with the following format.

! <HAMT cells>, Surface Name, Construction Name, Cell Numbers

! <HAMT origins>, Surface Name, Construction Name, Cell origins (m)

The output also contains the HAMT cell origins and cell number for each construction – surface combination. The coordinate system origin is defined as the exterior surface of the construction. Users can select any one of the Temperature, Relative Humidity or Water Content variables for any cell to be reported, using the following naming scheme for the output variable.

HAMT Profile Construction <Variable> Cell <Cell#>

It is better to specify the “key” or Surface Name in this output.

So for example to output the temperature of the 10<sup>th</sup> cell in a surface, eg “East Wall” would require the following output variable.

```
Output:Variable,
      East Wall,           !- Key Value
      HAMT Profile Construction Temperature Cell 10, !- Variable Name
      Hourly;             !- Reporting Frequency
```

By selecting a whole range of these reports and using the information in the eplusout.eio file it is possible to build up a temperature profile of the surface.

Materials for Glass Windows and Doors). As noted above, the outside layer should NOT be a film coefficient since EnergyPlus will calculate convection and radiation heat transfer more precisely.

#### 1.8.49.17 Field(s) 2-10: Layers

The next fields are optional and the number of them showing up in a particular Construction definition depends solely on the number of material layers present in that particular construction. The data expected is identical to the outside layer field (see previous field description). The order of the remaining layers is important and should be listed in order of occurrence from the one just inside the outside layer until the inside layer is reached. As noted above, the inside layer should NOT be a film coefficient since EnergyPlus will calculate convection and radiation heat transfer more precisely.

### 1.8.50 Composite Wall Constructions

Standard constructions in EnergyPlus are built with the materials and layers described earlier. However, some configurations will not be adequately represented by using this approach. The Reference Data Set CompositeWallConstructions.idf contains constructions and associated materials for a set of **composite** walls. These are walls—such as stud walls—that have complicated heat-flow paths so that the conduction is two- or three-dimensional. Thermal bridges are one of the common terms for these complicated heat-flow paths; this dataset will help you represent these in EnergyPlus.

The materials here are **not** real materials but are “equivalent” materials obtained from finite-difference modeling. (The thickness, conductivity, density and specific heat values of the material layers for the different constructions have been taken from the ASHRAE report “Modeling Two- and Three-Dimensional Heat Transfer through Composite Wall and Roof Assemblies in Hourly Energy Simulation Programs (1145-TRP),” by Enermodal Engineering Limited, Oak Ridge National Laboratory, and the Polish Academy of Sciences, January 2001.). EnergyPlus will calculate conduction transfer functions using these materials. The heat transfer based on these conduction transfer functions will then be very close to what would be calculated with a two- or three-dimensional heat transfer calculation.

For stud walls, using these composite constructions will give more accurate heat flow than you would get by manually dividing the wall into a stud section and a non-stud section.

If your wall’s exterior or interior roughness or thermal, solar or visible absorptances are different from those in the data set, you can make the appropriate changes to the first material (the outside layer) or the third material (the inside layer). **None of the other values should be changed.**

Complete description of the CompositeWallConstructions data set are found in the OutputDetailsAndExamples document.

### 1.8.51 Construction:ComplexFenestrationState

This input object is used to describe the properties of a single state for complex fenestration. There are two parts to the input, 1) layer-by-layer physical description of fenestration system and 2) a set of matrices that describe overall system optical performance. Each layer also has associated with it two matrices that give the layer absorptance (for front and back incidence on the system).

The optical properties are given as a two-dimensional matrix describing the basis and four two-dimensional matrices of system bidirectional optical properties.

These input objects will generally be exported directly from the WINDOW program and it is expected that users usually will not develop the input themselves. However, this is an option for users who prefer to use a different method (e.g., Monte-Carlo ray-trace or measurement) of determining optical properties.

Multiple instances of this object are used to define the separate operating states of complex fenestration. For example, blinds could be deployed or redirected to create a new state, or electrochromic glazings could change transmittance. Each separate state defines the materials present and the overall optical performance. If the glazing system has only one state, then only one of these objects is needed.

If there is more than one complex fenestration state, it will be controlled using the EMS actuator called “Surface” with the control type “Construction State” and the EMS input object called EnergyManagementSystem:ConstructionIndexVariable.

#### 1.8.51.1 Field: Name

Unique name of this construction. Used to identify type of window in surface objects.

#### 1.8.51.2 Field: Basis Type keyword

Only value currently implemented is “LBNLWINDOW”. More options may be added in the future.

#### 1.8.51.3 Field: Basis Symmetry, keyword

Only value currently implemented is “None”. More options will be added in the future.

#### 1.8.51.4 Field: Thermal Parameters

This field gives the name of WindowThermalModel:Params object used to keep common data necessary for thermal simulation.

#### 1.8.51.5 Field: Basis Matrix Name

This field gives the name of an  $2 \times N$  matrix object that defines the basis. For a fenestration basis,  $N$  would be the number of theta (polar angle) values, the first of the two elements for each of the  $i=1, \dots, N$  would be the theta value, and the second would be the number of phi (azimuthal angle) values that  $360^\circ$  is divided into for that theta.

#### 1.8.51.6 Field: Solar Optical Complex Front Transmittance Matrix Name

This field contains the name of matrix object that describes the solar transmittance at different incident angles. This is from the outside toward the inside.

#### 1.8.51.7 Field: Solar Optical Complex Back Reflectance Matrix Name

This field contains the name of matrix object that describes the solar back reflectance at different incident angles. This is from the inside toward the outside.

#### 1.8.51.8 Field: Visible Optical Complex Front Transmittance Matrix Name

This field contains the name of matrix object that describes the visible transmittance at different incident angles. This is from the outside toward the inside.

#### 1.8.51.9 Field: Visible Optical Complex Back Reflectance Matrix Name

This field contains the name of vector object that describes the visible back reflectance at different incident angles. This is from the inside toward the outside.

#### 1.8.51.10 Field: Outside Layer <x=1>

Each construction must have at least one layer. The layer order is from outside to inside, with the first layer being either WindowMaterial:Glazing or WindowMaterial:ComplexShade. The next layer is a WindowMaterial:Gap layer, and the following layers then alternate between WindowMaterial:Glazing or WindowMaterial:ComplexShade and WindowMaterial:Gap. The last layer cannot be WindowMaterial:Gap.

#### 1.8.51.11 Field: Outside Layer Directional Front Absorptance Matrix Name

Points to an  $N_{\text{basis}} \times 1$  matrix object.

#### 1.8.51.12 Field: Outside Layer Directional Back Absorptance Matrix Name

Points to an  $N_{\text{basis}} \times 1$  matrix object.

#### 1.8.51.13 Above 3 fields are optionally repeated for layers 2-10

These layers include gaps, which do not need to have matrix data specified.

An IDF example of complex fenestration with single layer:

```
Construction:ComplexFenestrationState,      !- single layer example
  CFS_Glz_1,                                !- name
  LBNLWindow,                               !- basis type
  None,                                     !- basis symmetry type
  ThermParam_1,                             !- window thermal model
  CFS_Glz_1_Basis,                          !- basis matrix name
  CFS_Glz_1_TfSol,                          !- TfSol
  CFS_Glz_1_RbSol,                          !- RbSol
  CFS_Glz_1_Tfvis,                           !- Tfvis
  CFS_Glz_1_Tbvis,                           !- Tbvis
  Glass_102_Layer,                           !- layer 1 name
  CFS_Glz_1_Layer_1_fAbs,                    !- fAbs
  CFS_Glz_1_Layer_1_bAbs;                    !- bAbs
```

An complex fenestration IDF example with double layer (first layer is shading device):

```
Construction:ComplexFenestrationState,      !- double layer example
  CFS_Glz_59,                                !- name
  LBNLWindow,                               !- basis type
  None,                                     !- basis symmetry type
  ThermParam_59,                             !- window thermal model
  CFS_Glz_59_Basis,                          !- basis matrix name
  CFS_Glz_59_TfSol,                          !- TfSol
  CFS_Glz_59_RbSol,                          !- RbSol
  CFS_Glz_59_Tfvis,                           !- Tfvis
  CFS_Glz_59_Tbvis,                           !- Tbvis
  Shade_30001_Layer,                          !- layer 1 name (shading device)
  CFS_Glz_59_Layer_1_fAbs,                    !- fAbs
  CFS_Glz_59_Layer_1_bAbs;                    !- bAbs
```

```

Gap_1_Layer,           !- layer 1 name
,                     !- absorptance matrices for gaps should be empty for now
,                     !- it is for future use
Glass_3110_Layer,     !- layer 2 name
CFS_Glz_59_Layer_3110_fAbs, !- fAbs
CFS_Glz_59_Layer_3110_bAbs; !- bAbs

```

### 1.8.52 WindowThermalModel:Params

This input object is used with the Construction:ComplexFenestrationState

#### 1.8.52.1 Field: Name

Unique name of the window thermal model parameters.

#### 1.8.52.2 Field: Calculation Standard

The type of the calculation standard. The choices are:

- ISO15099
- EN673Declared
- EN673Design

The default is ISO15099.

#### 1.8.52.3 Field: Thermal Model

The type of thermal model. The choices are:

- ISO15099
- ScaledCavityWidth
- ConvectiveScalarModel\_NoSDThickness
- ConvectiveScalarModel\_withSDThickness

The default is ISO15099.

#### 1.8.52.4 Field: SD Scalar

Shading Device Scalar Factor. Only used for Thermal Model = Convective Scalar Model. Factor of venetian shading device layer contribution to convection. Real value between 0 (where the shading device contribution to convection is neglected) and 1 (where the shading device treated as “closed” – as if it is a glass layer with thermal properties of SD slat material). Default: 1.0

#### 1.8.52.5 Field: Deflection Model

The type of deflection model used to model deflection in windows and glass. The choices are:

- NoDeflection
- TemperatureAndPressureInput
- MeasuredDeflection

The default is NoDeflection.

#### 1.8.52.6 Field: Vacuum Pressure Limit

The pressure (Pa) which will be considered to be the limit for vacuum glazing pressure. All pressures less than or equal to this pressure will be considered to be vacuum. Default: 13.238 Pa.

#### 1.8.52.7 Field: Initial Temperature

The temperature (°C) of the gap in the time of fabrication. It is used only when WindowThermalModel:Params DeflectionModel =TemperatureAndPressureInput

#### 1.8.52.8 Field: Initial Pressure

The pressure (Pa) of the gap at the time of fabrication of the sealed glazing system unitIt is used only when WindowThermalModel:Params DeflectionModel =TemperatureAndPressureInput.

An IDF example for WindowThermalModel:Params (without deflection):

```
WindowThermalModel:Params,
  ThermParam_59,           !- name
  ISO15099,                !- standard
  ISO15099,                !- thermal model standard
  1.00,                    !- SD scalar
  NoDeflection;           !- deflection model
```

An IDF example for thermal paramters (with deflection):

```
WindowThermalModel:Params,
  ThermParam_59,           !- name
  ISO15099,                !- standard
  ISO15099,                !- thermal model standard
  1.00,                    !- SD scalar
  TemperatureAndPressureInput, !- deflection model
  ,                        !- vacuum pressure limit
  21.00,                   !- temperature at time of fabrication
  10000.00;                !- pressure at time of fabrication
```

An IDF example for WindowThermalModel:Params for modeling vacuum glazing

```
WindowThermalModel:Params,
  ThermParam_1006,        !- name
  ISO15099,                !- standard
  ISO15099,                !- thermal model
  1.0000,                  !- SDScalar
  NoDeflection,           !- deflection model
  13.238;                  !- vacuum pressure limit
```

### 1.8.53 Matix:TwoDimension

This is input object is only used with Construction:ComplexFenestrationState object to enter a two-dimensional matrix of values.

It is used to define the Basis Matrix for BSDF input data, and is also used to define the actual BSDF matrices data for the complete fenestration definition as well as the individual layers of the system.

The data are entered in row-major order: all the elements of row 1, followed by all the elements of row 2, etc. The number of values to be entered depends on the number of rows and the number of columns. Blank fields are treated as having been set to zero.

See example IDF file "SmOff\_CmplxGlz\_IntExtShading.idf" for the definition of two complex shading layers with matrix data defined.

#### 1.8.53.1 Field: Name

Unique name of matrix input object.

#### 1.8.53.2 Field: Number of Rows

This field is the number of rows in the matrix.

#### 1.8.53.3 Field: Number of Columns

This field is the number of columns in the matrix

#### 1.8.53.4 < Field Set: Value # N >

Repeat entering value exactly the same number of times as the number of rows times the number of columns.

#### 1.8.53.5 Field: Value # 1

This is the value of the matrix at the first row and first column.

#### 1.8.53.6 Field: Value #2

This is the value of the matrix at the first row and the second column.

An IDF example of matrix for defining BSDF basis:

```
Matrix:TwoDimension,      !- matrix for basis definition
  CFS_Glz_1_Basis,        !- basis matrix name
  9,                       !- number of rows
  2,                       !- number of columns
  0.00000, 1.00000,
  10.00000, 8.00000,
```

```

20.00000, 16.00000,
30.00000, 20.00000,
40.00000, 24.00000,
50.00000, 24.00000,
60.00000, 24.00000,
70.00000, 16.00000,
82.50000, 12.00000;

```

### 1.8.54 Construction:WindowEquivalentLayer

This object defines the construction for equivalent layer window (ASHWAT) model. This window can model various mix of glazing and shading layers combination. Shadings are defined as an integral part of the construction. The construction is defined by listing the layers name starting with outside layer and work your way to the inside Layer. Up to six solid layers (glazing and shade) and up to five gaps, i.e., a total of up to 11 layers maximum are allowed in equivalent layer window object. The solid layer types allowed are: Glazing, Insect Screen, Roller Blinds, Venetian Blind, and Drape Fabrics. This window model requires optical data of the individual glazing and shading layers to calculate the effective optical properties of the composite fenestration construction. Venetian blinds in equivalent layer window model can be in a fixed slat angle or has the option to control the slat angle in order to maximize visibility, or maximize solar gains. An equivalent-layer concept can simulate wide range of multiple glazing and shading layers combination and provides unlimited flexibility to combine different types of shading layers in a fenestration. For the gap layer object any one of the five different Gas types can be specified: AIR, ARGON, XENON, KRYPTON, or CUSTOM. This window object is referenced by fenestration surfaces. For details of the model description refer to Equivalent Layer Fenestration Model section in Engineering Reference. The various layer objects that can be referenced in Equivalent Layer window model are:

WindowMaterial:Glass:EquivalentLayer

WindowMaterial:Shade:EquivalentLayer

WindowMaterial:Drape:EquivalentLayer

WindowMaterial:Blind:EquivalentLayer

WindowMaterial:Screen:EquivalentLayer

WindowMaterial:Gap:EquivalentLayer

#### 1.8.54.1 Field: Name

This field is a user specified name that will be used as a reference by other input syntax. For example, a heat transfer surface (ref: Fenestration) requires a construction name to define what the make-up of the fenestration is. This name must be identical to one of the Window Construction Equivalent Layer definitions in the input data file.

#### 1.8.54.2 Field: Outside Layer

Each equivalent layer window construction must have at least one layer. This field defines the material name associated with the layer on the outside of the construction—outside referring to the side that is exposed to the outdoor environment or another zone. Material layers for equivalent layer window model are defined based on their thermal properties elsewhere in the input file (ref: WindowEquivalentLayerMaterialNames)

#### 1.8.54.3 Field: Layer 2 - Layer11

The next fields are optional and the number of them showing up in a particular equivalent layer window construction definition depends solely on the number of material layers present in that construction. The data expected is identical to the outside layer field (see previous field description). The order of the remaining layers is important and should be listed in order of occurrence from the one just inside the outside layer until the inside layer is reached. As noted above, the inside layer should NOT be a film coefficient since EnergyPlus will calculate inside convection and radiation heat transfer more precisely.

An IDF example for this object, is shown below:

```

Construction:WindowEquivalentLayer,
Six Solid Layers Window,      !- Name
INSCRN,                       !- Outside Layer
Air GAP Outdoor 12.7mm,      !- Layer 2
GLZGRY,                       !- Layer 3
Argon GAP Sealed 12.7mm,    !- Layer 4
FEP,                          !- Layer 5
Xenon GAP Sealed 12.7mm,    !- Layer 6
LOF1436,                     !- Layer 7
Krypton GAP Sealed 12.7mm,  !- Layer 8
GLZCLR,                      !- Layer 9
Air GAP Indoor 12.7mm,      !- Layer 10
ShadeTrns;                   !- Layer 11

```

### 1.8.55 Construction:WindowDataFile

The WINDOW program, which does a thermal and optical analysis of a window under different design conditions, writes a data file ("Window data file") containing a description of the window that was analyzed. The Construction:WindowDataFile object allows a window to be read in from the WINDOW data file—see

“Importing Windows from WINDOW.” For information on adding a shading device to the window see “WindowProperty:ShadingControl.”

### 1.8.55.1 Field: Name

This is the name of a window on the Window data file. An error will result if EnergyPlus cannot find a window of this name on the file, or if the file, shown in the next field, is not present. The location of the data file should be specified in the File Name field. For details on what is done with the data if a matching window is found on the file see “Importing Windows from WINDOW.”

### 1.8.55.2 Field: File Name

This is the file name of the Window data file that contains the Window referenced in the previous field. The field may include a full path with file name, for precise results. The field must be <= 100 characters. The file name must not include commas or an exclamation point. A relative path or a simple file name should work with version 7.0 or later when using EP-Launch even though EP-Launch uses temporary directories as part of the execution of EnergyPlus. If using RunEPlus.bat to run EnergyPlus from the command line, a relative path or a simple file name may work if RunEPlus.bat is run from the folder that contains EnergyPlus.exe.

If this field is left blank, the file name is defaulted to Window5DataFile.dat.

#### Input Example

```
Construction:WindowDataFile,  
  DoubleClear;           !- Name of a Window on the Window Data File
```

**! Note – Window5DataFile.dat is presumed to be in the “run” folder where EnergyPlus.exe is**

```
FenestrationSurface:Detailed,  
  Zn001:Wall001:Win001, !- Name  
  Window,               !- Class  
  DoubleClear,         !- Construction Name  
  Zn001:Wall001,,      !- Base Surface Name, and Target (if applicable)  
  0.5,                 !- View Factor to Ground  
  ,                   !- Window Shading Control name  
  ,                   !- Frame/Divider name  
  1.0,                !- Multiplier  
  4,                  !- Number of vertices  
  0.548, 0.0, 2.5000, !- X,Y,Z of Vertices  
  0.548, 0.0, 0.5000,  
  5.548, 0.0, 0.5000,  
  5.548, 0.0, 2.5000;
```

An example showing use of specific data file name and complete path location follows:

```
Construction:WindowDataFile,  
  DoubleClear,         !- Name of a Window on the Window Data File
```

**C:\EnergyPlusData\DataSets\MyWindow.dat;**

## 1.8.56 Construction Element Outputs

An optional report (contained in **eplusout.eio**) gives calculational elements for the materials and constructions used in the input. These reports are explained fully in the Output Details and Examples document.

## 1.9 Group – Thermal Zone Description/Geometry

Without thermal zones and surfaces, the building can't be simulated. This group of objects (Zone, BuildingSurface) describes the thermal zone characteristics as well as the details of each surface to be modeled. Included here are shading surfaces.

### 1.9.1 Zone

This element sets up the parameters to simulate each thermal zone of the building.

#### 1.9.1.1 Field: Direction of Relative North

The Zone North Axis is specified **relative to the Building North Axis**. This value is specified in degrees (clockwise is positive). For more information, see the figure below as well as the description under “GlobalGeometryRules”.

#### 1.9.1.2 Field(s): (X,Y,Z) Origin

The X,Y,Z coordinates of a zone origin can be specified, for convenience in vertice entry. Depending on the values in “GlobalGeometryRules” (see description later in this section), these will be used to completely specify the building coordinates in “world coordinate” or not. Zone Origin coordinates are specified **relative to the Building Origin (which always 0,0,0)**. The following figure illustrates the use of Zone North Axis as well as Zone Origin values.

Figure 27. Illustration of Zone North Axis and Origins

### 1.9.1.3 Field: Type

Zone type is currently unused.

### 1.9.1.4 Field: Multiplier

Zone Multiplier is designed as a “multiplier” for floor area, zone loads, and energy consumed by internal gains. It takes the calculated load for the zone and multiplies it, sending the multiplied load to the attached HVAC system. The HVAC system size is specified to meet the entire multiplied zone load and will report the amount of the load met in the Zone Air System Sensible Heating or Cooling Energy/Rate output variable. Autosizing automatically accounts for multipliers. Metered energy consumption by internal gains objects such as Lights or Electric Equipment will be multiplied. The default is 1.

### 1.9.1.5 Field: Ceiling Height

Zone ceiling height is used in several areas within EnergyPlus (such as various room models, some convection coefficient calculations and, primarily, in calculating zone volume in the absence of other parameters). Energyplus automatically calculates the zone ceiling height (m) from the average height of the zone. If this field is 0.0, negative or **autocalculate**, then the calculated zone ceiling height will be used in subsequent calculations. If this field is positive, then the calculated zone ceiling height will not be used -- the number entered here will be used as the zone ceiling height. If this number differs significantly from the calculated ceiling height, then a warning message will be issued. If a zone ceiling height is entered, but no Volume is entered, then the floor area (if there is one) times the zone ceiling height will be used as the volume.

Note that the Zone Ceiling Height is the distance from the Floor to the Ceiling in the Zone, not an absolute height from the ground.

### 1.9.1.6 Field: Volume

Zone volume is used in several areas within EnergyPlus (such as calculating air change rates for reporting or flow when air change rates are chosen as input, daylighting calculations, some convection coefficient calculations). EnergyPlus automatically calculates the zone volume (m<sup>3</sup>) from the zone geometry given by the surfaces that belong to the zone. If this field is 0.0, negative or **autocalculate**, then the calculated zone volume will be used in subsequent calculations. If this field is positive, then it will be used as the zone volume. If this number differs significantly from the calculated zone volume a warning message will be issued. For autocalculate to work properly, the zone must be enclosed by the entered walls. Note that indicating the volume to be calculated but entering a positive ceiling height in the previous field will cause the volume to be calculated as the floor area (if > 0) times the entered ceiling height; else the volume will be calculated from the described surfaces. If this field is positive, any ceiling height positive value will not be used in volume calculations.

### 1.9.1.7 Field: Floor Area

Zone floor area is used in many places within EnergyPlus. EnergyPlus automatically calculates the zone floor area (m<sup>2</sup>) from the zone geometry given by the surfaces that belong to the zone. If this field is 0.0, negative or **autocalculate**, then the calculated zone floor area will be used in subsequent calculations. If this field is positive, then it will be used as the zone floor area. If this number differs significantly from the calculated zone floor area a warning message will be issued.

### 1.9.1.8 Field: Zone Inside Convection Algorithm

The Zone Inside Convection Algorithm field is optional. This field specifies the convection model to be used for the inside face of heat transfer surfaces associated with this zone. The choices are: **Simple** (constant natural convection - ASHRAE), **Detailed** (variable natural convection based on temperature difference - ASHRAE), **CeilingDiffuser** (ACH based forced and mixed convection correlations for ceiling diffuser configuration with simple natural convection limit), **AdaptiveConvectionAlgorithm** (complex arrangement of various models that adapt to various zone conditions and can be customized) and **TrombeWall** (variable natural convection in an enclosed rectangular cavity). See the Inside Convection Algorithm object for further descriptions of the available models.

If omitted or blank, the algorithm specified in the SurfaceConvectionAlgorithm:Inside object is the default.

### 1.9.1.9 Field: Zone Outside Convection Algorithm

The Zone Outside Convection Algorithm field is optional. This field specifies the convection model to be used for the outside face of heat transfer surfaces associated with this zone. The choices are: **SimpleCombined**, **TARP**, **DOE-2**, **MoWITT**, and **AdaptiveConvectionAlgorithm**. The simple convection model applies heat transfer coefficients depending on the roughness and windspeed. This is a combined heat transfer coefficient that includes radiation to sky, ground, and air. The correlation is based on Figure 1, Page 25.1 (Thermal and Water Vapor Transmission Data), 2001 ASHRAE Handbook of Fundamentals.

The other convection models apply heat transfer coefficients depending on the roughness, windspeed, and terrain of the building's location. These are *convection only* heat transfer coefficients; radiation heat transfer coefficients are calculated automatically by the program. The TARP algorithm was developed for the TARP software and combines natural and wind-driven convection correlations from laboratory measurements on flat plates. The DOE-2 and MoWITT were derived from field measurements. The AdaptiveConvectionAlgorithm model is a dynamic algorithm that organizes a large number of different convection models and automatically selects the one that best applies. The adaptive convection algorithm can also be customized using the SurfaceConvectionAlgorithm:Outside:AdaptiveModelSelections input object. All algorithms are described more fully in the Engineering Reference.

If omitted or blank, the algorithm specified in the SurfaceConvectionAlgorithm:Outside object is the default.

#### 1.9.1.10 Field: Part of Total Floor Area

This optional field defaults to Yes if not specified. The field is used to show when a zone is not part of the Total Floor Area as shown in the Annual Building Utility Performance Summary tables. Specifically, when No is specified, the area is excluded from both the conditioned floor area and the total floor area in the Building Area sub table and the Normalized Metrics sub tables.

And, an IDF example:

```
Zone,
  DORM ROOMS AND COMMON AREAS,  !- Name
  0.0000000E+00,                !- Direction of Relative North {deg}
  0.0000000E+00,                !- X Origin {m}
  6.096000,                     !- Y Origin {m}
  0.0000000E+00,                !- Z Origin {m}
  1,                             !- Type
  1,                             !- Multiplier
  autocalculate,                !- Ceiling Height {m}
  autocalculate;                !- Volume {m3}
```

### 1.9.2 Zone Outputs

- Zone,Average,Zone Outdoor Air Drybulb Temperature [C]
- Zone,Average,Zone Outdoor Air Wetbulb Temperature [C]
- Zone,Average,Zone Outdoor Air Wind Speed [m/s]

#### 1.9.2.1 Zone Outdoor Air Drybulb Temperature [C]

The outdoor air dry-bulb temperature calculated at the height above ground of the zone centroid.

#### 1.9.2.2 Zone Outdoor Air Wetbulb Temperature [C]

The outdoor air wet-bulb temperature calculated at the height above ground of the zone centroid.

#### 1.9.2.3 Zone Outdoor Air Wind Speed [m/s]

The outdoor wind speed calculated at the height above ground of the zone centroid.

### 1.9.3 Zone Thermal Output(s)

In addition to the canned Surface reports (view the Reports section later in this document) and surface variables (above), the following variables are available for all zones:

- Zone,Sum,Zone Total Internal Radiant Heating Energy [J]
- Zone,Average,Zone Total Internal Radiant Heating Rate [W]
- Zone,Sum,Zone Total Internal Visible Radiation Heating Energy [J]
- Zone,Average,Zone Total Internal Visible Radiation Heating Rate [W]
- Zone,Sum,Zone Total Internal Convective Heating Energy [J]
- Zone,Average,Zone Total Internal Convective Heating Rate [W]
- Zone,Sum,Zone Total Internal Latent Gain Energy [J]

- Zone,Average,Zone Total Internal Latent Gain Rate [W]
- Zone,Sum,Zone Total Internal Total Heating Energy [J]
- Zone,Average,Zone Total Internal Total Heating Rate [W]
- Zone,Average,Zone Mean Air Temperature [C]
- HVAC,Average,Zone Air Temperature [C]
- Zone,Average,Zone Mean Air Dewpoint Temperature [C]
- Zone,Average,Zone Mean Radiant Temperature [C]
- Zone,Average,Zone Operative Temperature [C]
- HVAC,Average,Zone Air Heat Balance Internal Convective Heat Gain Rate [W]
- HVAC,Average,Zone Air Heat Balance Surface Convection Rate [W]
- HVAC,Average,Zone Air Heat Balance Interzone Air Transfer Rate [W]
- HVAC,Average,Zone Air Heat Balance Outdoor Air Transfer Rate [W]
- HVAC,Average,Zone Air Heat Balance System Air Transfer Rate [W]
- HVAC,Average,Zone Air Heat Balance System Convective Heat Gain Rate [W]
- HVAC,Average,Zone Air Heat Balance Air Energy Storage Rate [W]
- HVAC,Average,Zone Air Heat Balance Deviation Rate [W]
- HVAC,Sum,Zone Air System Sensible Heating Energy [J]
- HVAC,Sum,Zone Air System Sensible Cooling Energy [J]
- HVAC,Average,Zone Air System Sensible Heating Rate [W]
- HVAC,Average,Zone Air System Sensible Cooling Rate [W]
- HVAC,Average,Zone Air Humidity Ratio[kgWater/kgDryAir]
- HVAC,Average,Zone Air Relative Humidity[%]

Two of these are of particular interest:

Zone,Average,Zone Mean Air Temperature [C]

HVAC,Average,Zone Air Temperature [C]

These two variable outputs are/should be identical. However, note that they can be reported at different time intervals. “Zone Mean Air Temperature” is only available on the Zone/HB timestep (Number of Timesteps per Hour) whereas “Zone Air Temperature” can be reported at the HVAC timestep (which can vary).

#### **1.9.3.1 Zone Mean Air Temperature [C]**

From the code definition, the zone mean air temperature is the average temperature of the air temperatures at the system timestep. Remember that the zone heat balance represents a “well stirred” model for a zone, therefore there is only one mean air temperature to represent the air temperature for the zone.

#### **1.9.3.2 Zone Air Temperature [C]**

This is very similar to the mean air temperature in the last field. The “well stirred” model for the zone is the basis, but this temperature is also available at the “detailed” system timestep.

#### **1.9.3.3 Zone Mean Air Dewpoint Temperature [C]**

This is the dewpoint temperature of the zone calculated from the Zone Mean Air Temperature (above), the Zone Air Humidity Ratio (below) and the outdoor barometric pressure.

#### **1.9.3.4 Zone Thermostat Air Temperature [C]**

This is the zone air node temperature for the well-mixed room air model, which is the default room air model type (RoomAirModelType=Mixing). But for other types of Room Air Model (the RoomAir:TemperaturePattern:\* and RoomAirSettings:\* objects) the zone thermostat air temperature may depend on the Thermostat Height and Thermostat Offset.

### 1.9.3.5 Zone Mean Radiant Temperature [C]

The Mean Radiant Temperature (MRT) in degrees Celsius of a space is a measure of the combined effects of temperatures of surfaces within that space. Specifically it is the surface area × emissivity weighted average of the zone inside surface temperatures (ref. Surface Inside Temperature), where emissivity is the Thermal Absorptance of the inside material layer of each surface.

### 1.9.3.6 Zone Operative Temperature [C]

Zone Operative Temperature (OT) is the average of the Zone Mean Air Temperature (MAT) and Zone Mean Radiant Temperature (MRT),  $OT = 0.5 \cdot MAT + 0.5 \cdot MRT$ . This output variable is not affected by the type of thermostat controls in the zone, and does not include the direct effect of high temperature radiant systems. See also Zone Thermostat Operative Temperature.

### 1.9.3.7 Zone Air Heat Balance Internal Convective Heat Gain Rate [W]

The Zone Air Heat Balance Internal Convective Heat Gain Rate is the sum, in watts, of heat transferred to the zone air from all types of internal gains, including people, lights, equipment etc. This and the following provide results on the load components of the zone air heat balance. This field is not multiplied by zone or group multipliers.

### 1.9.3.8 Zone Air Heat Balance Surface Convection Rate [W]

The Zone Air Heat Balance Surface Convection Rate is the sum, in watts, of heat transferred to the zone air from all the surfaces. This field is not multiplied by zone or group multipliers.

### 1.9.3.9 Zone Air Heat Balance Interzone Air Transfer Rate [W]

The Zone Air Heat Balance Interzone Air Transfer Rate is the sum, in watts, of heat transferred to the zone air from all the transfers of air from other thermal zones. This field is not multiplied by zone or group multipliers.

### 1.9.3.10 Zone Air Heat Balance Outdoor Air Transfer Rate [W]

The Zone Air Heat Balance Outdoor Air Transfer Rate is the sum, in watts, of heat transferred to the zone air from all the transfers of air from the out side, such as infiltration. This field is not multiplied by zone or group multipliers.

### 1.9.3.11 Zone Air Heat Balance System Air Transfer Rate [W]

The Zone Air Heat Balance System Air Transfer Rate is the sum, in watts, of heat transferred to the zone air by HVAC forced-air systems and air terminal units. Such HVAC systems are connected to the zone by an inlet node (see ZoneHVAc:EquipmentConnections input field called Zone Air Inlet Node or Node List Name) This field is not multiplied by zone or group multipliers.

### 1.9.3.12 Zone Air Heat Balance System Convective Heat Gain Rate [W]

The Zone Air Heat Balance System Convective Heat Gain Rate is the sum, in watts, of heat transferred directly to the zone air by “non-air” HVAC systems. Such HVAC systems are not connected to the zone by an inlet node but rather add or subtract heat directly to the zone air in a manner similar to internal gains. These include the convective fraction of zone HVAC baseboards and high temperature radiant systems, zone HVAC refrigeration chiller set, and the extra convective cooling provided by the cooled beam air terminal unit. This field is not multiplied by zone or group multipliers.

### 1.9.3.13 Zone Air Heat Balance Air Energy Storage Rate [W]

The Zone Air Heat Balance Air Energy Storage Rate is the heat stored, in watts, in the zone air as result of zone air temperature changing from one timestep to the next. This field is not multiplied by zone or group multipliers.

### 1.9.3.14 Zone Air Heat Balance Deviation Rate [W]

The Zone Air Heat Balance Deviation Rate is the imbalance, in watts, in the energy balance for zone air. The value should be near zero but will become non-zero if zone conditions are changing rapidly or erratically. This field is not multiplied by zone or group multipliers. (This output variable is only generated if the user has set a computer system environment variable DisplayAdvancedReportVariables equal to “yes”.)

### 1.9.3.15 Zone Air System Sensible Heating Energy [J]

This output variable represents the sensible heating energy in Joules that is actually supplied by the system to that zone for the timestep reported. This is the sensible heating rate multiplied by the simulation timestep. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. . This field is not multiplied by zone or group multipliers.

Zone Air System Sensible Heating (and Cooling) Energy (and Rate) all report the heating or cooling delivered by the HVAC system to a zone. These values are calculated by multiplying the supply air mass flow rate by the difference between the supply air temperature and the zone air temperature. This does not always indicate the operation of heating or cooling coils. For example, cooling will be reported if the supply air is cooled due to the introduction of outside air, even if all coils are off.

Note that these variables are calculated at the system timestep. When reported at the "detailed" reporting frequency, these variable will never show heating and cooling both in the same system timestep. If reported at a frequency less than "Detailed" (for example, Hourly) values may appear in both the heating and cooling variable for the same hour if the system cooled the zone for part of the reporting period and heated the zone for another part of the reporting period.

#### **1.9.3.16 Zone Air System Sensible Cooling Energy [J]**

This output variable represents the sensible cooling energy in Joules that is actually supplied by the system to that zone for the timestep reported. This is the sensible cooling rate multiplied by the simulation timestep. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers.

#### **1.9.3.17 Zone Air System Sensible Heating Rate [W]**

This output variable represents the sensible heating rate in Watts that is actually supplied by the system to that zone for the timestep reported. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers.

#### **1.9.3.18 Zone Air System Sensible Cooling Rate [W]**

This output variable represents the sensible cooling rate in Watts that is actually supplied by the system to that zone for the timestep reported. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers.

#### **1.9.3.19 Zone Air Humidity Ratio [kgWater/kgDryAir]**

This output variable represents the air humidity ratio after the correct step for each zone. The humidity ratio is the mass of water vapor to the mass of dry air contained in the zone in (kg water/kg air) and is unitless.

#### **1.9.3.20 Zone Air Relative Humidity [%]**

This output variable represents the air relative humidity after the correct step for each zone. The relative humidity is in percent and uses the Zone Air Temperature, the Zone Air Humidity Ratio and the Outside Barometric Pressure for calculation.

#### **1.9.3.21 Zone Total Internal Radiant Heating Rate [W]**

#### **1.9.3.22 Zone Total Internal Radiant Heating Energy [J]**

These output variables represent the sum of radiant gains from specific internal sources (e.g. equipment) throughout the zone in Watts (for rate) or joules. This includes radiant gain from People, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

#### **1.9.3.23 Zone Total Internal Visible Radiation Heating Rate [W]**

#### **1.9.3.24 Zone Total Internal Visible Radiation Heating Energy [J]**

These output variables express the sum of heat gain in Watts (for rate) or joules that is the calculated short wavelength radiation gain from lights in the zones. This calculation uses the total energy from lights and the fraction visible to realize this value, summed over the zones in the simulation.

#### **1.9.3.25 Zone Total Internal Convective Heating Rate [W]**

#### **1.9.3.26 Zone Total Internal Convective Heating Energy [J]**

These output variables represent the sum of convective gains from specific sources (e.g. equipment) throughout the zone in Watts (for rate) or joules. This includes convective gain from People, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

#### **1.9.3.27 Zone Total Internal Latent Gain Rate [W]**

#### **1.9.3.28 Zone Total Internal Latent Gain Energy [J]**

These output variables represent the sum of latent gains from specific internal sources (e.g. equipment) throughout the zone in Watts (for rate) or joules. This includes latent gain from People, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

#### **1.9.3.29 Zone Total Internal Total Heating Rate [W]**

#### **1.9.3.30 Zone Total Internal Total Heating Energy [J]**

These output variables represent the sum of all heat gains throughout the zone in Watts (for rate) or joules. This includes all heat gains from People, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

### **1.9.4 ZoneList**

The ZoneList object defines a list of Zone objects. It is primarily used with the ZoneGroup object to provide a generalized way for doing "Floor Multipliers". (See the ZoneGroup description below.) The associated ZoneList output variables also provide a way to aggregate and organize zone loads.

Zone lists are not exclusive. A zone can be referenced by more than one ZoneList object.

#### 1.9.4.1 Field: Zone List Name

The name of the ZoneList object. Must be unique across ZoneLists.

#### 1.9.4.2 Field: Zone 1 – 20 Name

Reference to a Zone object. This field is extensible; for greater than 20 zones, edit the IDD to add more *Zone Name* fields.

```
Zidf oneList, Mid Floor List, !- Name Mid West Zone, !- Zone 1 Name Mid Center Zone, !- Zone 2 Name Mid East
```

### 1.9.5 ZoneList Outputs

The following output variables are reported by the ZoneList object:

- HVAC,Average,Zone List Sensible Heating Rate [W]
- HVAC,Average,Zone List Sensible Cooling Rate [W]
- HVAC,Sum,Zone List Sensible Heating Energy [J]
- HVAC,Sum,Zone List Sensible Cooling Energy [J]

All ZoneList variables are the sum of the corresponding Zone variables. *Zone Multiplier* fields in the Zone objects are also taken into account.

### 1.9.6 ZoneGroup

The ZoneGroup object adds a multiplier to a ZoneList. This can be used to reduce the amount of input necessary for simulating repetitive structures, such as the identical floors of a multi-story building. To create a "Floor Multiplier", use the ZoneList object to organize several zones into a typical floor. Then use the *Zone List Multiplier* field in the ZoneGroup object to multiply the system load for the zones in the list will also be multiplied. Zones with *Multiplier* field greater than one in the Zone object are effectively double-multiplied.

NOTE: Although ZoneLists are not exclusive by themselves, ZoneLists used to form a ZoneGroup are exclusive; the ZoneLists used with a ZoneGroup must not have any zones in common.

#### 1.9.6.1 Tips for Multi-Story Simulations:

- For floors that are multiplied, connect exterior boundary conditions of the floor to the ceiling and vice versa.
- Since exterior convection coefficients vary with elevation, locate the typical middle floor zones midheight between the lowest and highest middle floors to be modeled.
- Shading must be identical for all multiplied floors or less accurate results may be obtained by using the zone list multiplier.

ZoneGroup and ZoneList can also be used to simulate other repetitive cases, such as clusters of zones on the ground.

#### 1.9.6.2 Field: Zone Group Name

The name of the ZoneGroup object. This must be unique across ZoneGroups.

#### 1.9.6.3 Field: Zone List Name

Reference to a ZoneList object. The zones in the list constitute the zones in the group.

#### 1.9.6.4 Field: Zone List Multiplier

An integer multiplier. Zone List Multiplier is designed as a "multiplier" for floor area, zone loads, and energy consumed by internal gains. It takes the calculated load for the zone and multiplies it, sending the multiplied load to the attached HVAC system. The HVAC system size is specified to meet the entire multiplied zone load and will report the amount of the load met in the Zone Air System Sensible Heating or Cooling Energy/Rate output variable. Autosizing automatically accounts for multipliers. Metered energy consumption by internal gains objects such as Lights or Electric Equipment will be multiplied. The default is 1.

```
ZONE GROUP,  
  Mid Floor, !- Zone Group Name  
  Mid Floor List, !- Zone List Name  
  8; !- Zone List Multiplier
```

### 1.9.7 ZoneGroup Outputs

The following output variables are reported by the ZoneGroup object:

- HVAC,Average,Zone Group Sensible Heating Rate [W]
- HVAC,Average,Zone Group Sensible Cooling Rate [W]
- HVAC,Sum,Zone Group Sensible Heating Energy [J]
- HVAC,Sum,Zone Group Sensible Cooling Energy [J]

All ZoneGroup variables report the associated ZoneList value multiplied by the *Zone List Multiplier*.

### 1.9.8 Surface(s)

What's a building without surfaces?

EnergyPlus allows for several surface types:

- **BuildingSurface:Detailed**
- **FenestrationSurface:Detailed**
- **Shading:Site:Detailed**
- **Shading:Building:Detailed**
- **Shading:Zone:Detailed**

Each of the preceding surfaces has “correct” geometry specifications. BuildingSurface and Fenestration surfaces (heat transfer surfaces) are used to describe the important elements of the building (walls, roofs, floors, windows, doors) that will determine the interactions of the building surfaces with the outside environment parameters and the internal space requirements. These surfaces are also used to represent “interzone” heat transfer. During specification of surfaces, several “outside” environments may be chosen:

- **Ground** – when the surface is in touch with the ground (e.g. slab floors)
- **Outdoors** – when the surface is an external surface (e.g. walls, roofs, windows directly exposed to the outdoor conditions)
- **Surface** – when the surface is
  - An adiabatic internal zone surface
  - A interzone surface
- **Zone** – when the surface is
  - A interzone surface in which the other surface is not put in the input file.
- **OtherSideCoefficients** – when using a custom profile to describe the external conditions of the surface (advanced concept – covered in subject: SurfaceProperty:OtherSideCoefficients)
- **OtherSideConditionsModel** – when using specially modeled components, such as active solar systems, that cover the outside surface and modify the conditions it experiences.

**Surface** items must also specify an “outside face object”. This is

- Current surface name – for adiabatic internal surfaces.
- A surface name in another zone – for interzone heat transfer.
- An “opposing” surface name (in the current zone) – for representing “middle” zones.

**Zone** items must also specify an “outside face object”. This is

- The zone that contains the other surface that is adjacent to this surface but is not entered in input.

Note that heat transfer surfaces are fully represented with each description. As stated earlier in the Construction description, materials in the construction (outside to inside) are included but film coefficients neither inside nor outside are used in the description – these are automatically calculated during the EnergyPlus run. Interzone surfaces which do not have a symmetrical construction (such as a ceiling/floor) require two Construction objects with the layers in reverse order. For example, CEILING with carpet, concrete, ceiling tile and FLOOR with ceiling tile, concrete, carpet. If interzone surfaces have a symmetrical construction, the specification for the two surfaces can reference the same Construction.

**Shading** surfaces are used to describe aspects of the site which do not directly impact the physical interactions of the environmental parameters but may significantly shade the building during specific hours of the day or time so the year (e.g. trees, bushes, mountains, nearby buildings which aren't being simulated

as part of this facility, etc.)

Note that surfaces which are part of the simulated building automatically shade other parts of the building as geometry and time of day dictate – there is no need on the user's part to include surfaces that might be in other zones for shading.

Another surface type:

- **InternalMass**

is used to specify the construction/material parameters and area of items within the space that are important to heat transfer calculations but not necessarily important geometrically. (For example, furniture within the space – particularly for large spaces). Internal mass can also be used for internal walls that are not needed (when FullInteriorAndExterior Solar Distribution is in effect) for solar distribution or to represent many, if not all, interior walls when solar is distributed to the floors only.

### 1.9.9 Interzone Surfaces

EnergyPlus can quite accurately simulate the surface heat exchange between two zones. However, this accuracy is not always required and using interzonal heat transfer does add to the complexity of the calculations – thus requiring more CPU time to simulate. More information about interzonal heat transfer calculations is contained in the Engineering Reference. Some simple guidelines are presented here – for three cases: adiabatic surfaces, surfaces in “middle” zones, and surfaces where heat transfer is “expected” (e.g. between a residence and an unheated, attached garage).

- **Adiabatic Surfaces** – These surfaces would be represented as common surfaces (between two zones) where both zones are typically the same temperature. Thus, no transfer is expected in the surface from one zone to the next. These surfaces should be described as simply internal surfaces for the zone referencing as their Outside Boundary Condition Object (see later description in individual surface objects) their own surface names.
- **Surfaces in Middle Zones** – Middle zones in a building can be simulated using a judicious use of surfaces and zone multipliers to effect the correct “loads” for the building. Thus, middle zone behavior can be simulated without modeling the adjacent zones. This is done by specifying a surface within the zone. For example, a middle floor zone can be modeled by making the floor the Outside Boundary Condition Object for the ceiling, and the ceiling the Outside Boundary Condition Object for the floor.
- **Surfaces between Zones with differing temperatures** – These zones represent the true use of interzone surfaces. In a residence that has an attached garage, the garage may be unheated/uncooled or at least not conditioned to the same degree as the residence interior. In this case, EnergyPlus can be used to accurately calculate the effects of the differently conditioned space to the other spaces.

### 1.9.10 Surface View Factors

EnergyPlus uses an area weighted approximation to calculate “view factors” between surfaces within a thermal zone. Each surface uses the total area that it can “see” among the other surfaces. The approximate view factor from this surface to each other surface is then the area of the receiving surface over the sum of areas that is visible to the sending surface.

In order to account in some limited way for the fact that certain surfaces will not see each other, several assumptions have been built into this simple view factor approximation. First, a surface cannot see itself. Second, surfaces with approximately the same azimuth (facing direction) and tilt (“same” being within a built in limit) will not see each other. This means that a window will not see the wall that it is placed on, for example. Third, floors cannot see each other. Fourth, if the surface is a floor, ceiling, roof, or internal mass, the rule for the same azimuth and tilt eliminating radiant exchange between surface is waived when the receiving surface is floor, roof, ceiling, or internal mass as long as both surfaces are not floors.

Note that this does not take into account that surfaces may be “around the corner” from each other and in reality not see each other at all. Rooms are assumed to be convex rather than concave in this method.

To summarize, using the Surface “Class”, the approximate view factors have:

1. No surface sees itself.
2. No Floor sees another floor.
3. All other surface types see Internal Mass.
4. All other surface types see floors.
5. Floors always see ceilings.
6. Floors always see roofs.
7. All other surfaces whose tilt or facing angle differences are greater than 10 degrees see each other.

If geometry is correct, conditions 1,3, and 7 should take care of all surfaces, but the other conditions supply common sense when the geometry is incorrect. More information about the EnergyPlus view factor calculation is contained in the Engineering Reference document.

### 1.9.11 GlobalGeometryRules

Before the surface objects are explained in detail, a description of geometric parameters used in EnergyPlus will be given. Since the input of surface vertices is common to most of the surface types, it will also be given a separate discussion.

Some flexibility is allowed in specifying surface vertices. This flexibility is embodied in the GlobalGeometryRules class/object in the input file. Note that the parameters specified in this statement are used for all surface vertex inputs – there is no further “flexibility” allowed.

In order to perform shadowing calculations, the building surfaces must be specified. EnergyPlus uses a three dimensional (3D) Cartesian coordinate system for surface vertex specification. This Right Hand coordinate system has the X-axis pointing east, the Y-axis pointing north, and the Z-axis pointing up. See figure below.

Figure 28. EnergyPlus Coordinate System

#### 1.9.11.1 Field: Starting Vertex Position

The shadowing algorithms in EnergyPlus rely on surfaces having vertices in a certain order and positional structure. Thus, the surface translator needs to know the starting point for each surface entry. The choices are: UpperLeftCorner, LowerLeftCorner, UpperRightCorner, or LowerRightCorner. Since most surfaces will be 4 sided, the convention will specify this position as though each surface were 4 sided. Extrapolate 3 sided figures to this convention. For 5 and more sided figures, again, try to extrapolate the best “corner” starting position.

#### 1.9.11.2 Field: Vertex Entry Direction

Surfaces are always specified as being viewed from the outside of the zone to which they belong. (Shading surfaces are specified slightly differently and are discussed under the particular types). EnergyPlus needs to know whether the surfaces are being specified in counterclockwise or clockwise order (from the Starting Vertex Position). EnergyPlus uses this to determine the outward facing normal for the surface (which is the *facing angle* of the surface – very important in shading and shadowing calculations).

#### 1.9.11.3 Field: Coordinate System

Vertices can be specified in two ways: using “Absolute”/“World” coordinates, or **relative** coordinate specification. Relative coordinates allow flexibility of rapid change to observe changes in building results due to orientation and position. “World” coordinates will facilitate use within a CADD system structure.

**Relative** coordinates make use of both Building and Zone North Axis values as well as Zone Origin values to locate the surface in 3D coordinate space. **World** coordinates do not use these values.

Typically, all zone origin values for “World” coordinates will be (0,0,0) but Building and Zone North Axis values may be used in certain instances (namely the Daylighting Coordinate Location entries).

#### 1.9.11.4 Field: Daylighting Reference Point Coordinate System

Daylighting reference points need to be specified as well. Again, there can be two flavors: **relative** and **world**. Daylighting reference points must fit within the zone boundaries.

**Relative** coordinates make use of both Building and Zone North Axis values as well as Zone Origin values to locate the reference point in 3D coordinate space. **World** coordinates do not use these values.

#### 1.9.11.5 Field: Rectangular Surface Coordinate System

Simple, rectangular surfaces (Wall:Exterior, Wall:Adiabatic, Wall:Underground, Wall:Interzone, Roof, Ceiling:Adiabatic, Ceiling:Interzone, Floor:GroundContact, Floor:Adiabatic, Floor:Interzone) can be specified with their Lower Left Corner as **relative** or **world**.

**Relative** (default) corners are specified relative to the Zone Origin for each surface. **World** corners would specify the absolute/world coordinate for this corner.

### 1.9.12 Surfaces

Surfaces make up the buildings and the elements that shade buildings. There are several methods to inputting surfaces, ranging from simple rectangular surfaces to detailed descriptions that describe each vertex in the order specified in the GlobalGeometryRules object. The simple, rectangular surface objects are described first with the more detailed descriptions following.

### 1.9.13 Walls

Walls are usually vertical (tilt = 90 degrees). These objects are used to describe exterior walls, interior walls (adiabatic), underground walls, and walls adjacent to other zones.

#### 1.9.14 Wall:Exterior

The Wall:Exterior object is used to describe walls that are exposed to the external environment. They receive sun, wind – all the characteristics of the external world.

##### 1.9.14.1 Field: Name

This is a unique name associated with the exterior wall. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

##### 1.9.14.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

##### 1.9.14.3 Field: Zone Name

This is the zone name to which the surface belongs.

##### 1.9.14.4 Field: Azimuth Angle

The Azimuth Angle indicates the direction that the wall faces (outward normal). The angle is specified in degrees where East=90, South=180, West=270, North=0.

##### 1.9.14.5 Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Normally, walls are tilted 90 degrees and that is the default for this field.

##### 1.9.14.6 Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the GlobalGeometryRules object.

##### 1.9.14.7 Field: Starting X Coordinate

This field is the X coordinate (in meters).

##### 1.9.14.8 Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

##### 1.9.14.9 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

##### 1.9.14.10 Field: Length

This field is the length of the wall in meters.

##### 1.9.14.11 Field: Height

This field is the height of the wall in meters.

#### 1.9.15 Wall:Adiabatic

The Wall:Adiabatic object is used to describe interior walls and partitions. Adiabatic walls are used to describe walls next to zones that have the same thermal conditions (thus, no heat transfer).

##### 1.9.15.1 Field: Name

This is a unique name associated with the interior wall. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

#### 1.9.15.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

#### 1.9.15.3 Field: Zone Name

This is the zone name to which the surface belongs.

#### 1.9.15.4 Field: Azimuth Angle

The Azimuth Angle indicates the direction that the wall faces (outward normal). The angle is specified in degrees where East=90, South=180, West=270, North=0.

#### 1.9.15.5 Field: Tilt Angle

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Normally, walls are tilted 90 degrees and that is the default for this field.

#### 1.9.15.6 Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the GlobalGeometryRules object.

#### 1.9.15.7 Field: Starting X Coordinate

This field is the X coordinate (in meters).

#### 1.9.15.8 Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

#### 1.9.15.9 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

#### 1.9.15.10 Field: Length

This field is the length of the wall in meters.

#### 1.9.15.11 Field: Height

This field is the height of the wall in meters.

### 1.9.16 Wall:Underground

The Wall:Underground object is used to describe walls with ground contact. The temperature at the outside of the wall is the temperature in the GroundTemperature:BuildingSurface object.

#### 1.9.16.1 Field: Name

This is a unique name associated with the underground wall. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

#### 1.9.16.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones. Note that if the construction is **Construction:CfactorUndergroundWall** then the GroundFCfactoreMethod will be used for this wall.

#### 1.9.16.3 Field: Zone Name

This is the zone name to which the surface belongs.

#### 1.9.16.4 Field: Azimuth Angle

The Azimuth Angle indicates the direction that the wall faces (outward normal). The angle is specified in degrees where East=90, South=180, West=270, North=0.

#### **1.9.16.5 Field: Tilt Angle**

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Normally, walls are tilted 90 degrees and that is the default for this field.

#### **1.9.16.6 Starting Corner for the surface**

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the GlobalGeometryRules object.

#### **1.9.16.7 Field: Starting X Coordinate**

This field is the X coordinate (in meters).

#### **1.9.16.8 Field: Starting Y Coordinate**

This field is the Y coordinate (in meters).

#### **1.9.16.9 Field: Starting Z Coordinate**

This field is the Z coordinate (in meters).

#### **1.9.16.10 Field: Length**

This field is the length of the wall in meters.

#### **1.9.16.11 Field: Height**

This field is the height of the wall in meters.

### **1.9.17 Wall:Interzone**

The Wall:Interzone object is used to describe walls adjacent to zones that are significantly different conditions than the zone with this wall.

#### **1.9.17.1 Field: Name**

This is a unique name associated with the interzone wall. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

#### **1.9.17.2 Field: Construction Name**

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the "full" construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

#### **1.9.17.3 Field: Zone Name**

This is the zone name to which the surface belongs.

#### **1.9.17.4 Field: Outside Boundary Condition Object**

The Outside Boundary Condition Object field is the name of a wall in an adjacent zone or the name of the adjacent zone. If the adjacent zone option is used, the adjacent wall is automatically generated in the adjacent zone. If the surface name is used, it must be in the adjacent zone.

#### **1.9.17.5 Field: Azimuth Angle**

The Azimuth Angle indicates the direction that the wall faces (outward normal). The angle is specified in degrees where East=90, South=180, West=270, North=0.

#### **1.9.17.6 Field: Tilt Angle**

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Normally, walls are tilted 90 degrees and that is the default for this field.

#### **1.9.17.7 Starting Corner for the surface**

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the GlobalGeometryRules object.

#### **1.9.17.8 Field: Starting X Coordinate**

This field is the X coordinate (in meters).

#### **1.9.17.9 Field: Starting Y Coordinate**

This field is the Y coordinate (in meters).

#### **1.9.17.10 Field: Starting Z Coordinate**

This field is the Z coordinate (in meters).

#### **1.9.17.11 Field: Length**

This field is the length of the wall in meters.

#### **1.9.17.12 Field: Height**

This field is the height of the wall in meters.

### **1.9.18 Roofs/Ceilings**

Roofs and ceilings are, by default, flat (tilt = 0 degrees). These objects are used to describe roofs, interior ceilings (adiabatic) and ceilings adjacent to other zones.

#### **1.9.19 Roof**

The Roof object is used to describe roofs that are exposed to the external environment.

##### **1.9.19.1 Field: Name**

This is a unique name associated with the roof. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

##### **1.9.19.2 Field: Construction Name**

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the "full" construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

##### **1.9.19.3 Field: Zone Name**

This is the zone name to which the surface belongs.

##### **1.9.19.4 Field: Azimuth Angle**

The Azimuth Angle indicates the direction of the outward normal for the roof. The angle is specified in degrees where East=90, South=180, West=270, North=0.

##### **1.9.19.5 Field: Tilt Angle**

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Flat roofs are tilted 0 degrees and that is the default for this field.

##### **1.9.19.6 Starting Corner for the surface**

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the GlobalGeometryRules object.

##### **1.9.19.7 Field: Starting X Coordinate**

This field is the X coordinate (in meters).

##### **1.9.19.8 Field: Starting Y Coordinate**

This field is the Y coordinate (in meters).

##### **1.9.19.9 Field: Starting Z Coordinate**

This field is the Z coordinate (in meters).

#### **1.9.19.10 Field: Length**

This field is the length of the roof in meters.

#### **1.9.19.11 Field: Width**

This field is the width of the roof in meters.

### **1.9.20 Ceiling:Adiabatic**

The Ceiling:Adiabatic object is used to describe interior ceilings that separate zones of like conditions.

#### **1.9.20.1 Field: Name**

This is a unique name associated with the ceiling. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

#### **1.9.20.2 Field: Construction Name**

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

#### **1.9.20.3 Field: Zone Name**

This is the zone name to which the surface belongs.

#### **1.9.20.4 Field: Azimuth Angle**

The Azimuth Angle indicates the direction of the outward normal for the roof. The angle is specified in degrees where East=90, South=180, West=270, North=0.

#### **1.9.20.5 Field: Tilt Angle**

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Flat ceilings are tilted 0 degrees and that is the default for this field.

#### **1.9.20.6 Starting Corner for the surface**

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the GlobalGeometryRules object.

#### **1.9.20.7 Field: Starting X Coordinate**

This field is the X coordinate (in meters).

#### **1.9.20.8 Field: Starting Y Coordinate**

This field is the Y coordinate (in meters).

#### **1.9.20.9 Field: Starting Z Coordinate**

This field is the Z coordinate (in meters).

#### **1.9.20.10 Field: Length**

This field is the length of the ceiling in meters.

#### **1.9.20.11 Field: Width**

This field is the width of the ceiling in meters.

### **1.9.21 Ceiling:Interzone**

The Ceiling:Interzone object is used to describe interior ceilings that separate zones of differing conditions (and expect heat transfer through the ceiling from the adjacent zone).

#### **1.9.21.1 Field: Name**

This is a unique name associated with the interzone ceiling. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

#### **1.9.21.2 Field: Construction Name**

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

#### **1.9.21.3 Field: Zone Name**

This is the zone name to which the surface belongs.

#### **1.9.21.4 Field: Outside Boundary Condition Object**

The Outside Boundary Condition Object field is the name of a floor in an adjacent zone or the name of the adjacent zone. If the adjacent zone option is used, the adjacent floor is automatically generated in the adjacent zone. If the surface name is used, it must be in the adjacent zone.

#### **1.9.21.5 Field: Azimuth Angle**

The Azimuth Angle indicates the direction of the outward normal for the roof. The angle is specified in degrees where East=90, South=180, West=270, North=0.

#### **1.9.21.6 Field: Tilt Angle**

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Flat ceilings are tilted 0 degrees and that is the default for this field.

#### **1.9.21.7 Starting Corner for the surface**

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the GlobalGeometryRules object.

#### **1.9.21.8 Field: Starting X Coordinate**

This field is the X coordinate (in meters).

#### **1.9.21.9 Field: Starting Y Coordinate**

This field is the Y coordinate (in meters).

#### **1.9.21.10 Field: Starting Z Coordinate**

This field is the Z coordinate (in meters).

#### **1.9.21.11 Field: Length**

This field is the length of the ceiling in meters.

#### **1.9.21.12 Field: Width**

This field is the width of the ceiling in meters.

### **1.9.22 Floors**

Floors are, by default, flat (tilt = 180 degrees). These objects are used to describe floors on the ground, interior floors (adiabatic) and floors adjacent to other zones.

#### **1.9.23 Floor:GroundContact**

The Floor:GroundContact object is used to describe floors that have ground contact (usually called slabs). The temperature at the outside of the floor is the temperature in the GroundTemperature:BuildingSurface object.

##### **1.9.23.1 Field: Name**

This is a unique name associated with the floor.

##### **1.9.23.2 Field: Construction Name**

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used.

For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones. Note that if the construction is **Construction:FfactorGroundFloor**, then the `GroundFCfactorMethod` will be used with this floor.

#### **1.9.23.3 Field: Zone Name**

This is the zone name to which the surface belongs.

#### **1.9.23.4 Field: Azimuth Angle**

The Azimuth Angle indicates the direction of the outward normal for the roof. The angle is specified in degrees where East=90, South=180, West=270, North=0.

#### **1.9.23.5 Field: Tilt Angle**

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Flat floors are tilted 180 degrees and that is the default for this field.

#### **1.9.23.6 Starting Corner for the surface**

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the `GlobalGeometryRules` object.

#### **1.9.23.7 Field: Starting X Coordinate**

This field is the X coordinate (in meters).

#### **1.9.23.8 Field: Starting Y Coordinate**

This field is the Y coordinate (in meters).

#### **1.9.23.9 Field: Starting Z Coordinate**

This field is the Z coordinate (in meters).

#### **1.9.23.10 Field: Length**

This field is the length of the floor in meters.

#### **1.9.23.11 Field: Width**

This field is the width of the floor in meters.

### **1.9.24 Floor:Adiabatic**

The `Floor:Adiabatic` object is used to describe interior floors or floors that you wish to model with no heat transfer from the exterior to the floor.

#### **1.9.24.1 Field: Name**

This is a unique name associated with the floor.

#### **1.9.24.2 Field: Construction Name**

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

#### **1.9.24.3 Field: Zone Name**

This is the zone name to which the surface belongs.

#### **1.9.24.4 Field: Azimuth Angle**

The Azimuth Angle indicates the direction of the outward normal for the roof. The angle is specified in degrees where East=90, South=180, West=270, North=0.

#### **1.9.24.5 Field: Tilt Angle**

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Flat floors are tilted 180 degrees and that is the default for this field.

#### **1.9.24.6 Starting Corner for the surface**

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the GlobalGeometryRules object.

#### **1.9.24.7 Field: Starting X Coordinate**

This field is the X coordinate (in meters).

#### **1.9.24.8 Field: Starting Y Coordinate**

This field is the Y coordinate (in meters).

#### **1.9.24.9 Field: Starting Z Coordinate**

This field is the Z coordinate (in meters).

#### **1.9.24.10 Field: Length**

This field is the length of the floor in meters.

#### **1.9.24.11 Field: Width**

This field is the width of the floor in meters.

### **1.9.25 Floor:Interzone**

The Floor:Interzone object is used to describe floors that are adjacent to other zones that have differing conditions and you wish to model the heat transfer through the floor.

#### **1.9.25.1 Field: Name**

This is a unique name associated with the floor.

#### **1.9.25.2 Field: Construction Name**

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the "full" construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

#### **1.9.25.3 Field: Zone Name**

This is the zone name to which the surface belongs.

#### **1.9.25.4 Field: Outside Boundary Condition Object**

The Outside Boundary Condition Object field is the name of a ceiling in an adjacent zone or the name of the adjacent zone. If the adjacent zone option is used, the adjacent ceiling is automatically generated in the adjacent zone. If the surface name is used, it must be in the adjacent zone.

#### **1.9.25.5 Field: Azimuth Angle**

The Azimuth Angle indicates the direction of the outward normal for the roof. The angle is specified in degrees where East=90, South=180, West=270, North=0.

#### **1.9.25.6 Field: Tilt Angle**

The tilt angle is the angle (in degrees) that the wall is tilted from horizontal (or the ground). Flat floors are tilted 180 degrees and that is the default for this field.

#### **1.9.25.7 Starting Corner for the surface**

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. This is specified with (x,y,z) and can be relative to the zone origin or in world coordinates, depending on the value for rectangular surfaces specified in the GlobalGeometryRules object.

#### **1.9.25.8 Field: Starting X Coordinate**

This field is the X coordinate (in meters).

#### **1.9.25.9 Field: Starting Y Coordinate**

This field is the Y coordinate (in meters).

#### 1.9.25.10 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

#### 1.9.25.11 Field: Length

This field is the length of the floor in meters.

#### 1.9.25.12 Field: Width

This field is the width of the floor in meters.

### 1.9.26 Windows/Doors

The following window and door objects can be used to specify simple, rectangular doors and windows. In each case, the lower left corner (locator coordinate) of the window or door is specified **relative** to the surface it is on. Viewing the base surface as a planar surface, base the relative location from the lower left corner of the base surface. Vertex entry description as well as provisions for a few other surface types can be entered with the FenestrationSurface:Detailed object.

#### 1.9.27 Window

The Window object is used to place windows on surfaces that can have windows, including exterior walls, interior walls, interzone walls, roofs, floors that are exposed to outdoor conditions, interzone ceiling/floors. These, of course, can be entered using the simple rectangular objects or the more detailed vertex entry objects.

##### 1.9.27.1 Field: Name

This is a unique name associated with the window.

##### 1.9.27.2 Field: Construction Name

This is the name of the subsurface's construction (ref: objects: Construction, Construction:WindowDataFile, Construction:CompexFenestrationState).

For windows, if Construction Name is not found among the constructions on the input (.idf) file, the Window Data File (ref: Construction:WindowDataFile object) will be searched for that Construction Name (see "Importing Windows from WINDOW"). If that file is not present or if the Construction Name does not match the name of an entry on the file, an error will result. If there is a match, a window construction and its corresponding glass and gas materials will be created from the information read from the file.

##### 1.9.27.3 Field: Building Surface Name

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. For example, a surface in contact with the ground (e.g., Outside Boundary Condition = Ground) cannot contain a window. The window assumes the outward facing angle as well as the tilt angle of the base surface.

##### 1.9.27.4 Field: Shading Control Name

This field, if not blank, is the name of the window shading control (ref: WindowProperty:ShadingControl object) for this subsurface. It is used for Surface Type = Window and GlassDoor. To assign a shade to a window or glass door, see WindowMaterial:Shade. To assign a screen, see WindowMaterial:Screen. To assign a blind, see WindowMaterial:Blind. To assign switchable glazing, such as electrochromic glazing, see WindowProperty:ShadingControl.

##### 1.9.27.5 Field: Frame and Divider Name

This field, if not blank, can be used to specify window frame, divider and reveal-surface data (ref: WindowProperty:FrameAndDivider object). It is used only for exterior GlassDoors and rectangular exterior Windows, i.e., those with OutsideFaceEnvironment = Outdoors.

This field should be blank for triangular windows.

##### 1.9.27.6 Field: Multiplier

This field is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier > 1 can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get if you entered each of the multiple subsurfaces separately.

If Multiplier > 1, you will get

--a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

--an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

#### **1.9.27.7 Starting Corner for the surface**

The rectangular subsurfaces specify the lower left corner of the surface for their starting coordinate. This corner is specified relative to the lower left corner of the base surface by specifying the X and Z values from that corner.

#### **1.9.27.8 Field: Starting X Coordinate**

This field is the X coordinate (in meters).

#### **1.9.27.9 Field: Starting Z Coordinate**

This field is the Z coordinate (in meters).

#### **1.9.27.10 Field: Length**

This field is the length of the window in meters.

#### **1.9.27.11 Field: Height**

This field is the height of the window in meters.

### **1.9.28 Door**

The Door object is used to place opaque doors on surfaces that can have doors, including exterior walls, interior walls, interzone walls, roofs, floors that are exposed to outdoor conditions, interzone ceiling/floors. These, of course, can be entered using the simple rectangular objects or the more detailed vertex entry objects.

#### **1.9.28.1 Field: Name**

This is a unique name associated with the door.

#### **1.9.28.2 Field: Construction Name**

This is the name of the subsurface's construction (ref: Construction object)

#### **1.9.28.3 Field: Building Surface Name**

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. The door assumes the outward facing angle as well as the tilt angle of the base surface.

#### **1.9.28.4 Field: Multiplier**

This field is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier > 1 can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get if you entered each of the multiple subsurfaces separately.

If Multiplier > 1, you will get

--a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

--an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

#### **1.9.28.5 Starting Corner for the surface**

The rectangular subsurfaces specify the lower left corner of the surface for their starting coordinate. This corner is specified relative to the lower left corner of the base surface by specifying the X and Z values from that corner.

#### **1.9.28.6 Field: Starting X Coordinate**

This field is the X coordinate (in meters).

#### **1.9.28.7 Field: Starting Z Coordinate**

This field is the Z coordinate (in meters).

#### **1.9.28.8 Field: Length**

This field is the length of the door in meters.

#### **1.9.28.9 Field: Height**

This field is the height of the door in meters.

### **1.9.29 GlazedDoor**

The GlazedDoor object is used to place doors on surfaces that can have doors, including exterior walls, interior walls, interzone walls, roofs, floors that are exposed to outdoor conditions, interzone ceiling/floors. These, of course, can be entered using the simple rectangular objects or the more detailed vertex entry objects.

#### **1.9.29.1 Field: Name**

This is a unique name associated with the glass door.

#### **1.9.29.2 Field: Construction Name**

This is the name of the subsurface's construction (ref: objects: Construction, Construction:WindowDataFile, Construction:ComplexFenestrationState).

For windows, if Construction Name is not found among the constructions on the input (.idf) file, the Window Data File (ref: Construction:WindowDataFile object) will be searched for that Construction Name (see "Importing Windows from WINDOW"). If that file is not present or if the Construction Name does not match the name of an entry on the file, an error will result. If there is a match, a window construction and its corresponding glass and gas materials will be created from the information read from the file.

#### **1.9.29.3 Field: Building Surface Name**

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. For example, a surface in contact with the ground (Outside Boundary Condition = Ground) cannot contain a window. The door assumes the outward facing angle as well as the tilt angle of the base surface.

#### **1.9.29.4 Field: Shading Control Name**

This field, if not blank, is the name of the window shading control (ref: WindowProperty:ShadingControl object) for this subsurface. It is used for Surface Type = Window and GlassDoor. To assign a shade to a window or glass door, see WindowMaterial:Shade. To assign a screen, see WindowMaterial:Screen. To assign a blind, see WindowMaterial:Blind. To assign switchable glazing, such as electrochromic glazing, see WindowProperty:ShadingControl.

#### **1.9.29.5 Field: Frame and Divider Name**

This field, if not blank, can be used to specify window frame, divider and reveal-surface data (ref: WindowProperty:FrameAndDivider object). It is used only for exterior GlassDoors and rectangular exterior Windows, i.e., those with OutsideFaceEnvironment = Outdoors.

This field should be blank for triangular windows.

#### **1.9.29.6 Field: Multiplier**

This field is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier > 1 can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get if you entered each of the multiple subsurfaces separately.

If Multiplier > 1, you will get

--a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

--an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

#### **1.9.29.7 Starting Corner for the surface**

The rectangular subsurfaces specify the lower left corner of the surface for their starting coordinate. This corner is specified relative to the lower left corner of the base surface by specifying the X and Z values from that corner.

#### **1.9.29.8 Field: Starting X Coordinate**

This field is the X coordinate (in meters).

#### **1.9.29.9 Field: Starting Z Coordinate**

This field is the Z coordinate (in meters).

#### **1.9.29.10 Field: Length**

This field is the length of the door in meters.

#### **1.9.29.11 Field: Height**

This field is the height of the door in meters.

### **1.9.30 Window:Interzone**

The Window:Interzone object is used to place windows on surfaces that can have windows, including interzone walls, interzone ceiling/floors. These, of course, can be entered using the simple rectangular objects or the more detailed vertex entry objects.

#### **1.9.30.1 Field: Name**

This is a unique name associated with the window.

#### **1.9.30.2 Field: Construction Name**

This is the name of the subsurface's construction (ref: objects: Construction, Construction:WindowDataFile, Construction:ComplexFenestrationState).

For windows, if Construction Name is not found among the constructions on the input (.idf) file, the Window Data File (ref: Construction:WindowDataFile object) will be searched for that Construction Name (see "Importing Windows from WINDOW"). If that file is not present or if the Construction Name does not match the name of an entry on the file, an error will result. If there is a match, a window construction and its corresponding glass and gas materials will be created from the information read from the file.

#### **1.9.30.3 Field: Building Surface Name**

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. For example, a surface in contact with the ground (Outside Boundary Condition = Ground) cannot contain a window. The window assumes the outward facing angle as well as the tilt angle of the base surface.

#### **1.9.30.4 Field: Outside Boundary Condition Object**

The Outside Boundary Condition Object field is the name of a window in an adjacent zone or the name of the adjacent zone. If the adjacent zone option is used, the adjacent ceiling is automatically generated in the adjacent zone. If the surface name is used, it must be in the adjacent zone.

#### **1.9.30.5 Field: Multiplier**

This field is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier > 1 can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get

if you entered each of the multiple subsurfaces separately.

If Multiplier > 1, you will get

--a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

--an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

#### **1.9.30.6 Starting Corner for the surface**

The rectangular subsurfaces specify the lower left corner of the surface for their starting coordinate. This corner is specified relative to the lower left corner of the base surface by specifying the X and Z values from that corner.

#### **1.9.30.7 Field: Starting X Coordinate**

This field is the X coordinate (in meters).

#### **1.9.30.8 Field: Starting Z Coordinate**

This field is the Z coordinate (in meters).

#### **1.9.30.9 Field: Length**

This field is the length of the window in meters.

#### **1.9.30.10 Field: Height**

This field is the height of the window in meters.

### **1.9.31 Door:Interzone**

The Door:Interzone object is used to place opaque doors on surfaces that can have doors, including interzone walls, interzone ceiling/floors. These, of course, can be entered using the simple rectangular objects or the more detailed vertex entry objects.

#### **1.9.31.1 Field: Name**

This is a unique name associated with the door.

#### **1.9.31.2 Field: Construction Name**

This is the name of the subsurface's construction (ref: Construction object).

#### **1.9.31.3 Field: Building Surface Name**

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. The door assumes the outward facing angle as well as the tilt angle of the base surface.

#### **1.9.31.4 Field: Outside Boundary Condition Object**

The Outside Boundary Condition Object field is the name of a door in an adjacent zone or the name of the adjacent zone. If the adjacent zone option is used, the adjacent ceiling is automatically generated in the adjacent zone. If the surface name is used, it must be in the adjacent zone.

#### **1.9.31.5 Field: Multiplier**

This field is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier > 1 can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get if you entered each of the multiple subsurfaces separately.

If Multiplier > 1, you will get

--a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window

or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

--an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

#### **1.9.31.6 Starting Corner for the surface**

The rectangular subsurfaces specify the lower left corner of the surface for their starting coordinate. This corner is specified relative to the lower left corner of the base surface by specifying the X and Z values from that corner.

#### **1.9.31.7 Field: Starting X Coordinate**

This field is the X coordinate (in meters).

#### **1.9.31.8 Field: Starting Z Coordinate**

This field is the Z coordinate (in meters).

#### **1.9.31.9 Field: Length**

This field is the length of the door in meters.

#### **1.9.31.10 Field: Height**

This field is the height of the door in meters.

### **1.9.32 GlazedDoor:Interzone**

The GlazedDoor:Interzone object is used to place doors on surfaces that can have doors, including interzone walls, interzone ceiling/floors. These, of course, can be entered using the simple rectangular objects or the more detailed vertex entry objects.

#### **1.9.32.1 Field: Name**

This is a unique name associated with the glass door.

#### **1.9.32.2 Field: Construction Name**

This is the name of the subsurface's construction (ref: objects: Construction, Construction:WindowDataFile, Construction:ComplexFenestrationState).

For windows, if Construction Name is not found among the constructions on the input (.idf) file, the Window Data File (ref: Construction:WindowDataFile object) will be searched for that Construction Name (see "Importing Windows from WINDOW"). If that file is not present or if the Construction Name does not match the name of an entry on the file, an error will result. If there is a match, a window construction and its corresponding glass and gas materials will be created from the information read from the file.

#### **1.9.32.3 Field: Building Surface Name**

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. For example, a surface in contact with the ground (Outside Boundary Condition = Ground) cannot contain a window. The door assumes the outward facing angle as well as the tilt angle of the base surface.

#### **1.9.32.4 Field: Outside Boundary Condition Object**

The Outside Boundary Condition Object field is the name of a glazed (glass) door in an adjacent zone or the name of the adjacent zone. If the adjacent zone option is used, the adjacent ceiling is automatically generated in the adjacent zone. If the surface name is used, it must be in the adjacent zone.

#### **1.9.32.5 Field: Multiplier**

This field is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier > 1 can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get if you entered each of the multiple subsurfaces separately.

If Multiplier > 1, you will get

--a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

--an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

### 1.9.32.6 Starting Corner for the surface

The rectangular subsurfaces specify the lower left corner of the surface for their starting coordinate. This corner is specified relative to the lower left corner of the base surface by specifying the X and Z values from that corner.

### 1.9.32.7 Field: Starting X Coordinate

This field is the X coordinate (in meters).

### 1.9.32.8 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

### 1.9.32.9 Field: Length

This field is the length of the door in meters.

### 1.9.32.10 Field: Height

This field is the height of the door in meters.

Examples of the rectangular surfaces are found in the example files 4ZoneWithShading\_Simple\_1.idf and 4ZoneWithShading\_Simple\_2. Some examples:

### 1.9.33 Surface Vertices

Each of the following surfaces:

- BuildingSurface:Detailed
- Wall:Detailed
- RoofCeiling:Detailed
- Floor:Detailed
- FenestrationSurface:Detailed
- Shading:Site:Detailed
- Shading:Building:Detailed
- Shading:Zone:Detailed

use the same vertex input. The numeric parameters indicated below are taken from the BuildingSurface:Detailed definition; the others may not be exactly the same but are identical in configuration. They are also “extensible” – so, if you want more vertices for these surfaces, you may add to the IDD definition as indicated in the “extensible” comment or, as EnergyPlus is “auto-extensible” just add the number of vertices into your input file.. Note that FenestrationSurface:Detailed is not extensible and is limited to 4 (max) vertices. If you leave the Number of Surface Vertex groups blank or enter **autocalculate**, EnergyPlus looks at the number of groups entered and figures out how many coordinate groups are entered.

**Note that the resolution on the surface vertex input is 1 millimeter (.001 meter). Therefore, using vertices that are very close together (<1 mm) may result in invalid dot product and fatal errors during shading calculations.**

Figure 29. Illustration for Surface Vertices

The figure above will help illustrate Surface Vertex entry. The convention used in "GlobalGeometryRules" dictates the order of the vertices (ref: GlobalGeometryRules). In this example, the conventions used are Starting Vertex Position = UpperLeftCorner and Vertex Entry Direction= CounterClockwise. The surfaces for this single zone are:

4,0,0,H, 0,0,0, A,0,0, A,0,H; !(4 vertices, South Wall)

4,A,0,H,A,0,0,A,B,0,A,B,H; !(4 vertices, East Wall)

**ignore other walls that are not shown in this figure**

4,C,0,J,A,0,H,A,B,H,C,B,J; !(4 vertices, roof)

3,C,0,J,0,0,H,A,0,H; !(3 vertices, gable end)

4,0,0,H, 0,0,0, A,0,0, A,0,H; !(4 vertices, South Wall)

Note that in this example, point 1 of the entry is the Upper Left Corner of the rectangular surfaces and the point of the triangle for the 3 sided surface. The east wall shows the order of vertex entry. For horizontal surfaces, any vertex may be chosen as the starting position, but the Vertex Entry Direction convention must be followed. The surface details report (Output: Surfaces:List, Details;) is very useful for reviewing the accuracy of surface geometry inputs (ref: Surface Output Variables/Reports and Variable Dictionary Reports).

From the detailed vertices, EnergyPlus tries to determine the "height" and "width" of the surface. Obviously, this doesn't work well for >4 sided surfaces; for these, if the calculated height and width are not close to the gross area for the surface, the height and width shown will be the square root of the area (and thus a square).

### 1.9.34 Building Surfaces - Detailed

A building surface is necessary for all calculations. There must be at least one building surface per zone. You can use the detailed descriptions as shown below or the simpler, rectangular surface descriptions shown earlier.

### 1.9.35 Wall:Detailed

The Wall:Detailed object is used to describe walls.

#### 1.9.35.1 Field: Name

This is a unique name associated with each building surface. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

#### 1.9.35.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

#### 1.9.35.3 Field: Zone Name

This is the zone name to which the surface belongs.

#### 1.9.35.4 Field: Outside Boundary Condition

This value can be one of several things depending on the actual kind of surface.

- 1) **Surface** – if this surface is an internal surface, then this is the choice. The value will either be a surface in the base zone or a surface in another zone. The heat balance between two zones can be accurately simulated by specifying a surface in an adjacent zone. EnergyPlus will simulate a group of zones simultaneously and will include the heat transfer between zones. However, as this increases the complexity of the calculations, it is not necessary to specify the other zone unless the two zones will have a significant temperature difference. If the two zones will not be very different (temperature wise), then the surface should use itself as the outside environment or specify this field as **Adiabatic**. The surface name on the “outside” of this surface (adjacent to) is placed in the next field.
- 2) **Adiabatic** – an internal surface in the same Zone. This surface will not transfer heat out of the zone, but will still store heat in thermal mass. Only the inside face of the surface will exchange heat with the zone (i.e. two adiabatic surfaces are required to model internal partitions where both sides of the surface are exchanging heat with the zone). The Outside Boundary Condition Object can be left blank.
- 3) **Zone** – this is similar to Surface but EnergyPlus will automatically create the required surface in the adjacent zone when this is entered for the surface. If there are windows or doors on the surface, EnergyPlus automatically creates appropriate sub-surfaces as well.
- 4) **Outdoors** – if this surface is exposed to outside temperature conditions, then this is the choice. See Sun Exposure and Wind Exposure below for further specifications on this kind of surface.
- 5) **Ground** – if this surface is exposed to the ground, then this is the usual choice. The temperature on the outside of this surface will be the Site:GroundTemperature:Surface value for the month. For more information on ground contact surfaces, reference the Auxiliary Programs document section on “Ground Heat Transfer in EnergyPlus”.
- 6) **GroundFCfactorMethod** – if this surface is exposed to the ground and using the **Construction:CfactorUndergroundWall**, then this is the choice. The temperature on the outside of this surface will be the Site:GroundTemperature:FcfactorMethod value for the month.
- 7) **OtherSideCoefficients** – if this surface has a custom, user specified temperature or other parameters (See SurfaceProperty:OtherSideCoefficients specification), then this is the choice. The outside boundary condition will be the name of the SurfaceProperty:OtherSideCoefficients specification.
- 8) **OtherSideConditionsModel** – if this surface has a specially-modeled multi-skin component, such as a transpired collector or vented photovoltaic panel, attached to the outside (See SurfaceProperty:OtherSideConditionsModel specification), then this the choice. The outside face environment will be the name of the SurfaceProperty:OtherSideConditionsModels specification.
- 9) **GroundSlabPreprocessorAverage** – uses the average results from the Slab preprocessor calculations.
- 10) **GroundSlabPreprocessorCore** – uses the core results from the Slab preprocessor calculations.
- 11) **GroundSlabPreprocessorPerimeter** – uses the perimeter results from the Slab preprocessor calculations.
- 12) **GroundBasementPreprocessorAverageWall** – uses the average wall results from the Basement preprocessor calculations.
- 13) **GroundBasementPreprocessorAverageFloor** – uses the average floor results from the Basement preprocessor calculations.
- 14) **GroundBasementPreprocessorUpperWall** – uses the upper wall results from the Basement preprocessor calculations.
- 15) **GroundBasementPreprocessorLowerWall** – uses the lower wall results from the Basement preprocessor calculations.

#### 1.9.35.5 Field: Outside Boundary Condition Object

If neither Surface, OtherSideCoefficients, or OtherSideConditionsModel are specified for the Outside Boundary Condition (previous field), then this field should be left blank.

As stated above, if the Outside Boundary Condition is "Surface", then this field's value must be the surface name whose inside face temperature will be forced on the outside face of the base surface. This permits heat exchange between adjacent zones (interzone heat transfer) when multiple zones are simulated, but can also be used to simulate middle zone behavior without modeling the adjacent zones. This is done by specifying a surface within the zone. For example, a middle floor zone can be modeled by making the floor the Outside Boundary Condition Object for the ceiling, and the ceiling the Outside Boundary Condition Object for the floor.

If the Outside Boundary Condition is Zone, then this field should contain the zone name of the adjacent zone for the surface.

Note: Zones with interzone heat transfer are not adiabatic and the internal surfaces contribute to gains or losses. Adiabatic surfaces are modeled by specifying the base surface itself in this field. Also, for interzone heat transfer, both surfaces must be represented – for example, if you want interzone heat transfer to an attic space, the ceiling in the lower zone must have a surface object with the outside face environment as the floor in the attic and, likewise, there must be a floor surface object in the attic that references the ceiling surface name in the lower zone.

Equally, if the Outside Boundary Condition is "OtherSideCoefficients", then this field's value must be the SurfaceProperty:OtherSideCoefficients name. Or if the Outside Boundary Condition is "OtherSideConditionsModel" then this field's value must be the SurfaceProperty:OtherSideConditionsModel name.

#### 1.9.35.6 Field: Sun Exposure

If the surface is exposed to the sun, then "SunExposed" should be entered in this field. Otherwise, "NoSun" should be entered.

Note, a cantilevered floor could have "Outdoors" but "NoSun" exposure.

#### 1.9.35.7 Field: Wind Exposure

If the surface is exposed to the Wind, then "WindExposed" should be entered in this field. Otherwise, "NoWind" should be entered.

Note: When a surface is specified with "NoWind", this has several implications. Within the heat balance code, this surface will default to using the simple ASHRAE exterior convection coefficient correlation with a zero wind speed. In addition, since the ASHRAE simple method does not have a separate value for equivalent long wavelength radiation to the sky and ground, using "NoWind" also eliminates long wavelength radiant exchange from the exterior of the surface to both the sky and the ground. Thus, only simple convection takes place at the exterior face of a surface specified with "NoWind".

#### 1.9.35.8 Field: View Factor to Ground

The fraction of the ground plane (assumed horizontal) that is visible from a heat-transfer surface. It is used to calculate the diffuse solar radiation from the ground that is incident on the surface.

For example, if there are no obstructions, a vertical surface sees half of the ground plane and so View Factor to Ground = 0.5. A horizontal downward-facing surface sees the entire ground plane, so View Factor to Ground = 1.0. A horizontal upward-facing surface (horizontal roof) does not see the ground at all, so View Factor to Ground = 0.0.

Unused if reflections option in Solar Distribution field in Building object input unless a DaylightingDevice:Shelf or DaylightingDevice:Tubular has been specified.

If you do not use the reflections option in the Solar Distribution field in your Building object input, you are responsible for entering the View Factor to Ground for each heat-transfer surface. Typical values for a surface that is not shadowed are obtained by the simple equation:

$$\text{View Factor to Ground} = (1 - \cos(\text{SurfTilt})) / 2$$

For example, this gives 0.5 for a wall of tilt 90°. If the tilt of the wall changes, then the View Factor to Ground must also change.

If you enter **autocalculate** in this field, EnergyPlus will automatically calculate the view factor to ground based on the tilt of the surface.

If **you do use the reflections option in the Solar Distribution field** in your Building object input, you **do not** have to enter View Factor to Ground values. In this case the program will automatically calculate the value to use for each exterior surface taking into account solar shadowing (including shadowing of the ground by the building) and reflections from obstructions (ref: Building, Field: Solar Distribution).

However, if you do use the reflections option AND you are modeling a DaylightingDevice:Shelf or DaylightingDevice:Tubular, then you still need to enter some values of View Factor to Ground. For DaylightingDevice:Shelf you need to enter View Factor to Ground for the window associated with the shelf. And for DaylightingDevice:Tubular you need to enter the View Factor to Ground for the FenestrationSurface:Detailed corresponding to the dome of the tubular device.

Note 1: The corresponding view factor to the sky for diffuse solar radiation is not a user input; it is calculated within EnergyPlus based on surface orientation, sky solar radiance distribution, and shadowing surfaces.

Note 2: The view factors to the sky and ground for thermal infrared (long-wave) radiation are not user inputs; they are calculated within EnergyPlus based on surface tilt and shadowing surfaces. Shadowing surfaces are considered to have the same emissivity and temperature as the ground, so they are lumped together with the ground in calculating the ground IR view factor.

#### 1.9.35.9 Field: Number of Vertices

This field specifies the number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on "Surface Vertices" above.

## 1.9.36 RoofCeiling:Detailed

The RoofCeiling:Detailed object is used to describe walls.

### 1.9.36.1 Field: Name

This is a unique name associated with each building surface. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

### 1.9.36.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

### 1.9.36.3 Field: Zone Name

This is the zone name to which the surface belongs.

### 1.9.36.4 Field: Outside Boundary Condition

This value can be one of several things depending on the actual kind of surface.

- 1) **Surface** – if this surface is an internal surface, then this is the choice. The value will either be a surface in the base zone or a surface in another zone. The heat balance between two zones can be accurately simulated by specifying a surface in an adjacent zone. EnergyPlus will simulate a group of zones simultaneously and will include the heat transfer between zones. However, as this increases the complexity of the calculations, it is not necessary to specify the other zone unless the two zones will have a significant temperature difference. If the two zones will not be very different (temperature wise), then the surface should use itself as the outside environment or specify this field as **Adiabatic**. The surface name on the “outside” of this surface (adjacent to) is placed in the next field.
- 2) **Adiabatic** – an internal surface in the same Zone. This surface will not transfer heat out of the zone, but will still store heat in thermal mass. Only the inside face of the surface will exchange heat with the zone (i.e. two adiabatic surfaces are required to model internal partitions where both sides of the surface are exchanging heat with the zone). The Outside Boundary Condition Object can be left blank.
- 3) **Zone** – this is similar to Surface but EnergyPlus will automatically create the required surface in the adjacent zone when this is entered for the surface. If there are windows or doors on the surface, EnergyPlus automatically creates appropriate sub-surfaces as well.
- 4) **Outdoors** – if this surface is exposed to outside temperature conditions, then this is the choice. See Sun Exposure and Wind Exposure below for further specifications on this kind of surface.
- 5) **Ground** – if this surface is exposed to the ground, then this is the choice. The temperature on the outside of this surface will be the Ground Temperature.
- 6) **OtherSideCoefficients** – if this surface has a custom, user specified temperature or other parameters (See SurfaceProperty:OtherSideCoefficients specification), then this is the choice. The outside boundary condition will be the name of the SurfaceProperty:OtherSideCoefficients specification.
- 7) **OtherSideConditionsModel** – if this surface has a specially-modeled multi-skin component, such as a transpired collector or vented photovoltaic panel, attached to the outside (See SurfaceProperty:OtherSideConditionsModel specification), then this the choice. The outside face environment will be the name of the SurfaceProperty:OtherSideConditionsModels specification.
- 8) **GroundSlabPreprocessorAverage** – uses the average results from the Slab preprocessor calculations.
- 9) **GroundSlabPreprocessorCore** – uses the core results from the Slab preprocessor calculations.
- 10) **GroundSlabPreprocessorPerimeter** – uses the perimeter results from the Slab preprocessor calculations.
- 11) **GroundBasementPreprocessorAverageWall** – uses the average wall results from the Basement preprocessor calculations.
- 12) **GroundBasementPreprocessorAverageFloor** – uses the average floor results from the Basement preprocessor calculations.
- 13) **GroundBasementPreprocessorUpperWall** – uses the upper wall results from the Basement preprocessor calculations.
- 14) **GroundBasementPreprocessorLowerWall** – uses the lower wall results from the Basement preprocessor calculations.

### 1.9.36.5 Field: Outside Boundary Condition Object

If neither Surface, OtherSideCoefficients, or OtherSideConditionsModel are specified for the Outside Boundary Condition (previous field), then this field should be left blank.

As stated above, if the Outside Boundary Condition is “Surface”, then this field’s value must be the surface name whose inside face temperature will be forced on the outside face of the base surface. This permits heat exchange between adjacent zones (interzone heat transfer) when multiple zones are simulated, but can

also be used to simulate middle zone behavior without modeling the adjacent zones. This is done by specifying a surface within the zone. For example, a middle floor zone can be modeled by making the floor the Outside Boundary Condition Object for the ceiling, and the ceiling the Outside Boundary Condition Object for the floor.

If the Outside Boundary Condition is Zone, then this field should contain the zone name of the adjacent zone for the surface.

Note: Zones with interzone heat transfer are not adiabatic and the internal surfaces contribute to gains or losses. Adiabatic surfaces are modeled by specifying the base surface itself in this field. Also, for interzone heat transfer, both surfaces must be represented – for example, if you want interzone heat transfer to an attic space, the ceiling in the lower zone must have a surface object with the outside face environment as the floor in the attic and, likewise, there must be a floor surface object in the attic that references the ceiling surface name in the lower zone.

Equally, if the Outside Boundary Condition is “OtherSideCoefficients”, then this field’s value must be the SurfaceProperty:OtherSideCoefficients name. Or if the Outside Boundary Condition is “OtherSideConditionsModel” then this field’s value must be the SurfaceProperty:OtherSideConditionsModel name.

#### 1.9.36.6 Field: Sun Exposure

If the surface is exposed to the sun, then “SunExposed” should be entered in this field. Otherwise, “NoSun” should be entered.

Note, a cantilevered floor could have “Outdoors” but “NoSun” exposure.

#### 1.9.36.7 Field: Wind Exposure

If the surface is exposed to the Wind, then “WindExposed” should be entered in this field. Otherwise, “NoWind” should be entered.

Note: When a surface is specified with “NoWind”, this has several implications. Within the heat balance code, this surface will default to using the simple ASHRAE exterior convection coefficient correlation with a zero wind speed. In addition, since the ASHRAE simple method does not have a separate value for equivalent long wavelength radiation to the sky and ground, using “NoWind” also eliminates long wavelength radiant exchange from the exterior of the surface to both the sky and the ground. Thus, only simple convection takes place at the exterior face of a surface specified with “NoWind”.

#### 1.9.36.8 Field: View Factor to Ground

The fraction of the ground plane (assumed horizontal) that is visible from a heat-transfer surface. It is used to calculate the diffuse solar radiation from the ground that is incident on the surface.

For example, if there are no obstructions, a vertical surface sees half of the ground plane and so View Factor to Ground = 0.5. A horizontal downward-facing surface sees the entire ground plane, so View Factor to Ground = 1.0. A horizontal upward-facing surface (horizontal roof) does not see the ground at all, so View Factor to Ground = 0.0.

Unused if reflections option in Solar Distribution field in Building object input unless a DaylightingDevice:Shelf or DaylightingDevice:Tubular has been specified.

If you do not use the reflections option in the Solar Distribution field in your Building object input, you are responsible for entering the View Factor to Ground for each heat-transfer surface. Typical values for a surface that is not shadowed are obtained by the simple equation:

$$\text{View Factor to Ground} = (1 - \cos(\text{SurfTilt})) / 2$$

For example, this gives 0.5 for a wall of tilt 90°. If the tilt of the wall changes, then the View Factor to Ground must also change.

If you enter **autocalculate** in this field, EnergyPlus will automatically calculate the view factor to ground based on the tilt of the surface.

If **you do use the reflections option in the Solar Distribution field** in your Building object input, you do **not** have to enter View Factor to Ground values. In this case the program will automatically calculate the value to use for each exterior surface taking into account solar shadowing (including shadowing of the ground by the building) and reflections from obstructions (ref: Building, Field: Solar Distribution).

However, if you do use the reflections option AND you are modeling a DaylightingDevice:Shelf or DaylightingDevice:Tubular, then you still need to enter some values of View Factor to Ground. For DaylightingDevice:Shelf you need to enter View Factor to Ground for the window associated with the shelf. And for DaylightingDevice:Tubular you need to enter the View Factor to Ground for the FenestrationSurface:Detailed corresponding to the dome of the tubular device.

Note 1: The corresponding view factor to the sky for diffuse solar radiation is not a user input; it is calculated within EnergyPlus based on surface orientation, sky solar radiance distribution, and shadowing surfaces.

Note 2: The view factors to the sky and ground for thermal infrared (long-wave) radiation are not user inputs; they are calculated within EnergyPlus based on surface tilt and shadowing surfaces. Shadowing surfaces are considered to have the same emissivity and temperature as the ground, so they are lumped together with the ground in calculating the ground IR view factor.

#### 1.9.36.9 Field: Number of Vertices

This field specifies the number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on “Surface Vertices” above.

### 1.9.37 Floor:Detailed

The Floor:Detailed object is used to describe walls.

#### 1.9.37.1 Field: Name

This is a unique name associated with each building surface. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

#### 1.9.37.2 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

#### 1.9.37.3 Field: Zone Name

This is the zone name to which the surface belongs.

#### 1.9.37.4 Field: Outside Boundary Condition

This value can be one of several things depending on the actual kind of surface.

- 1) **Surface** – if this surface is an internal surface, then this is the choice. The value will either be a surface in the base zone or a surface in another zone. The heat balance between two zones can be accurately simulated by specifying a surface in an adjacent zone. EnergyPlus will simulate a group of zones simultaneously and will include the heat transfer between zones. However, as this increases the complexity of the calculations, it is not necessary to specify the other zone unless the two zones will have a significant temperature difference. If the two zones will not be very different (temperature wise), then the surface should use itself as the outside environment or specify this field as **Adiabatic**. The surface name on the “outside” of this surface (adjacent to) is placed in the next field.
- 2) **Adiabatic** – an internal surface in the same Zone. This surface will not transfer heat out of the zone, but will still store heat in thermal mass. Only the inside face of the surface will exchange heat with the zone (i.e. two adiabatic surfaces are required to model internal partitions where both sides of the surface are exchanging heat with the zone). The Outside Boundary Condition Object can be left blank.
- 3) **Zone** – this is similar to Surface but EnergyPlus will automatically create the required surface in the adjacent zone when this is entered for the surface. If there are windows or doors on the surface, EnergyPlus automatically creates appropriate sub-surfaces as well.
- 4) **Outdoors** – if this surface is exposed to outside temperature conditions, then this is the choice. See Sun Exposure and Wind Exposure below for further specifications on this kind of surface.
- 5) **Ground** – if this surface is exposed to the ground, then this is the usual choice. The temperature on the outside of this surface will be the Site:GroundTemperature:Surface value for the month. For more information on ground contact surfaces, reference the Auxiliary Programs document section on “Ground Heat Transfer in EnergyPlus”.
- 6) **GroundFCfactorMethod** – if this surface is exposed to the ground and using the **Construction:FfactorGroundFloor**, then this is the choice. The temperature on the outside of this surface will be the Site:GroundTemperature:FfactorMethod value for the month.
- 7) **OtherSideCoefficients** – if this surface has a custom, user specified temperature or other parameters (See SurfaceProperty:OtherSideCoefficients specification), then this is the choice. The outside boundary condition will be the name of the SurfaceProperty:OtherSideCoefficients specification.
- 8) **OtherSideConditionsModel** – if this surface has a specially-modeled multi-skin component, such as a transpired collector or vented photovoltaic panel, attached to the outside (See SurfaceProperty:OtherSideConditionsModel specification), then this the choice. The outside face environment will be the name of the SurfaceProperty:OtherSideConditionsModels specification.
- 9) **GroundSlabPreprocessorAverage** – uses the average results from the Slab preprocessor calculations.
- 10) **GroundSlabPreprocessorCore** – uses the core results from the Slab preprocessor calculations.
- 11) **GroundSlabPreprocessorPerimeter** – uses the perimeter results from the Slab preprocessor calculations.
- 12) **GroundBasementPreprocessorAverageWall** – uses the average wall results from the Basement preprocessor calculations.
- 13) **GroundBasementPreprocessorAverageFloor** – uses the average floor results from the Basement preprocessor calculations.
- 14) **GroundBasementPreprocessorUpperWall** – uses the upper wall results from the Basement preprocessor calculations.
- 15) **GroundBasementPreprocessorLowerWall** – uses the lower wall results from the Basement preprocessor calculations.

#### 1.9.37.5 Field: Outside Boundary Condition Object

If neither Surface, OtherSideCoefficients, or OtherSideConditionsModel are specified for the Outside Boundary Condition (previous field), then this field should be left blank.

As stated above, if the Outside Boundary Condition is "Surface", then this field's value must be the surface name whose inside face temperature will be forced on the outside face of the base surface. This permits heat exchange between adjacent zones (interzone heat transfer) when multiple zones are simulated, but can also be used to simulate middle zone behavior without modeling the adjacent zones. This is done by specifying a surface within the zone. For example, a middle floor zone can be modeled by making the floor the Outside Boundary Condition Object for the ceiling, and the ceiling the Outside Boundary Condition Object for the floor.

If the Outside Boundary Condition is Zone, then this field should contain the zone name of the adjacent zone for the surface.

Note: Zones with interzone heat transfer are not adiabatic and the internal surfaces contribute to gains or losses. Adiabatic surfaces are modeled by specifying the base surface itself in this field. Also, for interzone heat transfer, both surfaces must be represented – for example, if you want interzone heat transfer to an attic space, the ceiling in the lower zone must have a surface object with the outside face environment as the floor in the attic and, likewise, there must be a floor surface object in the attic that references the ceiling surface name in the lower zone.

Equally, if the Outside Boundary Condition is "OtherSideCoefficients", then this field's value must be the SurfaceProperty:OtherSideCoefficients name. Or if the Outside Boundary Condition is "OtherSideConditionsModel" then this field's value must be the SurfaceProperty:OtherSideConditionsModel name.

#### 1.9.37.6 Field: Sun Exposure

If the surface is exposed to the sun, then "SunExposed" should be entered in this field. Otherwise, "NoSun" should be entered.

Note, a cantilevered floor could have "Outdoors" but "NoSun" exposure.

#### 1.9.37.7 Field: Wind Exposure

If the surface is exposed to the Wind, then "WindExposed" should be entered in this field. Otherwise, "NoWind" should be entered.

Note: When a surface is specified with "NoWind", this has several implications. Within the heat balance code, this surface will default to using the simple ASHRAE exterior convection coefficient correlation with a zero wind speed. In addition, since the ASHRAE simple method does not have a separate value for equivalent long wavelength radiation to the sky and ground, using "NoWind" also eliminates long wavelength radiant exchange from the exterior of the surface to both the sky and the ground. Thus, only simple convection takes place at the exterior face of a surface specified with "NoWind".

#### 1.9.37.8 Field: View Factor to Ground

The fraction of the ground plane (assumed horizontal) that is visible from a heat-transfer surface. It is used to calculate the diffuse solar radiation from the ground that is incident on the surface.

For example, if there are no obstructions, a vertical surface sees half of the ground plane and so View Factor to Ground = 0.5. A horizontal downward-facing surface sees the entire ground plane, so View Factor to Ground = 1.0. A horizontal upward-facing surface (horizontal roof) does not see the ground at all, so View Factor to Ground = 0.0.

Unused if reflections option in Solar Distribution field in Building object input unless a DaylightingDevice:Shelf or DaylightingDevice:Tubular has been specified.

If you do not use the reflections option in the Solar Distribution field in your Building object input, you are responsible for entering the View Factor to Ground for each heat-transfer surface. Typical values for a surface that is not shadowed are obtained by the simple equation:

$$\text{View Factor to Ground} = (1 - \cos(\text{SurfTilt})) / 2$$

For example, this gives 0.5 for a wall of tilt 90°. If the tilt of the wall changes, then the View Factor to Ground must also change.

If you enter **autocalculate** in this field, EnergyPlus will automatically calculate the view factor to ground based on the tilt of the surface.

If **you do use the reflections option in the Solar Distribution field** in your Building object input, you **do not** have to enter View Factor to Ground values. In this case the program will automatically calculate the value to use for each exterior surface taking into account solar shadowing (including shadowing of the ground by the building) and reflections from obstructions (ref: Building, Field: Solar Distribution).

However, if you do use the reflections option AND you are modeling a DaylightingDevice:Shelf or DaylightingDevice:Tubular, then you still need to enter some values of View Factor to Ground. For DaylightingDevice:Shelf you need to enter View Factor to Ground for the window associated with the shelf. And for DaylightingDevice:Tubular you need to enter the View Factor to Ground for the FenestrationSurface:Detailed corresponding to the dome of the tubular device.

Note 1: The corresponding view factor to the sky for diffuse solar radiation is not a user input; it is calculated within EnergyPlus based on surface orientation, sky solar radiance distribution, and shadowing surfaces.

Note 2: The view factors to the sky and ground for thermal infrared (long-wave) radiation are not user inputs; they are calculated within EnergyPlus based on surface tilt and shadowing surfaces. Shadowing surfaces are considered to have the same emissivity and temperature as the ground, so they are lumped together with the ground in calculating the ground IR view factor.

#### 1.9.37.9 Field: Number of Vertices

This field specifies the number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on "Surface Vertices" above.

Some examples of using these objects:

```
Floor:Detailed,
  Floor_NorthZone_1stFloor, !- Name
  FLOOR-SLAB-ASSEMBLY,     !- Construction Name
  NorthZone_1stFloor,      !- Zone Name
  Ground,                   !- Outside Boundary Condition
  ,                          !- Outside Boundary Condition Object
  NoSun,                    !- Sun Exposure
  NoWind,                   !- Wind Exposure
  0.0,                       !- View Factor to Ground
  4,                         !- Number of Vertices
  0, 11, 0,                 !- X,Y,Z 1 {m}
  25, 11, 0,                !- X,Y,Z 2 {m}
  25, 5.5, 0,               !- X,Y,Z 3 {m}
  0, 5.5, 0;                !- X,Y,Z 4 {m}

  0, 5.5, 0,                      !- X,Y,Z 3 {m}
  0, 5.5, 3.7;                   !- X,Y,Z 4 {m}
```

### 1.9.38 BuildingSurface:Detailed

The BuildingSurface:Detailed object can more generally describe each of the surfaces.

#### 1.9.38.1 Field: Name

This is a unique name associated with each building surface. It is used in several other places as a reference (e.g. as the base surface name for a Window or Door).

#### 1.9.38.2 Field: Surface Type

Used primarily for convenience, the surface type can be one of the choices illustrated above – Wall, Floor, Ceiling, Roof. Azimuth (facing) and Tilt are determined from the vertex coordinates. Note that “normal” floors will be tilted 180° whereas flat roofs/ceilings will be tilted 0°. EnergyPlus uses this field’s designation, along with the calculated tilt of the surface, to issue warning messages when tilts are “out of range”. Calculations in EnergyPlus use the actual calculated tilt values for the actual heat balance calculations. Note, however, that a floor tilted 0° is really facing “into” the zone and is not what you will desire for the calculations even though the coordinate may appear correct in the viewed DXF display.

“Normal” tilt for walls is 90° -- here you may use the calculated Azimuth to make sure your walls are facing away from the zone’s interior.

#### 1.9.38.3 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface. Regardless of location in the building, the “full” construction (all layers) is used. For example, for an interior wall separating two zones, zone x would have the outside layer (e.g. drywall) as the material that shows in zone y and then the layers to the inside layer – the material that shows in zone x. For symmetric constructions, the same construction can be used in the surfaces described in both zones.

#### 1.9.38.4 Field: Zone Name

This is the zone name to which the surface belongs.

### 1.9.38.5 Field: Outside Boundary Condition

This value can be one of several things depending on the actual kind of surface.

- 1) **Surface** – if this surface is an internal surface, then this is the choice. The value will either be a surface in the base zone or a surface in another zone. The heat balance between two zones can be accurately simulated by specifying a surface in an adjacent zone. EnergyPlus will simulate a group of zones simultaneously and will include the heat transfer between zones. However, as this increases the complexity of the calculations, it is not necessary to specify the other zone unless the two zones will have a significant temperature difference. If the two zones will not be very different (temperature wise), then the surface should use itself as the outside environment or specify this field as **Adiabatic**. In either case, the surface name on the “outside” of this surface (adjacent to) is placed in the next field.
- 2) **Adiabatic** – an internal surface in the same Zone. This surface will not transfer heat out of the zone, but will still store heat in thermal mass. Only the inside face of the surface will exchange heat with the zone (i.e. two adiabatic surfaces are required to model internal partitions where both sides of the surface are exchanging heat with the zone). The Outside Boundary Condition Object can be left blank.
- 3) **Zone** – this is similar to Surface but EnergyPlus will automatically create the required surface in the adjacent zone when this is entered for the surface. If there are windows or doors on the surface, EnergyPlus automatically creates appropriate sub-surfaces as well.
- 4) **Outdoors** – if this surface is exposed to outside temperature conditions, then this is the choice. See Sun Exposure and Wind Exposure below for further specifications on this kind of surface.
- 5) **Ground** – if this surface is exposed to the ground, then this is the usual choice. The temperature on the outside of this surface will be the Site:GroundTemperature:Surface value for the month. For more information on ground contact surfaces, reference the Auxiliary Programs document section on “Ground Heat Transfer in EnergyPlus”.
- 6) **GroundFCfactorMethod** – if this surface is exposed to the ground and using the **Construction:CfactorUndergroundWall** or **Construction:FfactorGroundFloor** (depending on surface type), then this is the choice. The temperature on the outside of this surface will be the Site:GroundTemperature:FfactorMethod value for the month.
- 7) **OtherSideCoefficients** – if this surface has a custom, user specified temperature or other parameters (See SurfaceProperty:OtherSideCoefficients specification), then this is the choice. The outside boundary condition will be the name of the SurfaceProperty:OtherSideCoefficients specification.
- 8) **OtherSideConditionsModel** – if this surface has a specially-modeled multi-skin component, such as a transpired collector or vented photovoltaic panel, attached to the outside (See SurfaceProperty:OtherSideConditionsModel specification), then this the choice. The outside face environment will be the name of the SurfaceProperty:OtherSideConditionsModels specification.
- 9) **GroundSlabPreprocessorAverage** – uses the average results from the Slab preprocessor calculations.
- 10) **GroundSlabPreprocessorCore** – uses the core results from the Slab preprocessor calculations.
- 11) **GroundSlabPreprocessorPerimeter** – uses the perimeter results from the Slab preprocessor calculations.
- 12) **GroundBasementPreprocessorAverageWall** – uses the average wall results from the Basement preprocessor calculations.
- 13) **GroundBasementPreprocessorAverageFloor** – uses the average floor results from the Basement preprocessor calculations.
- 14) **GroundBasementPreprocessorUpperWall** – uses the upper wall results from the Basement preprocessor calculations.
- 15) **GroundBasementPreprocessorLowerWall** – uses the lower wall results from the Basement preprocessor calculations.

### 1.9.38.6 Field: Outside Boundary Condition Object

If neither Surface, OtherSideCoefficients, or OtherSideConditionsModel are specified for the Outside Boundary Condition (previous field), then this field should be left blank.

As stated above, if the Outside Boundary Condition is “Surface”, then this field’s value must be the surface name whose inside face temperature will be forced on the outside face of the base surface. This permits heat exchange between adjacent zones (interzone heat transfer) when multiple zones are simulated, but can also be used to simulate middle zone behavior without modeling the adjacent zones. This is done by specifying a surface within the zone. For example, a middle floor zone can be modeled by making the floor the Outside Boundary Condition Object for the ceiling, and the ceiling the Outside Boundary Condition Object for the floor.

If the Outside Boundary Condition is Zone, then this field should contain the zone name of the adjacent zone for the surface.

Note: Zones with interzone heat transfer are not adiabatic and the internal surfaces contribute to gains or losses. Adiabatic surfaces are modeled by specifying the base surface itself in this field. Also, for interzone heat transfer, both surfaces must be represented – for example, if you want interzone heat transfer to an attic space, the ceiling in the lower zone must have a surface object with the outside face environment as the floor in the attic and, likewise, there must be a floor surface object in the attic that references the ceiling surface name in the lower zone.

Equally, if the Outside Boundary Condition is “OtherSideCoefficients”, then this field’s value must be the SurfaceProperty:OtherSideCoefficients name. Or if the Outside Boundary Condition is “OtherSideConditionsModel” then this field’s value must be the SurfaceProperty:OtherSideConditionsModel name.

### 1.9.38.7 Field: Sun Exposure

If the surface is exposed to the sun, then "SunExposed" should be entered in this field. Otherwise, "NoSun" should be entered.

Note, a cantilevered floor could have "Outdoors" but "NoSun" exposure.

### 1.9.38.8 Field: Wind Exposure

If the surface is exposed to the Wind, then "WindExposed" should be entered in this field. Otherwise, "NoWind" should be entered.

Note: When a surface is specified with "NoWind", this has several implications. Within the heat balance code, this surface will default to using the simple ASHRAE exterior convection coefficient correlation with a zero wind speed. In addition, since the ASHRAE simple method does not have a separate value for equivalent long wavelength radiation to the sky and ground, using "NoWind" also eliminates long wavelength radiant exchange from the exterior of the surface to both the sky and the ground. Thus, only simple convection takes place at the exterior face of a surface specified with "NoWind".

### 1.9.38.9 Field: View Factor to Ground

The fraction of the ground plane (assumed horizontal) that is visible from a heat-transfer surface. It is used to calculate the diffuse solar radiation from the ground that is incident on the surface.

For example, if there are no obstructions, a vertical surface sees half of the ground plane and so View Factor to Ground = 0.5. A horizontal downward-facing surface sees the entire ground plane, so View Factor to Ground = 1.0. A horizontal upward-facing surface (horizontal roof) does not see the ground at all, so View Factor to Ground = 0.0.

Unused if reflections option in Solar Distribution field in Building object input unless a DaylightingDevice:Shelf or DaylightingDevice:Tubular has been specified.

If you do not use the reflections option in the Solar Distribution field in your Building object input, you are responsible for entering the View Factor to Ground for each heat-transfer surface. Typical values for a surface that is not shadowed are obtained by the simple equation:

$$\text{View Factor to Ground} = (1 - \cos(\text{SurfTilt})) / 2$$

For example, this gives 0.5 for a wall of tilt 90°. If the tilt of the wall changes, then the View Factor to Ground must also change.

If you enter **autocalculate** in this field, EnergyPlus will automatically calculate the view factor to ground based on the tilt of the surface.

If **you do use the reflections option in the Solar Distribution field** in your Building object input, you **do not** have to enter View Factor to Ground values. In this case the program will automatically calculate the value to use for each exterior surface taking into account solar shadowing (including shadowing of the ground by the building) and reflections from obstructions (ref: Building, Field: Solar Distribution).

However, if you do use the reflections option AND you are modeling a DaylightingDevice:Shelf or DaylightingDevice:Tubular, then you still need to enter some values of View Factor to Ground. For DaylightingDevice:Shelf you need to enter View Factor to Ground for the window associated with the shelf. And for DaylightingDevice:Tubular you need to enter the View Factor to Ground for the FenestrationSurface:Detailed corresponding to the dome of the tubular device.

Note 1: The corresponding view factor to the sky for diffuse solar radiation is not a user input; it is calculated within EnergyPlus based on surface orientation, sky solar radiance distribution, and shadowing surfaces.

Note 2: The view factors to the sky and ground for thermal infrared (long-wave) radiation are not user inputs; they are calculated within EnergyPlus based on surface tilt and shadowing surfaces. Shadowing surfaces are considered to have the same emissivity and temperature as the ground, so they are lumped together with the ground in calculating the ground IR view factor.

### 1.9.38.10 Field: Number of Vertices

This field specifies the number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on "Surface Vertices" above.

IDF example of three walls (first is an exterior wall, second and third are interzone partitions):

### 1.9.39 FenestrationSurface:Detailed

This surface class is used for subsurfaces, which can be of five different types: Windows, Doors, GlassDoors, TubularDaylightDomes, and TubularDaylightDiffusers. A subsurface (such as a window) of a base surface (such as a wall) inherits several of the properties (such as Outside Boundary Condition, Sun Exposure, etc.) of the base surface. Windows, GlassDoors, TubularDaylightDomes, and TubularDaylightDiffusers are considered to have one or more glass layers and so transmit solar radiation. Doors are considered to be opaque.

#### 1.9.39.1 Field: Name

This is a unique name associated with the heat transfer subsurface. It may be used in other places as a reference (e.g. as the opposing subsurface of an interzone window or door).

#### 1.9.39.2 Field: Surface Type

The choices for Surface Type are Window, Door, GlassDoor, TubularDaylightDome, and TubularDaylightDiffuser. Doors are assumed to be opaque (do not transmit solar radiation) whereas the other surface types do transmit solar radiation. Windows and Glass Doors are treated identically in the calculation of conduction heat transfer, solar gain, daylighting, etc. A Window or GlassDoor, but not a Door, can have a movable interior, exterior or between-glass shading device, such as blinds (ref: WindowMaterial:Blind object), and can have a frame and/or a divider (ref: WindowProperty:FrameAndDivider object). TubularDaylightDomes and TubularDaylightDomes are specialized subsurfaces for use with the DaylightingDevice:Tubular object to simulate Tubular Daylighting Devices (TDDs). TubularDaylightDomes and TubularDaylightDomes cannot have shades, screens or blinds. In the following, the term "window" applies to Window, GlassDoor, TubularDaylightDome, and TubularDaylightDome, if not otherwise explicitly mentioned.

As noted in the description of the BuildingSurface:Detailed, Azimuth (facing angle) and Tilt are calculated from the entered vertices. Tilts of subsurfaces will normally be the same as their base surface. If these are significantly beyond the "normals" for the base surface, warning messages may be issued. If the facing angles are not correct, you may have a window pointing "into" the zone rather than out of it – this would cause problems in the calculations. Note, too, that a "reveal" (inset or outset) may occur if the plane of the subsurface is not coincident with the base surface; the reveal has an effect on shading of the subsurface.

#### 1.9.39.3 Field: Construction Name

This is the name of the subsurface's construction (ref: Construction object [for Door] and Construction, Construction:ComplexFenestrationState, Construction:WindowDataFile objects [for Window and GlassDoor]).

For windows, if Construction Name is not found among the constructions on the input (.idf) file, the Window Data File (ref. Construction:WindowDataFile object) will be searched for that Construction Name (see "Importing Windows from WINDOW"). If that file is not present or if the Construction Name does not match the name of an entry on the file, an error will result. If there is a match, a window construction and its corresponding glass and gas materials will be created from the information read from the file.

#### 1.9.39.4 Field: Building Surface Name

This is the name of a surface that contains this subsurface. Certain kinds of surfaces may not be allowed to have subsurfaces. For example, a surface in contact with the ground (Outside Boundary Condition = Ground) cannot contain a window.

#### 1.9.39.5 Field: Outside Boundary Condition Object

If the base surface has Outside Boundary Condition = Surface or OtherSideCoefficients, then this field must also be specified for the subsurface. Otherwise, it can be left blank.

If the base surface has Outside Boundary Condition = Zone, then this surface retains that characteristic and uses the same zone of the base surface. It can be entered here for clarity or it can be left blank.

If Outside Boundary Condition for the base surface is Surface, this field should specify the subsurface in the opposing zone that is the counterpart to this subsurface. The constructions of the subsurface and opposing subsurface must match, except that, for multi-layer constructions, the layer order of the opposing subsurface's construction must be the reverse of that of the subsurface.

If Outside Boundary Condition for the base surface is OtherSideCoefficients, this field could specify the set of SurfaceProperty:OtherSideCoefficients for this subsurface. If this is left blank, then the Other Side Coefficients of the base surface will be used for this subsurface. *Windows and GlassDoors are not allowed to have Other Side Coefficients.*

#### 1.9.39.6 Field: View Factor to Ground

The fraction of the ground plane (assumed horizontal) that is visible from a heat-transfer surface. It is used to calculate the diffuse solar radiation from the ground that is incident on the surface.

For example, if there are no obstructions, a vertical surface sees half of the ground plane and so View Factor to Ground = 0.5. A horizontal downward-facing surface sees the entire ground plane, so View Factor to Ground = 1.0. A horizontal upward-facing surface (horizontal roof) does not see the ground at all, so View Factor to Ground = 0.0.

Unused if reflections option in Solar Distribution field in Building object input unless a Daylighting Device:Shelf or Daylighting Device:Tubular has been specified.

If you do not use the reflections option in the Solar Distribution field in your Building object input, you are responsible for entering the View Factor to Ground for each heat-transfer surface. Typical values for a surface that is not shadowed are obtained by the simple equation:

$$\text{View Factor to Ground} = (1 - \cos(\text{SurfTilt})) / 2$$

For example, this gives 0.5 for a wall of tilt 90°. If the tilt of the wall changes, then the View Factor to Ground must also change.

If you enter **autocalculate** in this field, EnergyPlus will automatically calculate the view factor to ground based on the tilt of the surface.

If **you do use the reflections option in the Solar Distribution field** in your BUILDING object input, you do **not** have to enter View Factor to Ground values. In this case the program will automatically calculate the value to use for each exterior surface taking into account solar shadowing (including shadowing of the ground by the building) and reflections from obstructions (ref: Building, Field: Solar Distribution).

However, if you do use the reflections option AND you are modeling a DaylightingDevice:Shelf or DaylightingDevice:Tubular, then you still need to enter some values of View Factor to Ground. For DaylightingDevice:Shelf you need to enter View Factor to Ground for the window associated with the shelf. And for DaylightingDevice:Tubular you need to enter the View Factor to Ground for the FenestrationSurface:Detailed corresponding to the dome of the tubular device (ref: DaylightingDevice:Tubular).

Note 1: The corresponding view factor to the sky for diffuse solar radiation is not a user input; it is calculated within EnergyPlus based on surface orientation, sky solar radiance distribution, and shadowing surfaces.

Note 2: The view factors to the sky and ground for thermal infrared (long-wave) radiation are not user inputs; they are calculated within EnergyPlus based on surface tilt and shadowing surfaces. Shadowing surfaces are considered to have the same emissivity and temperature as the ground, so they are lumped together with the ground in calculating the ground infrared view factor.

#### 1.9.39.7 Field: Shading Control Name

This field, if not blank, is the name of the window shading control (ref: WindowProperty:ShadingControl object) for this subsurface. It is used for Surface Type = Window and GlassDoor. To assign a shade to a window or glass door, see WindowMaterial:Shade. To assign a screen, see WindowMaterial:Screen. To assign a blind, see WindowMaterial:Blind. To assign switchable glazing, such as electrochromic glazing, see WindowProperty:ShadingControl.

#### 1.9.39.8 Field: Frame and Divider Name

This field, if not blank, can be used to specify window frame, divider and reveal-surface data (ref: WindowProperty:FrameAndDivider object). It is used only for exterior GlassDoors and rectangular exterior Windows, i.e., those with OutsideFaceEnvironment = Outdoors.

This field should be blank for triangular windows.

#### 1.9.39.9 Field: Multiplier

Used only for Surface Type = Window, Door or Glass Door. It is the number of identical items on the base surface. Using Multiplier can save input effort and calculation time. In the calculation the area (and area of frame and divider, if present and surface type is a window) is multiplied by Multiplier. The calculation of shadowing on the subsurfaces (and the calculation of the interior distribution of beam solar radiation transmitted by windows and glass doors) are done for the specified subsurface position and dimensions.

Multiplier should be used with caution. Multiplier > 1 can give inaccurate or nonsensical results in situations where the results are sensitive to window or glass door position. This includes shadowing on the window/glass door, daylighting from the window/glass door, and interior distribution of solar radiation from the window/glass door. In these cases, the results for the single input window/glass door, after multiplication, may not be representative of the results you would get if you entered each of the multiple subsurfaces separately.

If Multiplier > 1, you will get

--a *warning* if Solar Distribution = FullExterior or FullInteriorAndExterior (ref: Building - Field: Solar Distribution), indicating that the shadowing on the input window or the interior solar radiation distribution from the input window may not be representative of the actual group of windows. No warning is issued if Solar Distribution = MinimalShadowing.

--an *error* if the window is an exterior window/glass door in a zone that has a detailed daylighting calculation (Daylighting:Detailed specified for the zone). Since a single window with a multiplier can never give the same daylight illuminance as the actual set of windows, you are not allowed to use Multiplier in this situation.

### 1.9.39.10 Field: Number of Vertices

The number of sides the surface has (number of X,Y,Z vertex groups). For further information, see the discussion on “Surface Vertices” above. Door and GlassDoor subsurfaces are rectangular and therefore have four vertices. Window subsurfaces can be rectangular or triangular and therefore have four or three vertices, respectively.

### 1.9.39.11 Fields: Vertex Coordinates

This is a total of twelve fields giving the x,y,z coordinate values of the four vertices of rectangular subsurfaces [m], or a total of nine fields giving the x,y,z coordinate values of the three vertices of triangular windows.

For triangular windows the first vertex listed can be any of the three vertices, but the order of the vertices should be counter-clockwise if VertexEntry is CounterClockWise and clockwise if VertexEntry is ClockWise (ref: GlobalGeometryRules).

An IDF example of a rectangular subsurface (Window):

```

4.572000, 0.152000, 2.743000 ;
```

## 1.9.40 Window Modeling Options

The following table shows what input objects/fields to use to model different window options. It also gives the name of an example input, if available, that demonstrates the option.

Table 8. Window Modeling Options

Option	Object/Field or Output Variable	Input File (histributeh with install)
Build up a window from layers	WindowMaterial:Glazing, WindowMaterial:Gas, WindowMaterial:Shade, WindowMaterial:Screen, WindowMaterial:Blind, Construction	WindowTests.idf
Add an overhang	Shading:Zone:Detailed	5ZoneAirCooled.idf
Add a shading device	WindowMaterial:Shade, WindowMaterial:Screen or WindowMaterial:Blind; WindowProperty:ShadingControl	WindowTests.idf, PurchAirWindowBlind.idf
Control a shading device	WindowProperty:ShadingControl	PurchAirWindowBlind.idf
Determine when a shading device is on in a particular timestep	Print the variable “Surface Shading Device Is On Time Fraction”	PurchAirWindowBlind.idf
Control the slat angle of a blind	WindowProperty:ShadingControl	PurchAirWindowBlind.idf
Add a frame	WindowProperty:FrameAndDivider	PurchAirWithDaylighting.idf
Add a divider	WindowProperty:FrameAndDivider	PurchAirWithDaylighting.idf
Allow window to daylight a zone	Daylighting:Controls, Daylighting:DELIGHT:Controls	PurchAirWithDaylighting.idf, DELIGHT-Detailed-Comparison.idf
Find solar reflected onto window from neighboring buildings	Building/SolarDistribution field – uses “WithReflections”	ReflectiveAdjacentBuilding.idf
Model switchable glazing (e.g., electrochromic glass)	WindowProperty:ShadingControl	PurchAirWithDaylighting.idf

Add an interior window Track how beam solar falls on interior surfaces	Define two FenestrationSurface:Detailed's, one for each associated interior wall Building/Solar Distribution = FullInteriorAndExterior	PurchAirWithDoubleFacadeDaylighting.idf PurchAirWithDoubleFacadeDaylighting.idf
Track beam solar transmitted through interior windows	Building/Solar Distribution = FullInteriorAndExterior	PurchAirWithDoubleFacadeDaylighting.idf
Add a shading device on an interior window	Not allowed	
Model an airflow window (aka, heat extract window)	WindowProperty:AirflowControl	AirflowWindowsAndBetweenGlassBlinds.idf
Add a storm window glass layer	WindowProperty:StormWindow	StormWindow.idf
Add natural ventilation through an open window	Ventilation or AirflowNetwork objects (AirflowNetwork:Multizone:Surface, AirflowNetwork:MultiZone:Component:DetailedOpening, etc.)	AirflowNetwork3zvent.idf
Add diffusing glass	WindowMaterial:Glazing/Solar Diffusing = Yes	
Add dirt on window	WindowMaterial:Glazing/Dirt Correction Factor for Solar and Visible Transmittance	
Import window (and frame/divider if present) from WINDOW program	See "Importing Windows from WINDOW program"	
Find daylighting through interior windows	See "Double Facades: Daylighting through Interior Windows"	PurchAirWithDoubleFacadeDaylighting.idf
Determine when condensation occurs	Print the variables "Surface Window Inside Face Glazing Condensation Status," "Surface Window Inside Face Frame Condensation Status," "Surface Window Inside Face Divider Condensation Status"	

### 1.9.41 InternalMass

Any surface that would logically be described as an interior wall, floor or ceiling can just as easily be described as Internal Mass. Internal Mass surface types only exchange energy with the zone in which they are described; they do not see any other zones. There are two approaches to using internal mass. The first approach is to have several pieces of internal mass with each piece having a different construction type. The other approach is to choose an average construction type and combine all of the interior surfaces into a single internal mass. Similar to interior surfaces with an adiabatic boundary condition, the zone will only exchange energy with the inside of the Internal Mass construction. If both sides of the surface exchange energy with the zone then the user should input twice the area when defining the Internal Mass object. Note that furniture and other large objects within a zone can be described using internal mass. However, simplifying calculations using internal mass must be used with caution when the "FullInteriorAndExterior" or "FullInteriorAndExteriorWithReflections" Solar Distribution model (see Building parameters) is chosen.

#### 1.9.41.1 Example

When zoning an office building, five west-facing offices have been combined into one zone. All of the offices have interior walls made of the same materials. As shown in the figure below, this zone may be described with 5 exterior walls and 11 internal walls or 1 exterior wall and 1 internal mass. Note that fewer surfaces will speed up the EnergyPlus calculations.

Figure 30. Representing 11 internal walls as internal mass

#### 1.9.41.2 Example

A five-story building has the same ceiling/floor construction separating each of the levels. Zones that are on floors 2 through 4 may be described using a single piece of internal mass to represent both the floor and ceiling. The construction for this internal mass would be identical to the ceiling/floor construction that would be used to describe separate surfaces and the area of the internal mass surface would be the total surface area of the combined ceilings/floors (i.e. twice the total floor area).

#### 1.9.41.3 Field: Name

This is a unique character string associated with the internal mass surface. Though it must be unique from other surface names, it is used primarily for convenience with internal mass surfaces.

#### 1.9.41.4 Field: Construction Name

This is the name of the construction (ref: Construction object) used in the surface.

#### 1.9.41.5 Field: Zone Name

This is the name of the zone in which the internal mass is represented.

#### 1.9.41.6 Field: Surface Area

This field is the surface area of the internal mass. The area that is specified must be the entire surface area that is exposed to the zone. If both sides of a wall are completely within the same zone, then the area of both sides must be included when describing that internal wall.

IDF examples of Internal Mass surfaces:

```
InternalMass,Zn002:IntM001, !- Surface Name
  INTERIOR, !- Construction Name
  DORM ROOMS AND COMMON AREAS, !- Zone
  408.7734 ; !- Total area exposed to Zone {m2}
```

```
InternalMass,Zn002:IntM002, !- Surface Name
  PARTITION02, !- Construction Name
  DORM ROOMS AND COMMON AREAS, !- Zone
  371.6122 ; !- Total area exposed to Zone {m2}
```

### 1.9.42 Surface Output Variables/Reports

Note that Surface Outputs from specialized algorithms (such as Effective Moisture Penetration Depth (EMPD), Combined Heat and Moisture Transport (HAMT) and Conduction Finite Difference (CondFD) are discussed under the objects that describe the specialized inputs for these algorithms). You can access them via these links:

- [Moisture Penetration Depth \(EMPD\) Outputs](#)
- [Conduction Finite Difference \(CondFD\) Outputs](#)
- [Heat and Moisture \(HAMT\) Outputs](#)

Additionally, the output variables applicable to all heat transfer surfaces:

- [Zone,Sum,Surface Inside Face Heat Balance Calculation Iteration Count \[\]](#)
- [Zone,Average,Surface Inside Face Temperature \[C\]](#)
- [Zone,Average,Surface Outside Face Temperature \[C\]](#)
- [Zone,Average,Surface Inside Face Adjacent Air Temperature \[C\]](#)
- [Zone,Average,Surface Inside Face Convection Heat Transfer Coefficient \[W/m2-K\]](#)
- [Zone,Average,Surface Inside Face Convection Heat Gain Rate \[W\]](#)
- [Zone,Average,Surface Inside Face Convection Heat Gain Rate per Area \[W/m2\]](#)
- [Zone,Sum,Surface Inside Face Convection Heat Gain Energy \[J\]](#)

- Zone,Average, Surface Inside Face Beam Solar Radiation Heat Gain Rate [W]

### 1.9.43 Window Output Variables

Output variables applicable only to exterior windows and glass doors:

- Zone,Average,Zone Windows Total Transmitted Solar Radiation Rate [W]
- Zone,Sum,Zone Transmitted Solar Energy [J]
- Zone,Average,Zone Windows Total Heat Gain Rate [W]
- Zone,Sum,Zone Windows Total Heat Gain Energy [J]
- Zone,Average,Zone Windows Total Heat Loss Rate [W]
- Zone,Sum,Zone Windows Total Heat Loss Energy [J]
- Zone,Average,Zone Exterior Windows Total Transmitted Beam Solar Radiation Rate [W]
- Zone,Sum,Zone Exterior Windows Total Transmitted Beam Solar Radiation Energy [J]
- Zone,Average,Zone Interior Windows Total Transmitted Beam Solar Radiation Rate [W]
- Zone,Sum,Zone Interior Windows Total Transmitted Beam Solar Radiation Energy [J]
- Zone,Average,Zone Exterior Windows Total Transmitted Diffuse Solar Radiation Rate [W]
- Zone,Sum,Zone Exterior Windows Total Transmitted Diffuse Solar Radiation Energy [J]
- Zone,Average,Zone Interior Windows Total Transmitted Diffuse Solar Radiation Rate [W]
- Zone,Average,Surface Window Total Glazing Layers Absorbed Solar Radiation Rate [W]
- Zone,Average,Surface Window Total Glazing Layers Absorbed Shortwave Radiation Rate [W]
- Zone,Sum,Surface Window Total Glazing Layers Absorbed Solar Radiation Energy [J]
- Zone,Average,Surface Window Shading Device Absorbed Solar Radiation Rate [W]
- Zone,Sum,Surface Window Shading Device Absorbed Solar Radiation Energy [J]
- Zone,Average, Surface Window Transmitted Solar Radiation Rate [W]
- Zone,Sum,Surface Window Transmitted Solar Radiation Energy [J]
- Zone,Average,Surface Window Transmitted Beam Solar Radiation Rate [W]
- Zone,Average,Surface Window Transmitted Beam To Beam Solar Radiation Rate [W]
- Zone,Average,Surface Window Transmitted Beam To Diffuse Solar Radiation Rate [W]
- Zone,Sum,Surface Window Transmitted Beam Solar Radiation Energy [J]
- Zone,Sum,Surface Window Transmitted Beam To Beam Solar Radiation Energy [J]
- Zone,Sum,Surface Window Transmitted Beam To Diffuse Solar Radiation Energy [J]

- Zone,Average,Surface Window Transmitted Diffuse Solar Radiation Rate [W]
- Zone,Sum,Surface Window Transmitted Diffuse Solar Radiation Energy [J]
- Zone,Average,Surface Window System Solar Transmittance []
- Zone,Average,Surface Window System Solar Absorptance []
- Zone,Average,Surface Window System Solar Reflectance []
- Zone,Average,Surface Window Gap Convective Heat Transfer Rate [W]
- Zone,Sum,Surface Window Gap Convective Heat Transfer Energy [J]
- Zone,Average,Surface Window Heat Gain Rate [W]
- Zone,Sum,Surface Window Heat Gain Energy [J]
- Zone,Average,Surface Window Heat Loss Rate [W]
- Zone,Sum,Surface Window Heat Loss Energy [J]
- Zone,Average,Surface Window Glazing Beam to Beam Solar Transmittance[]
- Zone,Average,Surface Window Glazing Beam to Diffuse Solar Transmittance []
- Zone,Average,Surface Window Glazing Diffuse to Diffuse Solar Transmittance[]
- Zone,Average,Surface Window Model Solver Iteration Count []
- Zone,Average,Surface Window Solar Horizontal Profile Angle[deg]
- Zone,Average,Surface Window Solar Vertical Profile Angle[deg]
- Zone,Average,Surface Window Outside Reveal Reflected Beam Solar Radiation Rate [W]
- Zone,Sum,Surface Window Outside Reveal Reflected Beam Solar Radiation Energy
- Zone,Average,Surface Window Inside Reveal Reflected Beam Solar Radiation Rate [W]
- Zone,Sum,Surface Window Inside Reveal Reflected Beam Solar Radiation Energy [J]
- Zone,Average,Surface Window Inside Reveal Absorbed Beam Solar Radiation Rate [W]
- Zone,Average,Surface Window Inside Face Glazing Condensation Status []
- Zone,Average,Surface Window Inside Face Frame Condensation Status []
- Zone,Average,Surface Window Inside Face Divider Condensation Status []
- Zone,Average,Surface Shading Device Is On Time Fraction[]
- Zone,Average,Surface Window Blind Slat Angle [deg]
- Zone,Average,Surface Window Blind Beam to Beam Solar Transmittance[]
- Zone,Average,Surface Window Blind Beam to Diffuse Solar Transmittance[]
- Zone,Average,Surface Window Blind Diffuse to Diffuse Solar Transmittance[]
- Zone,Average,Surface Window Blind and Glazing System Beam Solar Transmittance[]
- Zone,Average,Surface Window Blind and Glazing System Diffuse Solar Transmittance[]
- Zone,Average,Surface Window Screen Beam to Beam Solar Transmittance []
- Zone,Average,Surface Window Screen Beam to Diffuse Solar Transmittance []
- Zone,Average,Surface Window Screen Diffuse to Diffuse Solar Transmittance []
- Zone,Average,Surface Window Screen and Glazing System Beam Solar Transmittance []
- Zone,Average,Surface Window Screen and Glazing System Diffuse Solar Transmittance []
- Zone,State,Surface Storm Window On Off Status []

- Zone,Average,Surface Window Inside Face Frame and Divider Zone Heat Gain Rate [W]
- Zone,Average,Surface Window Frame Heat Gain Rate [W]
- Zone,Average,Surface Window Frame Heat Loss Rate [W]
- Zone,Average,Surface Window Divider Heat Gain Rate [W]
- Zone,Average,Surface Window Divider Heat Loss Rate [W]
- Zone,Average,Surface Window Frame Inside Temperature [C]
- Zone,Average,Surface Window Frame Outside Temperature [C]
- Zone,Average,Surface Window Divider Inside Temperature [C]
- Zone,Average,Surface Window Divider Outside Temperature [C]

If the user requests to display advanced report/output variables (e.g. see Output:Diagnostics keyword DisplayAdvancedReportVariables) the the following additional output variables are available for exterior windows and glass doors

- Zone,Average,Surface Window Inside Face Glazing Zone Convection Heat Gain Rate [W]
- Zone,Average,Surface Window Inside Face Glazing Net Infrared Heat Transfer Rate [W]
- Zone,Average,Surface Window Shortwave from Zone Back Out Window Heat Transfer Rate [W]
- Zone,Average,Surface Window Inside Face Frame and Divider Zone Heat Gain Rate [W]
- Zone,Average,Surface Window Inside Face Gap between Shade and Glazing Zone Convection Heat Gain Rate [W]
- Zone,Average,Surface Window Inside Face Shade Zone Convection Heat Gain Rate [W]
- Zone,Average,Surface Window Inside Face Shade Net Infrared Heat Transfer Rate [W]

Output variables applicable only to interior windows and glass doors:

- Zone,Average, Surface Window Transmitted Beam Solar Radiation Rate [W]
- Zone,Sum,Surface Window Transmitted Beam Solar Radiation Energy [J]

If the user requests to display advanced report/output variables (e.g. see Output:Diagnostics keyword DisplayAdvancedReportVariables) the the following additional output variable is available for Equivalent Layer Window;

- Zone,Average, Surface Window Inside Face Other Convection Heat Gain Rate [W]
- Output variables applicable to interior and exterior windows and doors are:
- Zone,Average,Surface Window Total Absorbed Shortwave Radiation Rate Layer <x> [W]
- Zone,Average,Surface Window Front Face Temperature Layer <x> [C]
- Zone,Average,Surface Window Back Face Temperature Layer <x> [C]

#### **1.9.43.1 Surface Window Total Absorbed Shortwave Radiation Rate Layer <x> [W]**

This will output shortwave radiation absorbed in a window layer. The key values for this output variable are the surface name. Layers are numbered from the outside to the inside of the surface. The full listing will appear in the RDD file.

#### **1.9.43.2 Surface Window Front Face Temperature Layer <x> [C]**

This will output a temperature for the front face of the layer. The layer front face is considered to be the face closest to the outside environment. The full listing will appear in the RDD file.

#### **1.9.43.3 Surface Window Back Face Temperature Layer <x> [C]**

This will output a temperature for the back face of the layer. The layer back face is considered to be the face closest to the inside environment. The full listing will appear in the RDD file.

#### **1.9.44 Surface Output Variables (all heat transfer surfaces)**

The various output variables related to surface heat transfer are organized around the inside and outside face of each surface. The zone heat balance model draws energy balances at each side, or face, of a surface and so each surface essentially has two sets of results. The inside face is the side of a heat transfer

surface that faces toward the thermal zone. The outside face is the side of a heat transfer surface that faces away from the thermal zone, typically facing outdoors. The Key Value for these is generally the user-defined name of the surface.

#### **1.9.44.1 Surface Inside Face Heat Balance Calculation Iteration Count []**

This output is the number of iterations used in a part of the solution for surface heat transfer that accounts for thermal radiation heat transfer between zone surfaces. This is simply a counter on the iteration loop for inside face surface modeling. There is only one instance of this output in a given run and the Key Value is "Simulation."

#### **1.9.44.2 Surface Inside Face Temperature [C]**

This is the temperature of the surface's inside face, in degrees Celsius. Former Name: Prior to version 7.1 this output was called Surface Inside Temperature.

#### **1.9.44.3 Surface Outside Face Temperature [C]**

This is the temperature of the surface's outside face, in degrees Celsius. Former Name: Prior to version 7.1, this output was called Surface Outside Temperature.

#### **1.9.44.4 Surface Inside Face Adjacent Air Temperature [C]**

This is the effective bulk air temperature used for modeling the inside surface convection heat transfer. This is the same as the zone mean air temperature when using the mixing model for roomair. However, if more advanced roomair models are used, this variable will report the air temperature predicted by the roomair model as it was used in the surface heat balance model calculations. Former Name: Prior to version 7.1, this output was called Surface Int Adjacent Air Temperature.

#### **1.9.44.5 Surface Inside Face Convection Heat Gain Rate [W]**

#### **1.9.44.6 Surface Inside Face Convection Heat Gain Rate per Area [W/m2]**

#### **1.9.44.7 Surface Inside Face Convection Heat Gain Energy [J]**

These "inside face convection heat gain" output variables describe the heat transferred by convection between the inside face and the zone air. The values can be positive or negative with positive indicating heat is being added to the surface's face by convection. Different versions of the report are available including the basic heat gain rate (W), and a per unit area flux (W/m2), and an energy version (J).

Former Name: Prior to version 7.1, these outputs were called "Surface Int Convection Heat \* " and had used the opposite sign convention.

#### **1.9.44.8 Surface Inside Face Convection Heat Transfer Coefficient [W/m2-K]**

This is the coefficient that describes the convection heat transfer. It is the value of "Hc" in the classic convection model  $Q = Hc * A * (T - T_s)$ . This is the result of the surface convection algorithm used for the inside face. Former Name: Prior to version 7.1, this output was called "Surface Int Convection Coeff."

#### **1.9.44.9 Surface Inside Face Net Surface Thermal Radiation Heat Gain Rate [W]**

#### **1.9.44.10 Surface Inside Face Net Surface Thermal Radiation Heat Gain Rate per Area [W/m2]**

#### **1.9.44.11 Surface Inside Face Net Surface Thermal Radiation Heat Gain Energy [J]**

These "inside face net surface thermal radiation heat gain" output variables describe the heat transferred by longwave infrared thermal radiation exchanges between the inside faces of other surfaces in the zone. The values can be positive or negative with positive indicating heat is being added to the surface's face by thermal radiation. Different versions of the report are available including the basic heat gain rate (W), and a per unit area flux (W/m2), and an energy version (J).

#### **1.9.44.12 Surface Inside Face Solar Radiation Heat Gain Rate [W]**

#### **1.9.44.13 Surface Inside Face Solar Radiation Heat Gain Rate per Area [W/m2]**

#### **1.9.44.14 Surface Inside Face Solar Radiation Heat Gain Energy [J]**

These "inside face solar radiation heat gain" output variables describe the heat transferred by solar radiation onto the inside face. The values are always positive and indicate heat is being added to the surface's face by solar radiation. This is sunlight that has entered the zone through a window and been absorbed on the inside face of the surface. Different versions of the report are available including the basic heat gain rate (W), and a per unit area flux (W/m2), and an energy version (J).

#### **1.9.44.15 Surface Inside Face Lights Radiation Heat Gain Rate [W]**

#### **1.9.44.16 Surface Inside Face Lights Radiation Heat Gain Rate per Area [W/m2]**

#### **1.9.44.17 Surface Inside Face Lights Radiation Heat Gain Energy [J]**

These “inside face lights radiation heat gain” output variables describe the heat transferred by shortwave radiation onto the inside face. The values are always positive and indicate heat is being added to the surface’s face by shortwave radiation that emanated from electric lighting equipment and was absorbed by the surface. Different versions of the report are available including the basic heat gain rate (W), and a per unit area flux (W/m2), and an energy version (J).

#### **1.9.44.18 Surface Inside Face Internal Gains Radiation Heat Gain Rate [W]**

#### **1.9.44.19 Surface Inside Face Internal Gains Radiation Heat Gain Rate per Area [W/m2]**

#### **1.9.44.20 Surface Inside Face Internal Gains Radiation Heat Gain Energy [J]**

These “inside face internal gains radiation heat gain” output variables describe the heat transferred by longwave infrared thermal radiation onto the inside face that emanated from internal gains such as lights, electric equipment, and people. The values are always positive and indicate heat is being added to the surface’s face by the absorption of longwave thermal radiation. Different versions of the report are available including the basic heat gain rate (W), and a per unit area flux (W/m2), and an energy version (J).

#### **1.9.44.21 Surface Inside Face System Radiation Heat Gain Rate [W]**

#### **1.9.44.22 Surface Inside Face System Radiation Heat Gain Rate per Area [W/m2]**

#### **1.9.44.23 Surface Inside Face System Radiation Heat Gain Energy [J]**

These “inside face system radiation heat gain” output variables describe the heat transferred by infrared thermal radiation onto the inside face that emanated from HVAC equipment such as baseboard heaters or high-temperature radiant heating panels. The values are always positive and indicate heat is being added to the surface’s face by the absorption of thermal radiation. Different versions of the report are available including the basic heat gain rate (W), and a per unit area flux (W/m2), and an energy version (J).

#### **1.9.44.24 Surface Outside Face Convection Heat Gain Rate [W]**

#### **1.9.44.25 Surface Outside Face Convection Heat Gain Rate per Area [W/m2]**

#### **1.9.44.26 Surface Outside Face Convection Heat Gain Energy [J]**

These “outside face convection” output variables describe heat transferred by convection between the outside face and the surrounding air. The values can be positive or negative with positive values indicating heat is added to the surface face by convection heat transfer. Different versions of the report are available including the basic heat gain rate (W), and a per unit area flux (W/m<sup>2</sup>), and an energy version (J).

Former Name: Prior to version 7.1, these outputs were called “Surface Ext Convection Heat \*\*” and used the opposite sign convention.

#### **1.9.44.27 Surface Outside Face Convection Heat Transfer Coefficient [W/m2-K]**

This is the coefficient that describes the convection heat transfer. It is the value of “Hc” in the classic convection model  $Q = Hc \cdot A \cdot (T - T_s)$ . This is the result of the surface convection algorithm used for the outside face. Former Name: Prior to Version 7.1, this output was called “Surface Ext Convection Coeff.”

#### **1.9.44.28 Surface Outside Face Net Thermal Radiation Heat Gain Rate [W]**

#### **1.9.44.29 Surface Outside Face Net Thermal Radiation Heat Gain Rate per Area [W/m2]**

#### **1.9.44.30 Surface Outside Face Net Thermal Radiation Heat Gain Energy [J]**

These “outside face net thermal radiation” output variables describe the heat transferred by longwave infrared thermal radiation exchanges between the surface and the surroundings of the outside face. This is the net of all forms of longwave thermal infrared radiation heat transfer. The values can be positive or negative with positive indicating the net addition of heat to the outside face. Different versions of the report are available including the basic heat gain rate (W), and a per unit area flux (W/m2), and an energy version (J).

Former Name: Prior to version 7.1, these outputs were called “Surface Ext Thermal Radiation Heat \*\*” and used the opposite sign convention.

#### **1.9.44.31 Surface Inside Face Exterior Windows Incident Beam Solar Radiation Rate [W]**

#### **1.9.44.32 Surface Inside Face Exterior Windows Incident Beam Solar Radiation Rate per Area [W/m2]**

#### **1.9.44.33 Surface Inside Face Exterior Windows Incident Beam Solar Radiation Energy [J]**

Beam solar radiation from the exterior windows in a zone incident on the inside face of a surface in the zone. If Solar Distribution in the BUILDING object is equal to MinimalShadowing or FullExterior, it is assumed that all beam solar from exterior windows falls on the floor. In this case the value of this output variable can be greater than zero only for floor surfaces. If Solar Distribution equals FullInteriorExterior the program tracks where beam solar from exterior windows falls inside the zone, in which case the value of this variable can be greater than zero for floor as well as wall surfaces. Different versions of the report are available including

the basic incident rate (W), a per unit area flux (W/m<sup>2</sup>), and an energy version (J).

#### 1.9.44.34

#### 1.9.44.35 Surface Inside Face Interior Windows Incident Beam Solar Radiation Rate [W]

#### 1.9.44.36 Surface Inside Face Interior Windows Incident Beam Solar Radiation Rate per Area [W/m<sup>2</sup>]

#### 1.9.44.37 Surface Inside Face Interior Windows Incident Beam Solar Radiation Energy [J]

Beam solar radiation from the interior (i.e., interzone) windows in a zone incident on the inside face of a surface in the zone. This value is calculated only if Solar Distribution in the BUILDING object is equal to FullInteriorExterior. However, the program does not track where this radiation falls. Instead, it is treated by the program as though it were diffuse radiation uniformly distributed over all of the zone surfaces. See **Figure 31**. Different versions of the report are available including the basic incident rate (W), a per unit area flux (W/m<sup>2</sup>), and an energy version (J).

Figure 31. Beam solar radiation entering a zone through an interior window is distributed inside the zone as though it were diffuse radiation.

#### 1.9.44.38 Surface Inside Face Initial Transmitted Diffuse Absorbed Solar Radiation Rate [W]

As of Version 2.1, diffuse solar transmitted through exterior and interior windows is no longer uniformly distributed. Instead, it is distributed according to the approximate view factors between the transmitting window and all other heat transfer surfaces in the zone. This variable is the amount of transmitted diffuse solar that is initially absorbed on the inside of each heat transfer surface. The portion of this diffuse solar that is reflected by all surfaces in the zone is subsequently redistributed uniformly to all heat transfer surfaces in the zone, along with interior reflected beam solar and shortwave radiation from lights. The total absorbed shortwave radiation is given by the next variable.

#### 1.9.44.39 Surface Inside Face Absorbed Shortwave Radiation Rate [W]

As of Version 2.1, the previous variable plus absorbed shortwave radiation from uniformly distributed initially-reflected diffuse solar, reflected beam solar, and shortwave radiation from lights. This sum is the power of all sources of solar and visible radiation absorbed by the surface at the inside face.

### 1.9.45 Surface Output Variables (exterior heat transfer surfaces)

#### 1.9.45.1 Surface Outside Face Outdoor Air Drybulb Temperature [C]

The outdoor air dry-bulb temperature calculated at the height above ground of the surface centroid. Former Name: Prior to version 7.1, this output was called "Surface Ext Outdoor Dry Bulb."

#### 1.9.45.2 Surface Outside Face Outdoor Air Wetbulb Temperature [C]

The outdoor air wet-bulb temperature calculated at the height above ground of the surface centroid. Former Name: Prior to version 7.1, this output was called "Surface Ext Outdoor Wet Bulb."

#### 1.9.45.3 Surface Outside Face Outdoor Air Wind Speed [m/s]

The outdoor wind speed calculated at the height above ground of the surface centroid. Former Name: Prior to version 7.1, this output was called "Surface Ext Wind Speed."

#### 1.9.45.4 Surface Outside Face Sunlit Area [m<sup>2</sup>]

The outside area of an exterior surface that is illuminated by (unreflected) beam solar radiation.

#### 1.9.45.5 Surface Outside Face Sunlit Fraction []

The fraction of the outside area of an exterior surface that is illuminated by (unreflected) beam solar radiation. Equals Surface Outside Face Sunlit Area divided by total surface area.

#### 1.9.45.6 Surface Outside Face Thermal Radiation to Air Heat Transfer Coefficient [W/m<sup>2</sup>-K]

This is the coefficient that describes thermal radiation heat transfer between the outside face and the air mass surrounding the surface. It is the value of "Hr" in the classic linearized model for thermal radiation  $Q = Hr * A * (T_{surf} - T_{surf,db})$  when applied to the ambient air. Where  $T_{surf}$  = Surface Outside Face Temperature, and  $T_{surf,db}$  = Surface Outside Face Outdoor Air Drybulb Temperature. Former Name: Prior to version 7.1, this output was called "Surface Ext Rad to Air Coeff."

#### 1.9.45.7 Surface Outside Face Thermal Radiation to Sky Heat Transfer Coefficient [W/m<sup>2</sup>-K]

This is the coefficient that describes thermal radiation heat transfer between the outside face and the sky surrounding the surface. It is the value of “Hr” in the classic linearized model for thermal radiation  $Q = Hr * A * (T_{surf} - T_{sky})$  when applied to the sky. Where  $T_{surf}$  = Surface Outside Face Temperature, and  $T_{sky}$  = Site Sky Temperature. Former Name: Prior to version 7.1, this output was called “Surface Ext Rad to Sky Coeff.”

#### **1.9.45.8 Surface Outside Face Thermal Radiation to Ground Heat Transfer Coefficient [W/m2-K]**

This is the coefficient that describes thermal radiation heat transfer between the outside face and the ground surrounding the surface. It is the value of “Hr” in the classic linearized model for thermal radiation  $Q = Hr * A * (T_{surf} - T_{odb})$  when applied to the ground. Where  $T_{surf}$  = Surface Outside Face Temperature, and  $T_{odb}$  = Site Outdoor Air Drybulb Temperature (used as an approximation for the ground surface temperature). Former Name: Prior to version 7.1, this output was called “Surface Ext Rad to Ground Coeff.”

#### **1.9.45.9 Surface Outside Face Solar Radiation Heat Gain Rate [W]**

#### **1.9.45.10 Surface Outside Face Solar Radiation Heat Gain Rate per Area [W/m2]**

#### **1.9.45.11 Surface Outside Face Solar Radiation Heat Gain Energy [J]**

These “outside face solar radiation” output variables describe the heat transferred by the absorption of solar radiation at the outside face. This is the result of incident solar radiation being absorbed at the surface face. The values are always positive.

#### **1.9.45.12 Surface Outside Face Incident Solar Radiation Rate per Area [W/m2]**

The total solar radiation incident on the outside of an exterior surface. It is the sum of:

- Surface Outside Face Incident Beam Solar Radiation Rate per Area
- Surface Outside Face Incident Sky Diffuse Solar Radiation Rate per Area
- Surface Outside Face Incident Ground Diffuse Solar Radiation Rate per Area
- Surface Outside Face Incident Sky Diffuse Surface Reflected Solar Radiation Rate per Area
- Surface Outside Face Incident Beam To Beam Surface Reflected Solar Radiation Rate per Area
- Surface Outside Face Incident Sky Diffuse Surface Reflected Solar Radiation Rate per Area

#### **1.9.45.13 Surface Outside Face Incident Beam Solar Radiation Rate per Area [W/m2]**

The solar beam radiation incident on the outside of an exterior surface, including the effects of shadowing, if present. The beam here is that directly from the sun; it excludes beam specularly reflected from obstructions.

#### **1.9.45.14 Surface Outside Face Incident Sky Diffuse Solar Radiation Rate per Area [W/m2]**

The solar diffuse radiation from the sky incident on the outside of an exterior surface, including the effects of shadowing, if present.

#### **1.9.45.15 Surface Outside Face Incident Ground Diffuse Solar Radiation Rate per Area [W/m2]**

The solar diffuse radiation incident on the outside of an exterior surface that arises from reflection of beam solar and sky diffuse solar from the ground. This is the sum of the next two output variables, “Surface Outside Face Incident Beam To Diffuse Ground Reflected Solar Radiation Rate per Area” and “Surface Outside Face Incident Sky Diffuse Ground Reflected Solar Radiation Rate per Area.” The reflected solar radiation from the ground is assumed to be diffuse and isotropic (there is no specular component).

If “Reflections” option is not chosen in the Solar Distribution Field in the BUILDING object, the effects of shadowing are accounted for by the user-specified value of View Factor to Ground for the surface. If “Reflections” option is chosen, the program determines the effects of shadowing, including time-varying shadowing of the ground plane by the building itself.

#### **1.9.45.16 Surface Outside Face Incident Beam To Diffuse Ground Reflected Solar Radiation Rate per Area [W/m2]**

The solar diffuse radiation incident on the outside of an exterior surface that arises from beam-to-diffuse reflection from the ground. It is assumed that there is no beam-to-beam (specular) component. The beam here is that directly from the sun; it excludes beam specularly reflected from obstructions.

#### **1.9.45.17 Surface Outside Face Incident Sky Diffuse Ground Reflected Solar Radiation Rate per Area [W/m2]**

The solar diffuse radiation incident on the outside of an exterior surface that arises from sky diffuse solar reflection from the ground. The sky diffuse here is that directly from the sky; it excludes reflection of sky diffuse from obstructions.

#### **1.9.45.18 Surface Outside Face Incident Sky Diffuse Surface Reflected Solar Radiation Rate per Area [W/m2]**

The solar diffuse radiation incident on the outside of an exterior surface that arises from sky diffuse reflection from one or more obstructions. This value will be

non-zero only if “Reflections” option is chosen in the BUILDING object.

#### **1.9.45.19 Surface Outside Face Incident Beam To Beam Surface Reflected Solar Radiation Rate per Area [W/m2]**

The solar beam radiation incident on the outside of an exterior surface that arises from beam-to-beam (specular) reflection from one or more obstructions. This value will be non-zero only if “Reflections” option is chosen in the BUILDING object. For windows, the program treats this beam radiation as diffuse radiation in calculating its transmission and absorption.

#### **1.9.45.20 Surface Outside Face Incident Beam To Diffuse Surface Reflected Solar Radiation Rate per Area [W/m2]**

The solar diffuse radiation incident on the outside of an exterior surface that arises from beam-to-diffuse reflection from building shades or building surfaces. This value will be non-zero only if “Reflections” option is chosen in the BUILDING object.

#### **1.9.45.21 Surface Outside Face Beam Solar Incident Angle Cosine Value []**

The cosine of the angle of incidence of (unreflected) beam solar radiation on the outside of an exterior surface. The value varies from 0.0 for beam parallel to the surface (incidence angle =  $90^\circ$ ) to 1.0 for beam perpendicular to the surface (incidence angle =  $0^\circ$ ). Negative values indicate the sun is behind the surface, i.e. the surface does not see the sun.

#### **1.9.45.22 Surface Anisotropic Sky Multiplier []**

This is the view factor multiplier for diffuse sky irradiance on exterior surfaces taking into account the anisotropic radiance of the sky. The diffuse sky irradiance on a surface is given by Anisotropic Sky Multiplier \* Diffuse Solar Irradiance.

#### **1.9.45.23 Surface Window BSDF Beam Direction Number []**

#### **1.9.45.24 Surface Window BSDF Beam Phi Angle [rad]**

#### **1.9.45.25 Surface Window BSDF Beam Theta Angle [rad]**

### **1.9.46 Opaque Surface Output Variables**

The following variables apply only to opaque surfaces, where an opaque surface is considered here to be an exterior or interzone heat transfer surface of class FLOOR, WALL, ROOF or DOOR. **Note – these are advanced variables – you must read the descriptions and understand before use – then you must use the Output:Diagnosics object to allow reporting.**

#### **1.9.46.1 Surface Inside Face Conduction Heat Transfer Rate [W]**

#### **1.9.46.2 Surface Inside Face Conduction Heat Transfer Rate per Area [W/m2]**

#### **1.9.46.3 Surface Inside Face Conduction Heat Gain Rate [W]**

#### **1.9.46.4 Surface Inside Face Conduction Heat Loss Rate [W]**

These “inside face conduction” output variables describe heat flow by conduction right at the inside face of an opaque heat transfer surface. A positive value means that the conduction is from just inside the inside face toward the inside face. A negative value means that the conduction is from the inside face into the core of the heat transfer surface.

Note that Inside Face Conduction, when positive, does **not** indicate the heat flow from the surface to the zone air, which is governed by the inside face convection coefficient and the difference in temperature between the inside face and the zone air.

Different versions of the reports are available. The basic heat gain rate (W) and a per unit area flux ( $W/m^2$ ) can have positive or negative values with the sign convention that positive indicates heat flowing toward the face itself. There are also directed “gain” and “loss” versions that have only positive values or zero when the heat flow direction opposes.

Former Name: Prior to version 7.1, these outputs were called “Opaque Surface Inside Face Conduction \*.”

Former Name: For Conduction Finite Difference simulations (CondFD), CondFD Inside Surface Heat Flux is replaced with Surface Inside Face Conduction Heat Transfer Rate Per Area. Likewise for CondFD Inside Heat Flux to Surface.

#### **1.9.46.5 Surface Outside Face Conduction Heat Transfer Rate [W]**

#### **1.9.46.6 Surface Outside Face Conduction Heat Transfer Rate per Area [W/m2]**

#### **1.9.46.7 Surface Outside Face Conduction Heat Gain Rate [W]**

#### **1.9.46.8 Surface Outside Face Conduction Heat Loss Rate [W]**

These “outside face conduction” output variables describe heat flow by conduction right at the outside face of an opaque heat transfer surface. A positive value means that the conduction is from just inside the outside face toward the outside face. A negative value means that the conduction is from the outside face into the core of the heat transfer surface.

Note that outside face conduction, when positive, does **not** indicate the heat flow from the surface to the surrounding air, which is governed by the outside face convection coefficient and the difference in temperature between the inside face and the surrounding air.

Different versions of the reports are available. The basic heat transfer rate (W) and a per unit area flux (W/m<sup>2</sup>) can have positive or negative values with the sign convention that positive indicates heat flowing toward the face itself. There are also directed “gain” and “loss” versions that have only positive values or zero when the heat flow direction opposes.

Former Name: For Conduction Finite Difference simulations (CondFD), CondFD Outside Surface Heat Flux is replaced with Surface Outside Face Conduction Heat Transfer Rate Per Area. Likewise for CondFD Outside Heat Flux to Surface.

#### **1.9.46.9 Surface Average Face Conduction Heat Transfer Rate [W]**

#### **1.9.46.10 Surface Average Face Conduction Heat Transfer Rate per Area [W/m<sup>2</sup>]**

#### **1.9.46.11 Surface Average Face Conduction Heat Gain Rate [W]**

#### **1.9.46.12 Surface Average Face Conduction Heat Loss Rate [W]**

#### **1.9.46.13 Surface Average Face Conduction Heat Transfer Energy [J]**

These “average face conduction” output variables combine the inside face conduction and outside face conduction reports together to describe the conduction situation in a heat transfer surface in a nominal way. This is simply the average of the inside and outside face conduction rates, but with the sign convention for the outside face switched to match the inside face so that positive values here indicate heat flowing into the thermal zone.

Different versions of the reports are available. The basic heat conduction rate (W) and a per unit area flux (W/m<sup>2</sup>) can have positive or negative values with the sign convention that positive indicates heat flowing toward the thermal zone. There are also directed “gain” and “loss” versions that have only positive values or zero when the heat flow direction opposes (W). Finally there is a version for total energy transfer (J).

#### **1.9.46.14 Surface Heat Storage Rate [W]**

#### **1.9.46.15 Surface Heat Storage Rate per Area [W/m<sup>2</sup>]**

#### **1.9.46.16 Surface Heat Storage Gain Rate [W]**

#### **1.9.46.17 Surface Heat Storage Loss Rate [W]**

#### **1.9.46.18 Surface Heat Storage Energy [J]**

These “heat storage” output variables combine the inside face conduction and outside face conduction reports together to describe the thermal storage situation in a heat transfer surface in a nominal way. This is simply the difference between the inside and outside face conduction, but with the sign convention arranged so that positive values indicate heat being added to the core of the surface.

Different versions of the reports are available. The basic heat storage rate (W) and a per unit area flux (W/m<sup>2</sup>) can have positive or negative values with the sign convention that positive indicates heat being added to the surface’s mass. There are also directed “gain” and “loss” versions that have only positive values or zero when the heat storage direction opposes (W). Finally there is a version for total energy stored (J).

#### **1.9.46.19 Surface Internal Source Location Temperature [C]**

When a surface has an internal source or sink (defined using Construction:InternalSource) then this output is available for the temperature within the surface at the location of the source/sink.

#### **1.9.46.20 Zone Opaque Surface Inside Face Conduction [W]**

The sum of the Opaque Surface Inside Face Conduction values for all opaque surfaces in a zone for both positive and negative sums. For example, assume a zone has six opaque surfaces with Opaque Surface Inside Face Conduction values of 100, -200, 400, 50, 150 and -300 W. Then Zone Opaque Surface Inside Face Conduction = 700 - 500 = 200 W. Or if a zone has six opaque surfaces with Opaque Surface Inside Face Conduction values of -100, -200, 400, -50, 150 and -300W. Then Zone Opaque Surface Inside Face Conduction = 550 - 650 = -100 W.

#### **1.9.46.21 Zone Opaque Surface Inside Faces Total Conduction Heat Gain Rate [W]**

#### **1.9.46.22 Zone Opaque Surface Inside Faces Total Conduction Heat Gain Energy [J]**

These are the power and energy sums for the Opaque Surface Inside Face Conduction values for all opaque surfaces in a zone when that sum is positive. For example, assume a zone has six opaque surfaces with Opaque Surface Inside Face Conduction values of 100, -200, 400, 50, 150 and -300 W. Then Zone

Opaque Surface Inside Faces Total Conduction Heat Gain Rate =  $700 - 500 = 200$  W.

#### **1.9.46.23 Zone Opaque Surface Inside Faces Total Conduction Heat Loss Rate [W]**

#### **1.9.46.24 Zone Opaque Surface Inside Faces Total Conduction Heat Loss Energy [J]**

These are the power and energy absolute value for the sums of the Opaque Surface Inside Face Conduction values for all opaque surfaces in a zone when that sum is negative. For example, assume a zone has six opaque surfaces with Opaque Surface Inside Face Conduction values of -100, -200, 400, -50, 150 and -300W. Then Zone Opaque Surface Inside Faces Total Conduction Heat Loss Rate =  $|550 - 650| = |-100| = 100$  W.

#### **1.9.46.25 Zone Opaque Surface Outside Face Conduction [W]**

The sum of the Opaque Surface Outside Face Conduction values for all opaque surfaces in a zone for both positive and negative sums. For example, assume a zone has six opaque surfaces with Opaque Surface Outside Face Conduction values of 100, -200, 400, 50, 150 and -300 W. Then Zone Opaque Surface Outside Face Conduction =  $700 - 500 = 200$  W. Or if a zone has six opaque surfaces with Opaque Surface Outside Face Conduction values of -100, -200, 400, -50, 150 and -300W. Then Zone Opaque Surface Outside Face Conduction =  $550 - 650 = -100$  W.

#### **1.9.46.26 Zone Opaque Surface Outside Face Conduction Gain [W]**

#### **1.9.46.27 Zone Opaque Surface Outside Face Conduction Gain Energy [J]**

These are the power and energy sums for the Opaque Surface Outside Face Conduction values for all opaque surfaces in a zone when that sum is positive. For example, assume a zone has six opaque surfaces with Opaque Surface Outside Face Conduction values of 100, -200, 400, 50, 150 and -300 W. Then Zone Opaque Surface Outside Face Conduction Gain =  $700 - 500 = 200$  W.

#### **1.9.46.28 Zone Opaque Surface Outside Face Conduction Loss [W]**

#### **1.9.46.29 Zone Opaque Surface Outside Face Conduction Loss Energy [J]**

These are the power and energy absolute value for the sums of the Opaque Surface Outside Face Conduction values for all opaque surfaces in a zone when that sum is negative. For example, assume a zone has six opaque surfaces with Opaque Surface Outside Face Conduction values of -100, -200, 400, -50, 150 and -300W. Then Zone Opaque Surface Outside Face Conduction Loss =  $|550 - 650| = |-100| = 100$  W.

#### **1.9.46.30 Surface Inside Face Beam Solar Radiation Heat Gain Rate [W]**

Beam solar radiation from exterior windows absorbed on the inside face of an opaque heat transfer surface. For Solar Distribution = FullInteriorAndExterior, this quantity can be non-zero for both floor and wall surfaces. Otherwise, for Solar Distribution = FullExterior or MinimalShadowing, it can be non-zero only for floor surfaces since in this case all entering beam solar is assumed to fall on the floor. Note that this variable will not be operational (have a real value) unless there are exterior windows in the zone.

### **1.9.47 Window Output Variables**

The following output variables apply to subsurfaces that are windows or glass doors. These two subsurface types are called "window" here. "Exterior window" means that the base surface of the window is an exterior wall, floor, roof or ceiling (i.e., the base surface is a BuildingSurface:Detailed with OutsideFaceEnvironment = ExteriorEnvironment). "Interior window" means that the base surface of the window is an inter-zone wall, floor or ceiling. "Glass" means a transparent solid layer, usually glass, but possibly plastic or other transparent material. "Shading device" means an interior, exterior or between-glass shade or blind, or an exterior screen (only exterior windows can have a shading device).

#### **1.9.47.1 Zone Windows Total Transmitted Solar Radiation Rate [W]**

#### **1.9.47.2 Zone Windows Total Transmitted Solar Radiation Energy [J]**

The total Surface Window Transmitted Solar Radiation Rate of all the exterior windows in a zone.

#### **1.9.47.3 Zone Windows Total Heat Gain Rate [W]**

#### **1.9.47.4 Zone Windows Total Heat Gain Energy [J]**

The sum of the heat flow from all of the exterior windows in a zone when that sum is positive. (See definition of "heat flow" under "Window Heat Gain," below.)

#### **1.9.47.5 Zone Windows Total Heat Loss Rate [W]**

#### **1.9.47.6 Zone Windows Total Heat Loss Energy [J]**

The absolute value of the sum of the heat flow from all of the exterior windows in a zone when that sum is negative.

#### **1.9.47.7 Surface Window Total Glazing Layers Absorbed Shortwave Radiation Rate [W]**

**1.9.47.8 Surface Window Total Glazing Layers Absorbed Solar Radiation Rate [W]**

**1.9.47.9 Surface Window Total Glazing Layers Absorbed Solar Radiation Energy [J]**

The total exterior beam and diffuse solar radiation absorbed in all of the glass layers of an exterior window.

**1.9.47.10 Surface Window Shading Device Absorbed Solar Radiation Rate [W]**

Surface Window Shading Device Absorbed Solar Radiation Energy [J]

The exterior beam and diffuse solar radiation absorbed in the shading device, if present, of an exterior window.

**1.9.47.11 Surface Window Transmitted Solar Radiation Rate [W]**

**1.9.47.12 Surface Window Transmitted Solar Radiation Energy [J]**

The amount of beam and diffuse solar radiation entering a zone through an exterior window. It is the sum of the following two variables, "Surface Window Transmitted Beam Solar Radiation Rate" and "Surface Window Transmitted Diffuse Solar Radiation Rate."

**1.9.47.13 Surface Window Transmitted Beam Solar Radiation Rate [W]**

**1.9.47.14 Surface Window Transmitted Beam Solar Radiation Energy [J]**

The solar radiation transmitted by an exterior window whose source is beam solar incident on the outside of the window. For a bare window, this transmitted radiation consists of beam radiation passing through the glass (assumed transparent) and diffuse radiation from beam reflected from the outside window reveal, if present. For a window with a shade, this transmitted radiation is totally diffuse (shades are assumed to be perfect diffusers). For a window with a blind, this transmitted radiation consists of beam radiation that passes between the slats and diffuse radiation from beam-to-diffuse reflection from the slats. For a window with a screen, this value consists of direct beam radiation that is transmitted through the screen (gaps between the screen material) and diffuse radiation from beam-to-diffuse reflection from the screen material.

For each zone time step,

Surface Window Transmitted Beam Solar Radiation Rate = Surface Window Transmitted Beam To Beam Solar Radiation Rate + Surface Window Transmitted Beam To Diffuse Solar Radiation Rate

Surface Window Transmitted Beam Solar Radiation Energy = Surface Window Transmitted Beam To Beam Solar Radiation Energy + Surface Window Transmitted Beam To Diffuse Solar Radiation Energy

**1.9.47.15 Surface Window Transmitted Beam To Beam Solar Radiation Rate [W]**

**1.9.47.16 Surface Window Transmitted Beam To Beam Solar Radiation Energy [J]**

**1.9.47.17 For a window with a blind, this transmitted radiation consists of beam radiation that passes between the slats. For a window with a screen, this value consists of direct beam radiation that is transmitted through the screen (gaps between the screen material).**

**1.9.47.18 Surface Window Transmitted Beam To Diffuse Solar Radiation Rate [W]**

**1.9.47.19 Surface Window Transmitted Beam To Diffuse Solar Radiation Energy [J]**

**1.9.47.20 For a window with a blind, this transmitted radiation consists of diffuse radiation reflected from beam by the slats. For a window with a screen, this value consists of diffuse radiation reflected by the screen material.**

**1.9.47.21 Zone Exterior Windows Total Transmitted Beam Solar Radiation Rate [W]**

**1.9.47.22 Zone Exterior Windows Total Transmitted Beam Solar Radiation Energy [J]**

The sum of the Surface Window Transmitted Beam Solar Radiation Rate (see definition above) from all exterior windows in a zone.

**1.9.47.23 Zone Interior Windows Total Transmitted Beam Solar Radiation Rate [W]**

**1.9.47.24 Zone Interior Windows Total Transmitted Beam Solar Radiation Energy [J]**

The sum of the Surface Window Transmitted Beam Solar Radiation Rate (see definition above) from all interior windows in a zone.

**1.9.47.25 Surface Window Transmitted Diffuse Solar Radiation Rate [W]**

**1.9.47.26 Surface Window Transmitted Diffuse Solar Radiation Energy [J]**

The solar radiation transmitted by an exterior window whose source is diffuse solar incident on the outside of the window. For a bare window, this transmitted

radiation consists of diffuse radiation passing through the glass. For a window with a shade, this transmitted radiation is totally diffuse (shades are assumed to be perfect diffusers). For a window with a blind, this transmitted radiation consists of diffuse radiation that passes between the slats and diffuse radiation from diffuse-to-diffuse reflection from the slats. For a window with a screen, this value consists of diffuse radiation transmitted through the screen (gaps between the screen material) and diffuse radiation from diffuse-to-diffuse reflection from the screen material.

#### **1.9.47.27 Zone Exterior Windows Total Transmitted Diffuse Solar Radiation Rate [W]**

#### **1.9.47.28 Zone Exterior Windows Total Transmitted Diffuse Solar Radiation Energy [J]**

The combined beam and diffuse solar that first entered adjacent zones through exterior windows in the adjacent zones, was subsequently reflected from interior surfaces in those zones (becoming diffuse through that reflection), and was then transmitted through interior windows into the current zone.

#### **1.9.47.29 Zone Interior Windows Total Transmitted Diffuse Solar Radiation Rate [W]**

#### **1.9.47.30 Zone Interior Windows Total Transmitted Diffuse Solar Radiation Energy [J]**

The sum of the Surface Window Transmitted Diffuse Solar Radiation Rate (see definition above) from all interior windows in a zone.

#### **1.9.47.31 Surface Window System Solar Transmittance []**

Effective solar transmittance of an exterior window, including effect of shading device, if present. Equal to “Surface Window Transmitted Solar Radiation Rate” divided by total exterior beam plus diffuse solar radiation incident on the window (excluding frame, if present).

#### **1.9.47.32 Surface Window System Solar Absorptance []**

Effective solar absorptance of an exterior window, including effect of shading device, if present. Equal to “Window Solar Absorbed: All Glass Layers” plus “Window Solar Absorbed: Shading Device” divided by total exterior beam plus diffuse solar radiation incident on window (excluding frame, if present)

#### **1.9.47.33 Surface Window System Solar Reflectance []**

Effective solar reflectance of an exterior window, including effect of shading device, if present. Equal to:  $[1.0 - \text{“Surface Window System Solar Transmittance”} - \text{“Surface Window System Solar Absorptance”}]$ .

#### **1.9.47.34 Surface Window Gap Convective Heat Transfer Rate [W]**

#### **1.9.47.35 Surface Window Gap Convective Heat Transfer Energy [J]**

For an airflow window, the forced convective heat flow from the gap through which airflow occurs. This is the heat gained (or lost) by the air from the glass surfaces (and between-glass shading device surfaces, if present) that the air comes in contact with as it flows through the gap. If the gap airflow goes to the zone indoor air, the gap convective heat flow is added to the zone load. Applicable to exterior windows only.

#### **1.9.47.36 Surface Window Heat Gain Rate [W]**

#### **1.9.47.37 Surface Window Heat Gain Energy [J]**

The total heat flow to the zone from the glazing, frame and divider of an exterior window when the total heat flow is positive.

For a window *without an interior shading device*, this heat flow is equal to:

[Surface Window Transmitted Solar Radiation Rate (see definition, above)]

- [Convective heat flow to the zone from the zone side of the glazing]
- [Net IR heat flow to the zone from zone side of the glazing]

– [Short-wave radiation from zone transmitted back out the window]

- [Conduction to zone from window frame and divider, if present]

Here, short-wave radiation is that from lights and diffuse interior solar radiation.

For a window *with an interior shading device*, this heat flow is equal to:

[Surface Window Transmitted Solar Radiation Rate]

- [Convective heat flow to the zone from the air flowing through the gap between glazing and shading device]
- [Convective heat flow to the zone from the zone side of the shading device]
- [Net IR heat flow to the zone from the zone side of the glazing]

- [Net IR heat flow to the zone from the zone side of the shading device]

– [Short-wave radiation from zone transmitted back out the window]

- [Conduction to zone from window frame and divider, if present]

The total window heat flow can also be thought of as the sum of the solar and conductive gain from the window glazing.

#### **1.9.47.38 Surface Window Heat Loss Rate [W]**

#### **1.9.47.39 Surface Window Heat Loss Energy [J]**

The absolute value of the total heat flow through an exterior window when the total heat flow is negative. (See definition of “total heat flow” under “Surface Window Heat Gain Rate,” above.)

#### **1.9.47.40 Surface Window Glazing Beam to Beam Solar Transmittance []**

The fraction of exterior beam solar radiation incident on the glass of an exterior window that is transmitted through the glazing as beam radiation. This is for the base window without shading. Takes into account the angle of incidence of beam solar radiation on the glass.

#### **1.9.47.41 Surface Window Glazing Beam to Diffuse Solar Transmittance []**

The fraction of exterior beam solar radiation incident on the glazing of an exterior window that is transmitted through the glazing as diffuse radiation.

#### **1.9.47.42 Surface Window Glazing Diffuse to Diffuse Solar Transmittance []**

The fraction of exterior diffuse solar radiation incident on the glass of an exterior window that is transmitted through the glass assuming that the window has no shading device. It is assumed that incident diffuse solar is transmitted only as diffuse with no beam component.

#### **1.9.47.43 Surface Window Model Solver Iteration Count []**

The number of iterations needed by the window-layer heat balance solution to converge.

#### **1.9.47.44 Surface Window Solar Horizontal Profile Angle [deg]**

For a vertical exterior window, this is an angle appropriate for calculating beam solar quantities appropriate to horizontal window elements such as horizontal reveal surfaces, horizontal frame and divider elements and horizontal slats of window blinds. It is defined as the angle between the window outward normal and the projection of the sun’s ray on the vertical plane containing the outward normal. See Figure 32.

For an exterior window of arbitrary tilt, it is defined as the angle between the window outward normal the projection of the sun’s ray on the plane that contains the outward normal and is perpendicular to the ground.

If the sun is behind the window, the horizontal profile angle is not defined and is reported as 0.0.

Note that in most texts what we call “horizontal profile angle” is called “vertical profile angle.”

#### **1.9.47.45 Surface Window Solar Vertical Profile Angle [deg]**

For a vertical exterior window, this is an angle appropriate for calculating beam solar quantities appropriate to vertical window elements such as vertical reveal surfaces, vertical frame and divider elements and vertical slats of window blinds. It is defined as the angle between the window outward normal and the projection of the sun’s ray on the horizontal plane containing the outward normal. See **Figure 32**.

For an exterior window of arbitrary tilt, it is defined as the angle between the window outward normal the projection of the sun’s ray on the plane that contains the outward normal and is perpendicular to the plane defined above for Surface Window Solar Horizontal Profile Angle for a window of arbitrary tilt.

If the sun is behind the window, the vertical profile angle is not defined and is reported as 0.0.

Note that in most texts what we call “vertical profile angle” is called “horizontal profile angle.”

Figure 32. Vertical exterior window showing solar horizontal profile angle, solar vertical profile angle and solar incidence angle.

**1.9.47.46 Surface Window Outside Reveal Reflected Beam Solar Radiation Rate [W]**

**1.9.47.47 Surface Window Outside Reveal Reflected Beam Solar Radiation Energy [J]**

Beam solar radiation reflected from the outside reveal surfaces of a window (ref: Reveal Surfaces under WindowProperty:FrameAndDivider object). There are both rate and energy versions.

**1.9.47.48 Surface Window Inside Reveal Reflected Beam Solar Radiation Rate [W]**

**1.9.47.49 Surface Window Inside Reveal Reflected Beam Solar Radiation Energy [J]**

Beam solar radiation reflected from the inside reveal surfaces of a window (ref: Reveal Surfaces under WindowProperty:FrameAndDivider object). There are both rate and energy versions.

**1.9.47.50 Surface Window Inside Reveal Absorbed Beam Solar Radiation Rate [W]**

Beam solar radiation absorbed at the inside reveal surfaces of a window, in Watts.

**1.9.47.51 Surface Window Inside Reveal Reflected Diffuse Zone Solar Radiation Rate [W]**

Diffuse solar radiation reflected from inside reveal surfaces of a window into the zone, in Watts.

**1.9.47.52 Surface Window Inside Reveal Reflected Diffuse Frame Solar Radiation Rate [W]**

Diffuse solar radiation reflected from inside reveal surfaces onto the frame surfaces of a window, in Watts.

**1.9.47.53 Surface Window Inside Reveal Reflected Diffuse Glazing Solar Radiation Rate [W]**

Diffuse solar radiation reflected from inside reveal surfaces onto the glazing surfaces of a window, in Watts.

**1.9.47.54 Surface Window Inside Face Glazing Condensation Status []**

A value of 1 means that moisture condensation will occur on the innermost glass face of an exterior window (i.e., on the glass face in contact with the zone air). Otherwise the value is 0. The condition for condensation is glass inside face temperature < zone air dewpoint temperature.

For airflow exterior windows, in which forced air passes between adjacent glass faces in double- and triple-pane windows, a value of 1 means that condensation will occur on one or both of the glass faces in contact with the airflow. In this case the condition for condensation is:

- For *airflow source = indoorair*, temperature of either face in contact with airflow < zone air dewpoint temperature.
- For *airflow source = outdoorair*, temperature of either face in contact with airflow < outside air dewpoint temperature.

As for regular windows, the value will also be 1 if condensation occurs on the innermost glass face.

**1.9.47.55 Surface Window Inside Face Frame Condensation Status []**

If an exterior window has a frame and the value of this flag is 1, condensation will occur on the inside surface of the frame. The condition for condensation is frame inside surface temperature < zone air dewpoint temperature.

**1.9.47.56 Surface Window Inside Face Divider Condensation Status []**

If an exterior window has a divider and the value of this flag is 1, condensation will occur on the inside surface of the divider. The condition for condensation is divider inside surface temperature < zone air dewpoint temperature.

#### **1.9.47.57 Surface Shading Device Is On Time Fraction []**

The fraction of time that a shading device is on an exterior window. For a particular simulation timestep, the value is 0.0 if the shading device is off (or there is no shading device) and the value is 1.0 if the shading device is on. (It is assumed that the shading device, if present, is either on or off for the entire timestep.) If the shading device is switchable glazing, a value of 0.0 means that the glazing is in the unswitched (light colored) state, and a value of 1.0 means that the glazing is in the switched (dark colored) state.

For a time interval longer a timestep, this is the fraction of the time interval that the shading device is on. For example, take the case where the time interval is one hour and the timestep is 10 minutes. Then if the shading device is on for two timesteps in the hour and off for the other four timesteps, then the fraction of time that the shading device is on =  $2/6 = 0.3333$ .

#### **1.9.47.58 Surface Window Blind Slat Angle [deg]**

For an exterior window with a blind, this is the angle in degrees between the glazing outward normal and the blind slat angle outward normal, where the outward normal points away from the front face of the slat. The slat angle varies from 0 to 180 deg. If the slat angle is 0 deg or 180 deg, the slats are parallel to the glazing and the slats are said to be “closed”. If the slat angle is 90 deg, the slats are perpendicular to the glazing and the slats are said to be “fully open”. See illustrations under WindowMaterial:Blind. For blinds with a fixed slat angle, the value reported here will be constant.

#### **1.9.47.59 Surface Window Blind Beam to Beam Solar Transmittance []**

For an exterior window with a blind, this is the fraction of exterior beam solar radiation incident on the blind that is transmitted through the blind as beam solar radiation when the blind is isolated (i.e., as though the window glass were not present). Depends on various factors, including slat angle, width, separation, and thickness, and horizontal solar profile angle (for blinds with horizontal slats) or vertical solar profile angle (for blinds with vertical slats). The transmittance value reported here will be non-zero only when some beam solar can pass through the blind without hitting the slats.

#### **1.9.47.60 Surface Window Blind Beam to Diffuse Solar Transmittance []**

For an exterior window with a blind, the fraction of exterior beam solar radiation incident on the blind that is transmitted through the blind as diffuse solar radiation when the blind is isolated (i.e., as though the window glass were not present). Depends on various factors, including slat angle, width, separation, thickness and reflectance, and horizontal solar profile angle (for blinds with horizontal slats) or vertical solar profile angle (for blinds with vertical slats).

#### **1.9.47.61 Surface Window Blind Diffuse to Diffuse Solar Transmittance []**

For an exterior window with a blind, the fraction of exterior diffuse solar radiation incident on the blind that is transmitted through the blind as diffuse solar radiation when the blind is isolated (i.e., as though the window glass were not present). Depends on various factors, including slat angle, width, separation, thickness and reflectance. For blinds with a fixed slat angle the transmittance value reported here will be constant.

#### **1.9.47.62 Surface Window Blind and Glazing System Beam Solar Transmittance []**

The fraction of exterior beam solar radiation incident on an exterior window with a blind (excluding window frame, if present) that is transmitted through the blind/glass system as beam solar radiation. Depends on various factors, including type of glass; solar incidence angle; slat angle, width, separation, and thickness; and horizontal solar profile angle (for blinds with horizontal slats) or vertical solar profile angle (for blinds with vertical slats).

#### **1.9.47.63 Surface Window Blind and Glazing System Diffuse Solar Transmittance []**

The fraction of exterior diffuse solar radiation incident on an exterior window with a blind (excluding window frame, if present) that is transmitted through the blind/glass system as diffuse solar radiation. Depends on various factors, including type of glass and slat angle, width, separation, thickness and reflectance. For blinds with a fixed slat angle the transmittance value reported here will be constant.

#### **1.9.47.64 Surface Window Screen Beam to Beam Solar Transmittance []**

For an exterior window with a screen, this is the fraction of exterior beam solar radiation incident on the screen that is transmitted through the screen as beam solar radiation when the screen is isolated (i.e., as though the window glass were not present). Depends on various factors, including the screen reflectance and the relative angle of the incident beam with respect to the screen. This value will include the amount of inward reflection of solar beam off the screen material surface if the user specifies this modeling option (i.e., Material: WindowScreen, field Reflected Beam Transmittance Accounting Method = Model as Direct Beam).

#### **1.9.47.65 Surface Window Screen Beam to Diffuse Solar Transmittance[]**

For an exterior window with a screen, the fraction of exterior beam solar radiation incident on the screen that is transmitted through the screen as diffuse solar radiation when the screen is isolated (i.e., as though the window glass were not present). Depends on various factors, including the screen reflectance and the relative angle of the incident beam with respect to the screen. This value is the amount of inward reflection of solar beam off the screen material surface if the user specifies this modeling option (i.e., Material: WindowScreen, field Reflected Beam Transmittance Accounting Method = Model as Diffuse); otherwise, this value will be zero.

#### **1.9.47.66 Surface Window Screen Diffuse to Diffuse Solar Transmittance[]**

For an exterior window with a screen, the fraction of exterior diffuse solar radiation incident on the screen that is transmitted through the screen as diffuse solar radiation when the screen is isolated (i.e., as though the window glass were not present). Depends on various factors including screen material geometry and reflectance. This value is calculated as an average, constant For a window with a screen, this value consists of diffuse radiation transmitted through the screen (gaps between the screen material) and diffuse radiation from diffuse-to-diffuse reflection from the screen material. For a window with a screen, this value consists of diffuse radiation transmitted through the screen (gaps between the screen material) and diffuse radiation from diffuse-to-diffuse reflection from the screen material.

#### **1.9.47.67 Surface Window Screen and Glazing System Beam Solar Transmittance[]**

The fraction of exterior beam solar radiation incident on an exterior window with a screen (excluding window frame, if present) that is transmitted through the screen/glass system as beam solar radiation. Depends on various factors, including the screen reflectance and the relative angle of the incident beam with respect to the screen. This value will include the amount of inward reflection of solar beam off the screen material surface if the user specifies this modeling option (i.e., Material: WindowScreen, field Reflected Beam Transmittance Accounting Method = Model as Direct Beam).

#### **1.9.47.68 Surface Window Screen and Glazing System Diffuse Solar Transmittance []**

The fraction of exterior diffuse solar radiation incident on an exterior window with a screen (excluding window frame, if present) that is transmitted through the screen/glass system as diffuse solar radiation. Depends on various factors including screen material geometry and reflectance.

#### **1.9.47.69 Surface Window Transmitted Beam Solar Radiation Rate [W]**

#### **1.9.47.70 Surface Window Transmitted Beam Solar Radiation Energy [J]**

The beam solar radiation transmitted through an interior window. Calculated only if Solar Distribution = FullInteriorAndExterior in your Building input. The origin of this radiation is beam solar that enters through an exterior window in a zone and then passes through an interior window into the adjacent zone. The amount of this radiation depends on several factors, including sun position, intensity of beam solar incident on the exterior window (including effects of shadowing, if present), relative position of the exterior and interior window, and the size and transmittance of the windows. Note that if there are two or more exterior windows in a zone, then beam solar from one or more of them may pass through the same interior window. Likewise, if there are more than two or more interior windows in a zone then beam solar from a single exterior window may pass through one or more of the interior windows. There are both rate and energy versions of the output.

#### **1.9.47.71 Surface Storm Window On Off Status [ ]**

Indicates whether a storm window glass layer is present (ref: StormWindow object). The value is **0** if the storm window glass layer is off, **1** if it is on, and **-1** if the window does not have an associated storm window. Applicable only to exterior windows and glass doors.

#### **1.9.47.72 Surface Inside Face Initial Transmitted Diffuse Transmitted Out Window Solar Radiation Rate [W]**

As of Version 2.1, the diffuse solar transmitted through exterior windows that is initially distributed to another window in the zone and transmitted out of the zone through that window. For exterior windows, this transmitted diffuse solar is "lost" to the exterior environment For interior windows, this transmitted diffuse solar is distributed to heat transfer surfaces in the adjacent zone, and is part of the Surface Inside Face Initial Transmitted Diffuse Absorbed Solar Radiation Rate for these adjacent zone surfaces.

#### **1.9.47.73 Additional Window Outputs (Advanced)**

The following output variables for windows or glass doors are available when the user requests to display advanced output variables. These seven reports show the individual components that are combined to determine overall Surface Window Heat Gain Rate and/or Surface Window Heat Loss Rate (described above).

#### **1.9.47.74 Surface Window Inside Face Glazing Zone Convection Heat Gain Rate [W]**

The surface convection heat transfer from the glazing to the zone in watts. This output variable is the term called "[Convective heat flow to the zone from the zone side of the glazing]" under the description above for Surface Window Heat Gain Rate output variable. If the window has an interior shade or blind, then this is zero and the glazing's convection is included in the report called "Surface Window Inside Face Gap between Shade and Glazing Zone Convection Heat Gain Rate".

#### **1.9.47.75 Surface Window Inside Face Glazing Net Infrared Heat Transfer Rate [W]**

The net exchange of infrared radiation heat transfer from the glazing to the zone in watts. This output variable is the term called "[Net IR heat flow to the zone from zone side of the glazing]" under the description above for Surface Window Heat Gain Rate output variable.

#### **1.9.47.76 Surface Window Shortwave from Zone Back Out Window Heat Transfer Rate [W]**

This is the short-wave radiation heat transfer from the zone back out the window in watts. This is a measure of the diffuse short-wave light (from reflected solar and electric lighting) that leave the zone through the window. This output variable is the term called "[Short-wave radiation from zone transmitted back out the window]" under the description above for Surface Window Heat Gain Rate output variable.

#### **1.9.47.77 Surface Window Inside Face Frame and Divider Zone Heat Gain Rate [W]**

This is the heat transfer from any frames and/or dividers to the zone in watts. This output variable is the term called “[Conduction to zone from window frame and divider, if present]” under the description above for Surface Window Heat Gain Rate output variable. (The word “conduction” here is used because the models is simplified compared to the complexities of surface convection and radiation.)

#### **1.9.47.78 Surface Window Frame Heat Gain Rate [W]**

This is the positive heat flow from window frames to the zone in watts. This is part of the Surface Window Inside Face Frame and Divider Zone Heat Gain Rate.

#### **1.9.47.79 Surface Window Frame Heat Loss Rate [W]**

This is the negative heat flow from window frames to the zone in watts. This is part of the Surface Window Inside Face Frame and Divider Zone Heat Gain Rate.

#### **1.9.47.80 Surface Window Frame Inside Temperature [C]**

This is the temperature of the inside surface of the window frames.

#### **1.9.47.81 Surface Window Frame Outside Temperature [C]**

This is the temperature of the outside surface of the window frames.

#### **1.9.47.82 Surface Window Divider Heat Gain Rate [W]**

This is the positive heat flow from window dividers to the zone in watts. This is part of the Surface Window Inside Face Frame and Divider Zone Heat Gain Rate.

#### **1.9.47.83 Surface Window Divider Heat Loss Rate [W]**

This is the negative heat flow from window dividers to the zone in watts. This is part of the Surface Window Inside Face Frame and Divider Zone Heat Gain Rate.

#### **1.9.47.84 Surface Window Divider Inside Temperature [C]**

This is the temperature of the inside surface of the window dividers.

#### **1.9.47.85 Surface Window Divider Outside Temperature [C]**

This is the temperature of the outside surface of the window dividers.

#### **1.9.47.86 Surface Window Inside Face Gap between Shade and Glazing Zone Convection Heat Gain Rate [W]**

This is the convection surface heat transfer from the both the glazing and the shade’s back face to the zone in Watts. This output variable is the term called “[Convective heat flow to the zone from the air flowing through the gap between glazing and shading device]” under the description above for Surface Window Heat Gain Rate output variable. For Equivalent Layer window this output variable is the convection heat gain from vented interior air gap to the zone in Watts.

#### **1.9.47.87 Surface Window Inside Face Shade Zone Convection Heat Gain Rate [W]**

This is the convection surface heat transfer from the front side of any interior shade or blind to the zone in Watts. This output variable is the term called “[Convective heat flow to the zone from the zone side of the shading device]” under the description above for Surface Window Heat Gain Rate output variable. For equivalent Layer window this output variable is the convection heat gain rate from the inside face of a glazing or a shade to the zone in Watts.

#### **1.9.47.88 Surface Window Inside Face Shade Net Infrared Heat Transfer Rate [W]**

The net exchange of infrared radiation heat transfer from the shade or blind to the zone in watts. This output variable is the term called “[Net IR heat flow to the zone from the zone side of the shading device]” under the description above for Surface Window Heat Gain Rate output variable.

#### ***Surface Window Inside Face Other Convection Heat Gain Rate [W]***

The other (extra) convection heat transfer rate from the inside face of a an equivalent layer window. This output is computed from the difference in convection flux when using equivalent inside surface temperature of a window instead of the inside surface temperature from the standard surface heat balance calculation.

### **1.9.48 Thermochromic Window Outputs**

#### **1.9.48.1 Window Thermochromic Layer Temperature [C]**

The temperature of the TC glass layer of a TC window at each time step.

#### **1.9.48.2 Surface Window Thermochromic Layer Property Specification Temperature [C]**

The temperature under which the optical data of the TC glass layer are specified.

The overall properties (U-factor/SHGC/VT) of the thermochromic windows at different specification temperatures are reported in the **eio** file. These window constructions are created by EnergyPlus during run time. They have similar names with suffix “\_TC\_XX” where XX represents a specification temperature.

### 1.9.48.3 Switchable Window Outputs

#### 1.9.48.4 Surface Window Switchable Glazing Switching Factor[]

The switching factor (tint level) of the switchable window: 0 means no switching – clear state; 1 means fully switched – dark state.

#### 1.9.48.5 Surface Window Switchable Glazing Visible Transmittance[]

The visible transmittance of the switchable window.

### 1.9.49 Other Surface Outputs/Reports

Several reports can be selected for Surfaces. (See Group – Report for details on how to specify). Examples are:

#### 1.9.49.1 DXF

This report produces a special file (**eplusout.dxf**) in the industry standard DXF (Drawing Interchange Format) for drawings. It is produced and accepted by many popular, commercial CAD programs. Detailed reference can be found on the AutoCAD™ website at:

<http://www.autodesk.com/techpubs/autocad/acadr14/dxf/index.htm>

EnergyPlus produces this file from the Report command:

Output:Reports, Surfaces, DXF;

#### 1.9.49.2 Details, Vertices, DetailsWithVertices

This version of the report creates lines in the eplusout.eio file for each surface (except internal mass surfaces). Details of this reporting is shown in the Output Details and Examples document.

### 1.9.50 Shading Surfaces

Shading surfaces are entities outside of the building that may cast shadows on the building's heat transfer surfaces. These entities do not typically have enough thermal mass to be described as part of the building's thermal makeup.

The most important effect of shading surfaces is to reduce solar gain in windows that are shadowed. (However, in some cases, shading surfaces can reflect solar onto a wall or window and increase solar gain.)

There are two kinds of shading surfaces in EnergyPlus: **detached** and **attached**. A **detached** shading surface, such as a tree or neighboring building, is not connected to the building. An **attached** shading surface is typically an overhang or fin that is attached to a particular base surface of the building, usually a wall; attached shading surfaces are usually designed to shade specific windows.

Objects for detached shading surfaces:

- Shading:Site
- Shading:Building
- Shading:Site:Detailed
- Shading:Building:Detailed

Similarly to the surfaces, the detailed objects use vertex entry whereas the other objects are limited to rectangular representation.

Objects for attached shading surfaces:

- Shading:Overhang
- Shading:Overhang:Projection
- Shading:Fin
- Shading:Fin:Projection
- Shading:Zone:Detailed

EnergyPlus creates “bi-directional” shades from each shading surface entered. This means that the shade you input will cast a shadow no matter which side of the shade the sun is on. For example, a vertical fin will cast a shadow whether the sun is on the left side or right side of the fin. Prior to V1.0.2, a shading surface

cast a shadow only in the hemisphere toward which the surface faced. This hemisphere is the one pointed to by the shading surface's outward normal vector, which is the cross product  $V_{23} \times V_{21}$ , where  $V_{23}$  is the vector from vertex 2 to vertex 3 of the shading surface and  $V_{21}$  is the vector from vertex 2 to vertex 1. Beginning with V1.0.2, the shades in EnergyPlus are "bi-directional" so that they can cast shadows in both hemispheres depending on the time-varying position of the sun relative to the shading surface.

It is important to note that EnergyPlus will automatically account for "self-shading" effects—such as in L-shaped buildings—in which some of the building's wall and roof surfaces shade other parts of the building, especially windows. This means that you only need to describe shading elements that aren't building heat-transfer surfaces.

Shading surfaces can also **reflect** solar radiation onto the building. This feature is simulated if you choose FullExteriorWithReflections or FullInteriorAndExteriorWithReflections in the Building object (ref: Building - Field: Solar Distribution). In this case, you may specify the reflectance properties of a shading surface with the ShadingProperty:Reflectance object. Note: If no ShadingProperty:Reflectance object is defined, then the shading surface reflectance values are assumed to be 0.2 and the fraction of shading surface that is glazed is assumed to be 0.0.

Shading surfaces also automatically shade diffuse solar radiation (and long-wave radiation) from the sky. And they will automatically shade diffuse solar radiation from the ground if Solar Distribution Field = FullExteriorWithReflections or FullInteriorAndExteriorWithReflections in the Building object. (If the reflections option for Solar Distribution is used, the program also takes into account the reduction of solar radiation reflected from the ground due to shading of the ground by shading surfaces and by the building itself.) Otherwise, shading surfaces will not shade diffuse radiation from the ground unless you enter a reduced value for View Factor to Ground for those building surfaces that are shaded (ref: BuildingSurface:Detailed - Field: View Factor to Ground and FenestrationSurface:Detailed - Field: View Factor to Ground).

### 1.9.51 Detached Shading Surfaces

#### 1.9.52 Shading:Site, Shading:Building

These objects are used to describe rectangular shading elements that are external to the building. Examples are trees, high fences, near-by hills, and neighboring buildings.

If relative coordinates are used (ref: Field: Coordinate System in GlobalGeometryRules), shading surfaces entered with Shading:Site remain stationary if the building is rotated, whereas those entered with Shading:Building rotate with the building. If world coordinates are used Shading:Site and Shading:Building are equivalent.

These shading elements are always opaque.

##### 1.9.52.1 Field: Name

This is a unique character string associated with the detached shading surface. Though it must be unique from other surface names, it is used primarily for convenience with detached shading surfaces.

##### 1.9.52.2 Field: Azimuth Angle

Theoretically, this should face to the surface it is shading (i.e. if a south wall, this should be a north facing shade) but since EnergyPlus automatically generates the mirror image, the facing angle per se' is not so important.

##### 1.9.52.3 Field: Tilt Angle

The tilt angle is the angle (in degrees) that the shade is tilted from horizontal (or the ground). Default for this field is 90 degrees.

##### 1.9.52.4 Starting Corner for the surface

The rectangular surfaces specify the lower left corner of the surface for their starting coordinate. See the introductory paragraph for rules on this entry.

##### 1.9.52.5 Field: Starting X Coordinate

This field is the X coordinate (in meters).

##### 1.9.52.6 Field: Starting Y Coordinate

This field is the Y coordinate (in meters).

##### 1.9.52.7 Field: Starting Z Coordinate

This field is the Z coordinate (in meters).

##### 1.9.52.8 Field: Length

This field is the length of the shade in meters.

### 1.9.52.9 Field: Height

This field is the width of the shade in meters.

Examples of these (can be found in example files 4ZoneWithShading\_Simple\_1.idf and 4ZoneWithShading\_Simple\_2.idf)

```
Shading:Building,
  Bushes-East,           !- Name
  90,                   !- Azimuth Angle {deg}
  90,                   !- Tilt Angle {deg}
  45,                   !- Starting X Coordinate {m}
  0,                    !- Starting Y Coordinate {m}
  0,                    !- Starting Z Coordinate {m}
  50,                   !- Length {m}
  1;                    !- Height {m}
```

```
Shading:Site,
  Bushes-North,        !- Name
  0,                   !- Azimuth Angle {deg}
  90,                   !- Tilt Angle {deg}
  45,                   !- Starting X Coordinate {m}
  50,                   !- Starting Y Coordinate {m}
  0,                    !- Starting Z Coordinate {m}
  50,                   !- Length {m}
  1;                    !- Height {m}
```

### 1.9.53 Shading:Site:Detailed, Shading:Building:Detailed

These objects are used to describe shading elements that are external to the building. Examples are trees, high fences, near-by hills, and neighboring buildings.

If relative coordinates are used (ref: Field: Coordinate System in GlobalGeometryRules), shading surfaces entered with Shading:Site:Detailed remain stationary if the building is rotated, whereas those entered with Shading:Building:Detailed rotate with the building. If world coordinates are used Shading:Site:Detailed and Shading:Building:Detailed are equivalent.

While "detached" implies that shading surfaces are not part of the building, the detached shading sequence can be used to describe attached shading surfaces that may shade heat transfer surfaces in more than one zone. For example, wing A of a building might shade several zones of wing B but wing A (for whatever reason) is not described in the geometry for the simulation so it is represented by a detached shade to get its shadowing effect.

#### 1.9.53.1 Field: Name

This is a unique character string associated with the detached shading surface. Though it must be unique from other surface names, it is used primarily for convenience with detached shading surfaces.

#### 1.9.53.2 Field: Transmittance Schedule Name

The name of a schedule of solar transmittance values from 0.0 to 1.0 for the shading surface. If a blank is entered in this field, the transmittance value defaults to 0.0, i.e., the shading surface is opaque at all times. This scheduling can be used to allow for seasonal transmittance change, such as for deciduous trees that have a higher transmittance in winter than in summer. Transmittance based on time of day can also be used—a movable awning, for example, where the transmittance is some value less than 1.0 when the awning is in place and is 1.0 when the awning is retracted.

The following assumptions are made in the shading surface transmittance calculation:

- Both sides of the shading surface have the same transmittance properties.
- The transmittance is the same for both beam and diffuse solar radiation.
- Beam solar transmittance is independent of angle of incidence on the shading surface.
- Beam radiation incident on a shading surface is transmitted as beam radiation with no change in direction, i.e., there is no beam-to-diffuse component.
- If two shading surfaces with non-zero transmittance overlap, the net transmittance is the product of the individual transmittances. Inter-reflection between the shading surfaces (and between the shading surfaces and the building) is ignored.
- For the daylighting calculation (ref: Group – Daylighting) the shading surface's visible transmittance is assumed to be the same as its solar transmittance.
- Shading devices are assumed to be opaque to long-wave radiation no matter what the solar transmittance value is.

Note that shading devices only shade solar radiation when the sun is up, which is automatically determined by EnergyPlus from latitude, time of year, etc. The user need only account for the time-varying transmittance of the shading device in the transmittance schedule, not whether the sun is up or not.

#### 1.9.53.3 Field: Number Vertices

The number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on "Surface Vertices" above.

IDF example of Detached Shading Surfaces:

```
Shading:Building:Detailed,  
  EAST SIDE TREE, !- Detached Shading  
  ShadingTransmittance:0002, !- Shadowing Transmittance & Schedule  
  3, !-Triangle  
  33.52800 , 10.66800 , 10.05800 ,  
  33.52800 , 13.71600 , 0.9140000 ,  
  33.52800 , 4.572000 , 0.9140000 ;
```

```
Shading:Building:Detailed,  
  WEST SIDE TREE, !- Detached Shading  
  ShadingTransmittance:0002, !- Shadowing Transmittance & Schedule  
  3, !-Triangle  
  -3.048000 , 7.620000 , 10.05800 ,  
  -3.048000 , 4.572000 , 0.9140000 ,  
  -3.048000 , 13.71600 , 0.9140000 ;
```

### 1.9.54 Attached Shading Surfaces

Overhangs are usually horizontal devices that are used to shade windows. Fins are usually vertical devices that similarly shade windows.

### 1.9.55 Shading:Overhang

An overhang typically is used to shade a window in a building.

#### 1.9.55.1 Field: Name

This is the name of the overhang. It must be different from other surface names.

#### 1.9.55.2 Field: Window or Door Name

The name of a window or door that this overhang shades.

#### 1.9.55.3 Field: Height above Window or Door

This field is the height (meters) above the top of the door for the overhang.

#### 1.9.55.4 Field Tilt Angle from Window/Door

This field is the tilt angle from the Window/Door. For a flat overhang, this would be 90 (degrees).

#### 1.9.55.5 Field: Left Extension from Window/Door Width

This field is the width from the left edge of the window/door to the start of the overhang (meters).

#### 1.9.55.6 Field: Right Extension from Window/Door Width

This field is the width from the right edge of the window/door to the start of the overhang (meters).

#### 1.9.55.7 Field: Depth

This field is the depth of the overhang (meters) projecting out from the wall.

### 1.9.56 Shading:Overhang:Projection

An overhang typically is used to shade a window in a building. This object allows for specifying the depth of the overhang as a fraction of the window or door's height.

#### 1.9.56.1 Field: Name

This is the name of the overhang. It must be different from other surface names.

#### 1.9.56.2 Field: Window or Door Name

The name of a window or door that this overhang shades.

#### 1.9.56.3 Field: Height above Window or Door

This field is the height (meters) above the top of the door for the overhang.

#### **1.9.56.4 Field Tilt Angle from Window/Door**

This field is the tilt angle from the Window/Door. For a flat overhang, this would be 90 (degrees).

#### **1.9.56.5 Field: Left Extension from Window/Door Width**

This field is the width from the left edge of the window/door to the start of the overhang (meters).

#### **1.9.56.6 Field: Right Extension from Window/Door Width**

This field is the width from the right edge of the window/door to the start of the overhang (meters).

#### **1.9.56.7 Field: Depth as Fraction of Window/Door Height**

This field is the fraction of the window/door height to specify as the depth of the overhang (meters) projecting out from the wall.

### **1.9.57 Shading:Fin**

Fins shade either side of windows/doors in a building. This object allows for specification of both fins for the window. Fin placement is relative to the edge of the glass and user must include the frame width when a frame is present.

#### **1.9.57.1 Field: Name**

This is the name of the overhang. It must be different from other surface names.

#### **1.9.57.2 Field: Window or Door Name**

The name of a window or door that this overhang shades.

#### **1.9.57.3 Field: Left Fin Extension from Window/Door**

This field is the width from the left edge of the window/door to the plane of the left fin (meters). The extension width is relative to the edge of the glass and includes the frame width when a frame is present.

#### **1.9.57.4 Field: Left Fin Distance Above Top of Window**

This field is the distance from the top of the window to the top of the left fin (meters) and is relative to the edge of the glass and includes the frame width when a frame is present.

#### **1.9.57.5 Field: Left Fin Distance Below Bottom of Window**

This field is the distance from the bottom of the window to the bottom of the left fin (meters) and is relative to the edge of the glass and includes the frame width when a frame is present.

#### **1.9.57.6 Field: Left Fin Tilt Angle from Window/Door**

This field is the tilt angle from the window / door for the left fin. Typically, a fin is 90 degrees (default) from its associated window/door.

#### **1.9.57.7 Field: Left Fin Depth**

This field is the depth (meters) of the left fin (projecting out from the wall).

#### **1.9.57.8 Field: Right Fin Extension from Window/Door**

This field is the width from the right edge of the window/door to the plane of the right fin (meters). The extension width is relative to the edge of the glass and includes the frame width when a frame is present.

#### **1.9.57.9 Field: Right Fin Distance Above Top of Window**

This field is the distance from the top of the window to the top of the right fin (meters) and is relative to the edge of the glass and includes the frame width when a frame is present.

#### **1.9.57.10 Field: Right Fin Distance Below Bottom of Window**

This field is the distance from the bottom of the window to the bottom of the right fin (meters) and is relative to the edge of the glass and includes the frame width.

#### **1.9.57.11 Field: Right Fin Tilt Angle from Window/Door**

This field is the tilt angle from the window / door for the right fin.. Typically, a fin is 90 degrees (default) from its associated window/door.

#### **1.9.57.12 Field: Right Fin Depth**

This field is the depth (meters) of the right fin (projecting out from the wall).

### **1.9.58 Shading:Fin:Projection**

Fins shade either side of windows/doors in a building. This object allows for specification of both fins for the window. This object allows for specifying the depth of the overhang as a fraction of the window or door's width. Fin placement is relative to the edge of the glass and user must include the frame width when a frame is present.

#### **1.9.58.1 Field: Name**

This is the name of the overhang. It must be different from other surface names.

#### **1.9.58.2 Field: Window or Door Name**

The name of a window or door that this overhang shades.

#### **1.9.58.3 Field: Left Fin Extension from Window/Door**

This field is the width from the left edge of the window/door to the plane of the left fin (meters). The extension width is relative to the edge of the glass and includes the frame width when a frame is present.

#### **1.9.58.4 Field: Left Fin Distance Above Top of Window**

This field is the distance from the top of the window to the top of the left fin (meters) and is relative to the edge of the glass and includes the frame width when a frame is present.

#### **1.9.58.5 Field: Left Fin Distance Below Bottom of Window**

This field is the distance from the bottom of the window to the bottom of the left fin (meters) and is relative to the edge of the glass and includes the frame width when a frame is present.

#### **1.9.58.6 Field: Left Fin Tilt Angle from Window/Door**

This field is the tilt angle from the window / door for the left fin. Typically, a fin is 90 degrees (default) from its associated window/door.

#### **1.9.58.7 Field: Left Fin Depth as Fraction of Window/Door Width**

This field is the fraction of the window/door width to specify as the depth of the left fin (meters) projecting out from the wall.

#### **1.9.58.8 Field: Right Fin Extension from Window/Door**

This field is the width from the right edge of the window/door to the plane of the right fin (meters).. The extension width is relative to the edge of the glass and includes the frame width when a frame is present.

#### **1.9.58.9 Field: Right Fin Distance Above Top of Window**

This field is the distance from the top of the window to the top of the right fin (meters) and is relative to the edge of the glass and includes the frame width when a frame is present.

#### **1.9.58.10 Field: Right Fin Distance Below Bottom of Window**

This field is the distance from the bottom of the window to the bottom of the right fin (meters) and is relative to the edge of the glass and includes the frame width when a frame is present.

#### **1.9.58.11 Field: Right Fin Tilt Angle from Window/Door**

This field is the tilt angle from the window / door for the right fin.. Typically, a fin is 90 degrees (default) from its associated window/door.

#### **1.9.58.12 Field: Right Fin Depth as Fraction of Window/Door Width**

This field is the fraction of the window/door width to specify as the depth of the right fin (meters) projecting out from the wall.

zone.

Examples of these (can be found in example files 4ZoneWithShading\_Simple\_1.idf and 4ZoneWithShading\_Simple\_2.idf)

### 1.9.59 Shading:Zone:Detailed

This object is used to describe attached “subsurfaces” such as overhangs, wings or fins that project outward from a base surface. This classification is used for convenience; actually, a device of this type can cast shadows on the surface to which it is attached as well as on adjacent surfaces. For example, a fin may shade its parent wall as well as adjacent walls.

Note that a zone surface can cast shadows on other zone surfaces. However, you don’t have to worry about such effects—for example, one wall of an L-shaped building shading another wall—because EnergyPlus will automatically check for this kind of “self shadowing” and do the proper calculations.

Unlike attached (or detached) shading surfaces, building surfaces can only cast shadows in the hemisphere towards which they face. This means, for example, that a roof that faces *upward* will not cast a shadow *downward*. (Thus, specifying an oversized roof in an attempt to account for the shading effects of overhangs will *not* work). Interior surfaces do not cast shadows of any kind.

#### 1.9.59.1 Field: Name

This is the name of the attached shading surface. It must be different from other surface names.

#### 1.9.59.2 Field: Base Surface Name

This is the name of the surface to which this shading device is attached. This surface can be a wall (or roof) but not a window or door.

#### 1.9.59.3 Field: Transmittance Schedule Name

The name of a schedule of solar transmittance values from 0.0 to 1.0 for the shading surface. If a blank is entered in this field, the transmittance value defaults to 0.0, i.e., the shading surface is opaque at all times. This scheduling can be used to allow for seasonal transmittance change, such as for deciduous trees that have a higher transmittance in winter than in summer. Transmittance based on time of day can also be used—a movable awning, for example, where the transmittance is some value less than 1.0 when the awning is in place and is 1.0 when the awning is retracted.

The following assumptions are made in the shading surface transmittance calculation:

- Both sides of the shading surface have the same transmittance properties.
- The transmittance is the same for both beam and diffuse solar radiation.
- Beam solar transmittance is independent of angle of incidence on the shading surface.
- Beam radiation incident on a shading surface is transmitted as beam radiation with no change in direction, i.e., there is no beam-to-diffuse component.
- If two shading surfaces with non-zero transmittance overlap, the net transmittance is the product of the individual transmittances. Inter-reflection between the shading surfaces (and between the shading surfaces and the building) is ignored.

- For the daylighting calculation (ref: Group – Daylighting) the shading surface's visible transmittance is assumed to be the same as its solar transmittance.
- Shading devices are assumed to be opaque to long-wave radiation no matter what the solar transmittance value is.

Note that shading devices only shade solar radiation when the sun is up, which is automatically determined by EnergyPlus from latitude, time of year, etc. The user need only account for the time-varying transmittance of the shading device in the transmittance schedule, not whether the sun is up or not.

#### 1.9.59.4 Field: Number Vertices

The number of sides in the surface (number of X,Y,Z vertex groups). For further information, see the discussion on "Surface Vertices" above. The example below shows the correct input for an overhang (to shade the appropriate portion of the base wall and window).

Figure 33. Illustration for Attached Shading Surface

Proper specification for this overhang (facing up) is:

4,(C,0,D),(C,-B,D),(C+A,-B,D),(C+A,0,D); () used to illustrate each vertex.

Note that for horizontal surfaces, any corner may be chosen as the starting corner. The order of vertices determines whether the surface is facing up or down. Shading surfaces are mirrored automatically unless the user specifies "DoNotMirrorDetachedShading", so each shading surface need only be described once.

Thus, another shading surface will be created (facing down):

4,(C+A,-B,D),(C+A,0,D),(C,0,D),(C,-B,D);

IDF example of attached shading surfaces (overhang, fin):

## 1.9.60 ShadingProperty:Reflectance

Specifies the reflectance properties of a shading surface when the solar reflection calculation has requested, i.e., when if "WithReflections" option is chosen in the Building object (ref: Building - Field: Solar Distribution). It is assumed that shading surfaces are divided into an unglazed, diffusely reflecting portion and a glazed, specularly-reflecting portion, either of which may be zero. The reflectance properties are assumed to be the same on both sides of the shading surface.

Note that a shadowing transmittance schedule (ref: Shading Surfaces, Field: Transmittance Schedule Name) can be used with a reflective shading surface. However, EnergyPlus assumes that the reflectance properties of the shading surface are constant even if the transmittance varies.

If no ShadingProperty:Reflectance objects are entered, the default values shown here will be used for shading surfaces. Other surfaces have their reflectance properties defined by the materials in the outer layers of the constructions.

### 1.9.60.1 Field: Shading Surface Name

The name of the Shading:Site, Shading:Building, Shading:Site:Detailed, Shading:Building:Detailed, Shading:Overhang, Shading:Overhang:Projection, Shading:Fin, Shading:Fin:Projection or Shading:Zone:Detailed object to which the following fields apply.

If this ShadingProperty:Reflectance object is not defined for a shading surface the default values listed in each of the following fields will be used in the solar reflection calculation.

### 1.9.60.2 Field: Diffuse Solar Reflectance of Unglazed Part of Shading Surface

The diffuse solar reflectance of the unglazed part of the shading surface (default = 0.2). This reflectance is assumed to be the same for beam-to-diffuse and diffuse-to-diffuse reflection. Beam-to-diffuse reflection is assumed to be independent of angle of incidence of beam radiation. Diffuse-to-diffuse reflection is assumed to be independent of angular distribution of the incident of diffuse radiation. The outgoing diffuse radiation is assumed to be isotropic (hemispherically uniform).

The sum of this reflectance and the shading surface transmittance should be less than or equal to 1.0.

### 1.9.60.3 Field: Diffuse Visible Reflectance of Unglazed Part of Shading Surface

The diffuse visible reflectance of the unglazed part of the shading surface (default = 0.2). This reflectance is assumed to be the same for beam-to-diffuse and diffuse-to-diffuse reflection. Beam-to-diffuse reflection is assumed to be independent of angle of incidence of beam radiation. Diffuse-to-diffuse reflection is assumed to be independent of angular distribution of the incident of diffuse radiation. The outgoing diffuse radiation is assumed to be isotropic (hemispherically uniform).

This value is used only for the daylighting calculation (ref: Daylighting:Controls). The sum of this reflectance and the shading surface transmittance should be less than or equal to 1.0.

### 1.9.60.4 Field: Fraction of Shading Surface That Is Glazed

The fraction of the area of the shading surface that consists of windows (default = 0.0). It is assumed that the windows are evenly distributed over the surface and have the same glazing construction (see following "Name of Glazing Construction"). This might be the case, for example, for reflection from the façade of a neighboring, highly-glazed building. For the reflection calculation the possible presence of shades, screens or blinds on the windows of the shading surface is ignored. Beam-to-beam (specular) reflection is assumed to occur only from the glazed portion of the shading surface. This reflection depends on angle of incidence as determined by the program from the glazing construction. Beam-to-diffuse reflection from the glazed portion is assumed to be zero. The diffuse-to-diffuse reflectance of the glazed portion is determined by the program from the glazing construction.

### 1.9.60.5 Field: Glazing Construction Name

The name of the construction of the windows on the shading surface. Required if Fraction of Shading Surface That Is Glazed is greater than 0.0.

### 1.9.61 WindowProperty:ShadingControl

Window shading with coverings like drapes, blinds, screens or pull-down shades can be used to reduce the amount of solar radiation entering the window or reduce daylighting glare. It can also be used to reduce heat loss through the window (movable insulation). Leaving the window covering open in the winter can maximize solar heat gain and thereby reduce heating loads.

With WindowProperty:ShadingControl—which is referenced by windows and glass doors (ref: FenestrationSurface:Detailed with Type = Window or GlassDoor)—you specify the type and location of the shading device, what variable or combination of variables controls deployment of the shading device, and what the control setpoint is. If the shading device is a blind, you also specify how the slat angle is controlled.

NOTE: WindowProperty:ShadingControl does not work with complex fenestration systems. Controlled complex fenestration systems can be made only with Energy Management Systems objects. Inserting WindowProperty:ShadingControl in FenestrationSurface:Detailed while using complex fenestration systems will be ignored by program.

As shown in Figure 34, a shading device can be inside the window (Shading Type = InteriorShade or InteriorBlind), outside the window (Shading Type = ExteriorShade or ExteriorBlind), or between panes of glass (Shading Type = BetweenGlassShade or BetweenGlassBlind). The exception is window screens which can only be outside the window (Shading Type = ExteriorScreen).

Figure 34. Allowed locations of a window shading device.

When a shading device is present it is either retracted or activated. When it is retracted it covers none of the window. When it is activated it covers the entire glazed part of the window (but not the frame). Whether the shading device is retracted or activated in a particular timestep depends on the control mechanism: see “Shading Control Type,” below. To model a case in which the shading device, when activated, covers only **part** of the window you will have to divide the window into two separate windows, one with the shading device and one without the shading device.

A shading device can also be of a kind in which the optical properties of the glazing switch from one set of values to another in order to increase or decrease solar or visible transmittance (Shading Type = SwitchableGlazing).

There are two ways of specifying the actual shading device:

#### 1.9.61.1 Specify “Name of Construction with Shading”

This is the name of a window Construction that has the shading device as one of its layers. The thermal and solar-optical properties of the shading device are given by the shading material referenced in that Construction (ref: Construction, WindowMaterial:Shade, WindowMaterial:Screen and WindowMaterial:Blind). To use this method you have to define two Constructions for the window, one without the shading device and one with it. See Example 1, below.

The Construction without the shading device is referenced in the FenestrationSurface:Detailed input for the window (see IDF example, below). The Construction with the shading device is referenced by the window’s WindowProperty:ShadingControl.

For Shading Type = InteriorShade, InteriorBlind, ExteriorShade, ExteriorScreen and ExteriorBlind these two Constructions must be identical except for the presence of the shading layer in the shaded Construction, otherwise you will get an error message. You will also get an error message if the Construction referenced by the window has a shading layer.

### 1.9.61.2 Specify the “Material Name of the Shading Device”

This is the name of a WindowMaterial:Shade, WindowMaterial:Screen or WindowMaterial:Blind. This method can be used with Shading Type = InteriorShade, InteriorBlind, ExteriorShade and ExteriorBlind. It cannot be used with Shading Type = BetweenGlassShade, BetweenGlassBlind, or SwitchableGlazing. If Shading Type = InteriorShade or ExteriorShade, then you specify the name of a WindowMaterial:Shade. If Shading Type = InteriorBlind or ExteriorBlind, then you specify the name of a WindowMaterial:Blind. If Shading Type = ExteriorScreen, then you specify the name of a WindowMaterial:Screen. See Example 2, below. This method is simpler to use since you don't have to specify two Constructions that differ only by the shading layer.

When this method is used, the program will automatically create a shaded window construction by adding a shading layer to the outside or inside of the construction corresponding to the window referencing the WindowProperty:ShadingControl. The name, created by the program, of this shaded construction is composed as follows: if the name of the window construction is CCC and the material name of the shading device is DDD, then the shaded construction name is CCC:DDD:INT for an interior shading device and CCC:DDD:EXT for an exterior shading device.

This method is the required if you want to add a shading device to a construction brought in from a WINDOW Data File (ref:Construction:WindowDataFile).

Note that if both “Name of Construction with Shading” and “Material Name of Shading Device” are specified, the former takes precedence.

Most Shading Control Types allow you to specify a schedule that determines when the control is active. One example is a control that is active seasonally. For example, to deploy shading only in the summer when the incident solar is high enough, use Shading Control Type = OnIfHighSolarOnWindow with a schedule that is 1 during the summer months and 0 otherwise and specify Shading Control Is Scheduled = YES.

In addition, most Shading Control Types also allow you to specify that glare control is active in addition to the specified Control Type. For example, you might want to deploy shading when the solar incident on a window is too high OR the glare from the window is too high. This type of joint control requires that the window be in a daylight zone, that the maximum allowed glare be specified in the Daylighting object for the zone, and that Glare Control Is Active = YES in WindowProperty:ShadingControl.

If Shading Type = InteriorBlind, ExteriorBlind or BetweenGlassBlind you can use WindowProperty:ShadingControl to specify how the slat angle of the blind is controlled when the blind is in place.

A special type of WindowProperty:ShadingControl is SwitchableGlazing. An example is electrochromic glazing in which the transmittance and reflectance of the glass is controlled electronically. For example, you could have electrochromic glazing switch from clear (high transmittance) to dark (low transmittance) to control solar gain. If you choose the Shading Type = SwitchableGlazing option for WindowProperty:ShadingControl, the unswitched (clear) state is specified by the Construction referenced by the window and the switched (dark) state is specified by the Construction referenced by WindowProperty:ShadingControl for that window. For example, if you specify Shading Type = SwitchableGlazing and Shading Control Type = OnIfHighSolarOnWindow, then the glazing will switch to the dark state whenever the solar radiation striking the window exceeds the Setpoint value.

For Shading Type = SwitchableGlazing the state of the window is either clear (unswitched) or dark (fully switched) for all Shading Control Types except MeetDaylightIlluminanceSetpoint. In this case, the transmittance of the glazing is adjusted to just meet the daylight illuminance set point at the first daylighting reference point (see Daylighting). This type of control assures that there is just enough solar gain to meet the daylighting requirements in a zone, and no more, thus reducing the cooling load.

### 1.9.61.3 Field: Name

Name of the window shading control. It is referenced by a window (ref: Field: Shading Control Name).

### 1.9.61.4 Field: Shading Type

The type of shading device. The choices are:

*InteriorShade:* A diffusing shade is on the inside of the window. (In the shaded Construction the shading layer must be a WindowMaterial:Shade.)

*ExteriorShade:* A diffusing shade is on the outside of the window. (In the shaded Construction the shading layer must be a WindowMaterial:Shade.)

*BetweenGlassShade:* A diffusing shade is between two glass layers. (In the shaded Construction the shading layer must be a WindowMaterial:Shade.) This shading type is allowed only for double- and triple-glazing. For triple-glazing the shade must be between the two inner glass layers.

*ExteriorScreen:* An insect screen is on the outside of the window. (In the shaded Construction the shading layer must be a WindowMaterial:Screen.)

*InteriorBlind:* A slat-type shading device, such as a Venetian blind, is on the inside of the window. (In the shaded Construction the shading layer must be a WindowMaterial:Blind.)

*ExteriorBlind:* A slat-type shading device is on the outside of the window. (In the shaded Construction the shading layer must be a WindowMaterial:Blind.)

*BetweenGlassBlind:* A slat-type shading device is between two glass layers. (In the shaded Construction the shading layer must be a WindowMaterial:Blind.) This shading type is allowed only for double- and triple-glazing. For triple-glazing the blind must be between the two inner glass layers.

*SwitchableGlazing:* Shading is achieved by changing the characteristics of the window glass, such as by darkening it.

### 1.9.61.5 Field: Construction with Shading Name

Name of the window Construction that has the shading in place. The properties of the shading device are given by the shading material referenced in that Construction (ref: Construction, WindowMaterial:Shade, WindowMaterial:Screen and WindowMaterial:Blind). For Shading Type = SwitchableGlazing, this is the name of the Construction that corresponds to the window in its fully-switched (darkest) state.

Specifying "Name of Construction with Shading" is required if Shading Type = BetweenGlassShade, BetweenGlassBlind, or SwitchableGlazing. For other Shading Types, you may alternatively specify "Material Name of Shading Device" (see below).

#### 1.9.61.6 Field: Shading Control Type

Specifies how the shading device is controlled, i.e., it determines whether the shading device is "on" or "off." For blinds, screens and shades, when the device is "on" it is assumed to cover all of the window except its frame; when the device is "off" it is assumed to cover none of the window (whether "on" or "off" the shading device is assumed to cover none of the wall that the window is on).

For switchable glazing, "on" means that the glazing is in the fully-switched state and "off" means that it is in the unswitched state; for example, for electrochromic glazing, "on" means the glazing is in its darkest state and "off" means it is in its lightest state.

The choices for Shading Control Type are the following. If SetPoint is applicable its units are shown in parentheses.

*AlwaysOn*: Shading is always on.

*AlwaysOff*: Shading is always off.

The following six control types are used primarily to reduce zone cooling load due to window solar gain.

*OnIfScheduleAllows*: Shading is on if schedule value is non-zero. Requires that Schedule Name be specified and Shading Control Is Scheduled = Yes.

Note: For exterior window screens *AlwaysOn*, *AlwaysOff*, and *OnIfScheduleAllows* are the only valid shading control types.

*OnIfHighSolarOnWindow*: Shading is on if beam plus diffuse solar radiation incident on the window exceeds SetPoint ( $W/m^2$ ) and schedule, if specified, allows shading.

*OnIfHighHorizontalSolar*: Shading is on if total (beam plus diffuse) horizontal solar irradiance exceeds SetPoint ( $W/m^2$ ) and schedule, if specified, allows shading.

*OnIfHighOutdoorAirTemperature*: Shading is on if outside air temperature exceeds SetPoint (C) and schedule, if specified, allows shading.

*OnIfHighZoneAirTemperature*: Shading is on if zone air temperature in the previous timestep exceeds SetPoint (C) and schedule, if specified, allows shading.

*OnIfHighZoneCooling*: Shading is on if zone cooling rate in the previous timestep exceeds SetPoint (W) and schedule, if specified, allows shading.

*OnIfHighGlare*: Shading is on if the total daylight glare index at the zone's first daylighting reference point from all of the exterior windows in the zone exceeds the maximum glare index specified in the daylighting input for zone (ref: Group – Daylighting). Applicable only to windows in zones with daylighting.

Note: Unlike other Shading Control Types, glare control is active whether or not a schedule is specified.

*MeetDaylightIlluminanceSetpoint*: Used only with ShadingType = SwitchableGlazing in zones with daylighting controls. In this case the transmittance of the glazing is adjusted to just meet the daylight illuminance set point at the first daylighting reference point. Note that the daylight illuminance set point is specified in the Daylighting:Controls object for the Zone; it is not specified as a WindowProperty:ShadingControl SetPoint. When the glare control is active, if meeting the daylight illuminance set point at the first daylighting reference point results in higher discomfort glare index (DGI) than the specified zone's maximum allowable DGI for either of the daylight reference points, the glazing will be further dimmed until the DGI equals the specified maximum allowable value.

The following three control types can be used to reduce zone heating load during the winter by reducing window conductive heat loss at night and leaving the window unshaded during the day to maximize solar gain. They are applicable to any Shading Type except ExteriorScreen but are most appropriate for interior or exterior shades with high insulating value ("movable insulation"). "Night" means the sun is down and "day" means the sun is up.

*OnNightIfLowOutdoorTempAndOffDay*: Shading is on at night if the outside air temperature is less than SetPoint (C) and schedule, if specified, allows shading. Shading is off during the day.

*OnNightIfLowInsideTempAndOffDay*: Shading is on at night if the zone air temperature in the previous timestep is less than SetPoint (C) and schedule, if specified, allows shading. Shading is off during the day.

*OnNightIfHeatingAndOffDay*: Shading is on at night if the zone heating rate in the previous timestep exceeds SetPoint (W) and schedule, if specified, allows shading. Shading is off during the day.

The following two control types can be used to reduce zone heating and cooling load. They are applicable to any Shading Type except ExteriorScreen but are most appropriate for translucent interior or exterior shades with high insulating value ("translucent movable insulation").

*OnNightIfLowOutdoorTempAndOnDayIfCooling*: Shading is on at night if the outside air temperature is less than SetPoint (C). Shading is on during the day if the zone cooling rate in the previous timestep is non-zero. Night and day shading is subject to schedule, if specified.

*OnNightIfHeatingAndOnDayIfCooling*: Shading is on at night if the zone heating rate in the previous timestep exceeds SetPoint (W). Shading is on during the day if the zone cooling rate in the previous timestep is non-zero. Night and day shading is subject to schedule, if specified.

The following control types can be used to reduce zone cooling load. They are applicable to any Shading Type except ExteriorScreen but are most appropriate for interior or exterior blinds, interior or exterior shades with low insulating value, or switchable glazing.

*OffNightAndOnDayIfCoolingAndHighSolarOnWindow*: Shading is off at night. Shading is on during the day if the solar radiation incident on the window exceeds SetPoint (W/m<sup>2</sup>) and if the zone cooling rate in the previous timestep is non-zero. Daytime shading is subject to schedule, if specified.

*OnNightAndOnDayIfCoolingAndHighSolarOnWindow*: Shading is on at night. Shading is on during the day if the solar radiation incident on the window exceeds SetPoint (W/m<sup>2</sup>) and if the zone cooling rate in the previous timestep is non-zero. Day and night shading is subject to schedule, if specified. (This Shading Control Type is the same as the previous one, except the shading is on at night rather than off.)

*OnIfHighOutdoorAirTempAndHighSolarOnWindow*: Shading is on if the outside air temperature exceeds the Setpoint (C) and if the solar radiation incident on the window exceeds SetPoint 2 (W/m<sup>2</sup>).

*OnIfHighOutdoorAirTempAndHighHorizontalSolar*: Shading is on if the outside air temperature exceeds the Setpoint (C) and if the horizontal solar radiation exceeds SetPoint 2 (W/m<sup>2</sup>).

#### 1.9.61.7 Field: Schedule Name

Required if Shading Control Is Scheduled = Yes. If schedule value > 0, shading control is active, i.e., shading can be on only if the shading control test passes. If schedule value = 0, shading is off whether or not the control test passes. If Schedule Name is not specified, shading control is assumed to be active at all times.

#### 1.9.61.8 Field: Setpoint

The setpoint for activating window shading. The units depend on the type of trigger:

- W/m<sup>2</sup> for solar-based controls
- W for cooling- or heating-based controls
- Degrees C for temperature-based controls

SetPoint is unused for Shading Control Type = OnIfScheduleAllows, OnIfHighGlare and DaylightIlluminance.

#### 1.9.61.9 Field: Shading Control Is Scheduled

Accepts values YES and NO. The default is NO. Not applicable for Shading Control Type = OnIfHighGlare and should be blank in that case.

If YES, Schedule Name is required and that schedule determines whether the shading control specified by Shading Control Type is active or inactive (see Schedule Name, above).

If NO, Schedule Name is not applicable (should be blank) and the shading control is unscheduled.

Shading Control Is Scheduled = YES is required if Shading Control Type = OnIfScheduleAllows.

#### 1.9.61.10 Field: Glare Control Is Active

Accepts values YES and NO. The default is NO.

If YES and the window is in a daylight zone, shading is on if the zone's discomfort glare index exceeds the maximum discomfort glare index specified in the Daylighting object referenced by the zone. For switchable windows with *MeetDaylightIlluminanceSetpoint* shading control, if Glare Control is active, the windows are always continuously dimmed as necessary to meet the zone's maximum allowable DGI while providing appropriate amount of daylight for the zone.

The glare test is OR'ed with the test specified by Shading Control Type. For example, if Glare Control Is Active = YES and Shading Control Type = OnIfHighZoneAirTemp, then shading is on if glare is too high OR if the zone air temperature is too high.

Glare Control Is Active = YES is required if Shading Control Type = OnIfHighGlare.

#### 1.9.61.11 Field: Shading Device Material Name

The name of a WindowMaterial:Shade, WindowMaterial:Screen or WindowMaterial:Blind. Required if "Name of Construction with Shading" is not specified. Not applicable if Shading Type = BetweenGlassShade, BetweenGlassBlind or SwitchableGlazing and should be blank in this case. If both "Name of Construction with Shading" and "Material Name of Shading Device" are entered the former takes precedence.

#### 1.9.61.12 Field: Type of Slat Angle Control for Blinds

Applies only to Shading Type = InteriorBlind, ExteriorBlind or BetweenGlassBlind. Specifies how the slat angle is controlled. The choices are FixedSlatAngle, ScheduledSlatAngle and BlockBeamSolar.

If FixedSlatAngle (the default), the angle of the slat is fixed at the value input for the WindowMaterial:Blind that is contained in the construction specified by Name of Construction with Shading or is specified by Material Name of Shading Device.

If ScheduledSlatAngle, the slat angle varies according to the schedule specified by Slat Angle Schedule Name, below.

If BlockBeamSolar, the slat angle is set each timestep to just block beam solar radiation. If there is no beam solar on the window the slat angle is set to the value input for the WindowMaterial:Blind that is contained in the construction specified by Name of Construction with Shading or is specified by Material Name of Shading Device. The BlockBeamSolar option prevents beam solar from entering the window and causing possible unwanted glare if the beam falls on work surfaces while at the same time allowing near-optimal indirect radiation for daylighting.

### 1.9.61.13 Field: Slat Angle Schedule Name

This is the name of a schedule of slat angles that is used when Type of Slat Angle Control for Blinds = ScheduledSlatAngle. You should be sure that the schedule values fall within the range given by the Minimum Slat Angle and Maximum Slat Angle values entered in the corresponding WindowMaterial:Blind. If not, the program will force them into this range.

### 1.9.61.14 Field: Setpoint 2

Used only as the second setpoint for the following two-setpoint control types: OnIfHighOutdoorAirTempAndHighSolarOnWindow, OnIfHighOutdoorAirTempAndHighHorizontalSolar, OnIfHighZoneAirTempAndHighSolarOnWindow,

and OnIfHighZoneAirTempAndHighHorizontalSolar

An IDF example: window with interior roll shade that is deployed when solar incident on the window exceeds 50 W/m<sup>2</sup>.

## 1.9.62 WindowProperty:FrameAndDivider

The WindowProperty:FrameAndDivider object is referenced by exterior windows that have

- a frame, and/or
- a divider, and/or
- reveal surfaces that reflect beam solar radiation.

A **frame** surrounds the glazing in a window (see Figure 35 and Figure 36). It is assumed that all frame characteristics—such as width, conductance and solar absorptance—are the same for the top, bottom and side elements of the frame. If the frame elements are not the same then you should enter area-weighted average values for the frame characteristics.

The window vertices that you specify in the FenestrationSurface:Detailed object are those of the glazed part of the window, not the frame. EnergyPlus automatically subtracts the area of the frame—determined from the glazing dimensions and the frame width—from the area of the wall containing the window.

A **divider**, as shown in Figure 35, Figure 36 and Figure 37, divides the glazing up into separate lites. It is assumed that all divider elements have the same characteristics. If not, area-weighted average values should be used. EnergyPlus automatically subtracts the divider area from the glazed area of the window.

**Reveal surfaces**, as shown in Figure 38, are associated with the setback of the glazing from the outside and/or inside surface of the parent wall. If the depth and solar absorptance of these surfaces are specified, the program will calculate the reflection of beam solar radiation from these surfaces. The program also calculates the shadowing (onto the window) of beam and diffuse solar radiation by outside reveal surfaces.

In EnergyPlus, a window can have any combination of frame, divider and reveal surfaces, or none of these.

The best source of frame and divider characteristics is the WINDOW program, which will calculate the values required by EnergyPlus for different frame and divider types. In particular, the THERM program within the WINDOW program will calculate the effective conductance of frames and dividers; this is the conductance taking 2-D heat transfer effects into account.

Note that a window's frame and divider characteristics, along with other window information, can be read in from the Window Data File (see "Importing Windows from the WINDOW program" and "Construction:WindowDataFile object"). In this case the WindowProperty:FrameAndDivider referenced by the window is not applicable and should be blank unless you want to specify reveal surfaces for beam solar reflection.

Figure 35. A window with a frame and divider.

In the illustration above, the divider has two horizontal elements and one vertical element.

#### 1.9.62.1 Field: Name

The name of the frame/divider object. It is referenced by WindowProperty:FrameAndDivider Name in FenestrationSurface:Detailed.

#### Frame Fields

#### 1.9.62.2 Field: Frame Width

The width of the frame elements when projected onto the plane of the window. It is assumed that the top, bottom and side elements of the frame have the same width. If not, an average frame width should be entered such that the projected frame area calculated using the average value equals the sum of the areas of the frame elements.

#### 1.9.62.3 Field: Frame Outside Projection

The amount by which the frame projects outward from the outside surface of the window glazing. If the outer surface of the frame is flush with the glazing, Frame Outside Projection = 0.0. Used to calculate shadowing of frame onto glass, solar absorbed by frame, IR emitted and absorbed by frame, and convection from frame.

#### 1.9.62.4 Field: Frame Inside Projection

The amount by which the frame projects inward from the inside surface of the window glazing. If the inner surface of the frame is flush with the glazing, Frame Inside Projection = 0.0. Used to calculate solar absorbed by frame, IR emitted and absorbed by frame, and convection from frame.

Figure 36. Illustration showing frame and divider dimensioning.

**1.9.62.5 Field: Frame Conductance**

The effective thermal conductance of the frame measured from inside to outside frame surface (no air films) and taking 2-D conduction effects into account. Obtained from the WINDOW program or other 2-D calculation.

**1.9.62.6 Field: Ratio of Frame-Edge Glass Conductance to Center-Of-Glass Conductance**

The glass conductance near the frame (excluding air films) divided by the glass conductance at the center of the glazing (excluding air films). Used only for multi-pane glazing constructions. This ratio is greater than 1.0 because of thermal bridging from the glazing across the frame and across the spacer that separates the glass panes. Values can be obtained from the WINDOW program the user-selected glazing construction and frame characteristics.

**1.9.62.7 Field: Frame Solar Absorptance**

The solar absorptance of the frame. The value is assumed to be the same on the inside and outside of the frame and to be independent of angle of incidence of solar radiation. If solar reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials).

**1.9.62.8 Field: Frame Visible Absorptance**

The visible absorptance of the frame. The value is assumed to be the same on the inside and outside of the frame and to be independent of angle of incidence of solar radiation. If visible reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials).

**1.9.62.9 Field: Frame Thermal Hemispherical Emissivity**

The thermal emissivity of the frame, assumed the same on the inside and outside.

***Divider Fields***

**1.9.62.10 Field: Divider Type**

The type of divider (see figure below). Divider Type = Suspended is applicable only to multi-pane glazing. It means that the divider is suspended between the

panes. (If there are more than two glass layers, the divider is assumed to be placed between the two outermost layers.)

Divider Type = DividedLite means that the divider elements project out from the outside and inside surfaces of the glazing and divide the glazing into individual lites. For multi-pane glazing, this type of divider also has between-glass elements that separate the panes.

Figure 37. Illustration showing divider types.

#### 1.9.62.11 Field: Divider Width

The width of the divider elements when projected onto the plane of the window. It is assumed that the horizontal and vertical divider elements have the same width. If not, an average divider width should be entered such that the projected divider area calculated using the average value equals the sum of the areas of the divider elements.

#### 1.9.62.12 Field: Number of Horizontal Dividers

The number of divider elements parallel to the top and bottom of the window.

#### 1.9.62.13 Field: Number of Vertical Dividers

The number of divider elements parallel to the sides of the window.

#### 1.9.62.14 Field: Divider Outside Projection

The amount by which the divider projects out from the outside surface of the window glazing. For Divider Type = Suspended, Divider Projection = 0.0. Used to calculate shadowing of divider onto glass, solar absorbed by divider, IR emitted and absorbed by divider, and convection from divider.

#### 1.9.62.15 Field: Divider Inside Projection

The amount by which the divider projects inward from the inside surface of the window glazing. If the inner surface of the divider is flush with the glazing, Divider Inside Projection = 0.0. Used to calculate solar absorbed by divider, IR emitted and absorbed by divider, and convection from divider.

#### 1.9.62.16 Field: Divider Conductance

The effective thermal conductance of the divider measured from inside to outside divider surface (no air films) and taking 2-D conduction effects into account. Obtained from the WINDOW program or other 2-D calculation.

#### 1.9.62.17 Field: Ratio of Divider-Edge Glass Conductance to Center-Of-Glass Conductance

The glass conductance near the divider (excluding air films) divided by the glass conductance at the center of the glazing (excluding air films). Used only for multi-pane glazing constructions. This ratio is greater than 1.0 because of thermal bridging from the glazing across the divider and across the spacer that separates the glass panes. Values can be obtained from the WINDOW program for the user-selected glazing construction and divider characteristics.

#### 1.9.62.18 Field: Divider Solar Absorptance

The solar absorptance of the divider. The value is assumed to be the same on the inside and outside of the divider and to be independent of angle of incidence of solar radiation. If solar reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials).

#### 1.9.62.19 Field: Divider Visible Absorptance

The visible absorptance of the divider. The value is assumed to be the same on the inside and outside of the divider and to be independent of angle of incidence of solar radiation. If visible reflectance (or reflectivity) data is available, then absorptance is equal to 1.0 minus reflectance (for opaque materials).

#### 1.9.62.20 Field: Divider Thermal Hemispherical Emissivity

The thermal emissivity of the divider, assumed the same on the inside and outside.

#### **Reveal Surface Fields**

The following fields specify the properties of the window reveal surfaces (reveals occur when the window is not in the same plane as the base surface). From this information and from the geometry of the window and the sun position, the program calculates beam solar radiation absorbed and reflected by the top, bottom, right and left sides of outside and inside window reveal surfaces. In doing this calculation, the shadowing on a reveal surface by other reveal surfaces is determined using the orientation of the reveal surfaces and the sun position.

It is assumed that:

- The window is an exterior window.
- The reveal surfaces are perpendicular to the window plane.
- If an exterior shade, screen or blind is in place it shades exterior and interior reveal surfaces so that in this case there is no beam solar on these surfaces.
- If an interior shade or blind is in place it shades the interior reveal surfaces so that in this case there is no beam solar on these surfaces.
- The possible shadowing on inside reveal surfaces by a window divider is ignored.
- The outside reveal surfaces (top, bottom, left, right) have the same solar absorptance and depth. This depth is not input here but is automatically determined by the program—from window and wall vertices—as the distance between the plane of the outside face of the glazing and plane of the outside face of the parent wall.
- The inside reveal surfaces are divided into two categories: (1) the bottom reveal surface, called here the "inside sill;" and (2) the other reveal surfaces (left, right and top).
- The left, right and top inside reveal surfaces have the same depth and solar absorptance. The inside sill is allowed to have depth and solar absorptance values that are different from the corresponding values for the other inside reveal surfaces.
- The inside sill depth is required to be greater than or equal to the depth of the other inside reveal surfaces. If the inside sill depth is greater than zero the depth of the other inside reveal surfaces is required to be greater than zero.
- The reflection of beam solar radiation from all reveal surfaces is assumed to be isotropic diffuse; there is no specular component.
- Half of the beam solar reflected from outside reveal surfaces is goes towards the window; the other half goes back to the exterior environment (i.e., reflection of this outward-going component from other outside reveal surfaces is not considered).
- The half that goes towards the window is added to the other solar radiation incident on the window. Correspondingly, half of the beam solar reflected from inside reveal surfaces goes towards the window, with the other half going into the zone. The portion going towards the window that is not reflected is absorbed in the glazing or is transmitted back out into the exterior environment.
- The beam solar that is absorbed by outside reveal surfaces is added to the solar absorbed by the outside surface of the window's parent wall; similarly, the beam solar absorbed by the inside reveal surfaces is added to the solar absorbed by the inside surface of the parent wall.

The net effect of beam solar reflected from outside reveal surfaces is to increase the heat gain to the zone, whereas the effect of beam solar reflected from inside reveal surfaces is to decrease the heat gain to the zone since part of this reflected solar is transmitted back out the window.

If the window has a frame, the absorption of reflected beam solar by the inside and outside surfaces of the frame is considered. The shadowing of the frame onto interior reveal surfaces is also considered.

#### **1.9.62.21 Field: Outside Reveal Solar Absorptance**

The solar absorptance of outside reveal surfaces.

#### **1.9.62.22 Field: Inside Sill Depth**

The depth of the inside sill, measured from the inside surface of the glazing to the edge of the sill (see Figure 38).

#### **1.9.62.23 Field: Inside Sill Solar Absorptance**

The solar absorptance of the inside sill.

#### ***Field: Inside Reveal Depth***

The depth of the inside reveal surfaces other than the sill, measured from the inside surface of the glazing to the edge of the reveal surface (see Figure 38).

#### **1.9.62.24 Field: Inside Reveal Solar Absorptance**

The solar absorptance of the inside reveal surfaces other than the sill.

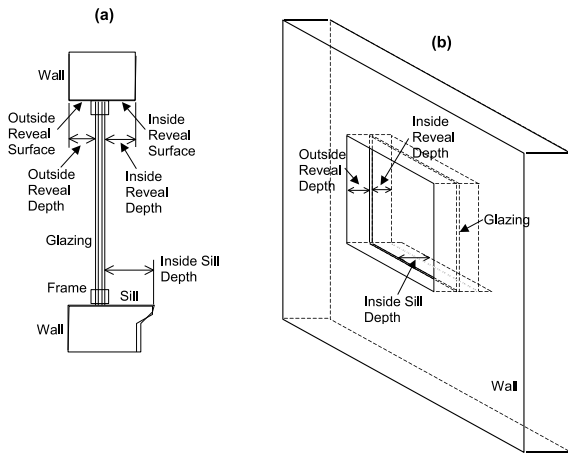

Figure 38. (a) Vertical section through a window (with frame) showing outside and inside reveal surfaces and inside sill. (b) Perspective view looking from the outside of a window (without frame) showing reveal surfaces. Note that “Outside Reveal Depth” is not a user input; it is calculated by the program from the window and wall vertices.

### 1.9.63 WindowProperty:AirflowControl

This object is used to specify the control mechanism for windows in which forced air flows in the gap between adjacent layers of glass. Such windows are called “airflow windows.” They are also known as “heat-extract windows” or “climate windows.”

A common application is to reduce the zone load by exhausting indoor air through the window. In the cooling season this picks up and expels some of the solar heat absorbed by the window glass (and by the between-glass shade or blind, if present). In the heating season this warms the window, reducing the heat loss from the window. A side benefit is increased thermal comfort. This is because the inside surface of the window will generally be cooler in summer and warmer in winter.

The surface output variable “Surface Window Gap Convective Heat Transfer Rate” gives the heat picked up (or lost) by the gap airflow.

#### 1.9.63.1 Field: Name

Name of the window that this WindowProperty:AirflowControl refers to. It must be a window with two or three glass layers, i.e., double- or triple-glazing. For triple-glazing the airflow is assumed to be between the two inner glass layers.

An error will result if the gas in the airflow gap is other than air. If an airflow window has a between-glass shade or blind, the gas in the gap on either side of the shade or blind must be air.

#### 1.9.63.2 Field: Airflow Source

The source of the gap airflow. The choices are:

*IndoorAir*: Indoor air from the window's zone is passed through the window.

*OutdoorAir*: Outdoor air is passed through the window.

### 1.9.63.3 Field: Airflow Destination

This is where the gap air goes after passing through the window. The choices are:

*IndoorAir*: The gap air goes to the indoor air of the window's zone.

*OutdoorAir*: The gap air goes to the outside air.

*ReturnAir*: The gap air goes to the return air for the window's zone. This choice is allowed only if Airflow Source = InsideAir. If the return air flow is zero, the gap air goes to the indoor air of the window's zone. If the sum of the gap airflow for all of the windows in a zone with Airflow Destination = ReturnAir exceeds the return airflow, then the difference between this sum and the return airflow goes to the indoor air.

Figure 39 shows the allowed combinations of Airflow Source and Airflow Destination. The allowed combinations of Airflow Source and Airflow Destination are:

IndoorAir -> OutdoorAir

IndoorAir -> IndoorAir

IndoorAir -> ReturnAir

OutdoorAir -> IndoorAir

OutdoorAir -> OutdoorAir

### 1.9.63.4 Field: Maximum Flow Rate

The maximum value of the airflow, in  $\text{m}^3/\text{s}$  per m of glazing width. The value is typically 0.006 to 0.009  $\text{m}^3/\text{s}\cdot\text{m}$  (4 to 6  $\text{cfm}/\text{ft}$ ).

The airflow can be modulated by specifying Airflow Has Multiplier Schedule = Yes and giving the name of the Airflow Multiplier Schedule (see below).

The fan energy used to move the air through the gap is generally very small and so is ignored.

### 1.9.63.5 Field: Airflow Control Type

Specifies how the airflow is controlled. The choices are:

*AlwaysOnAtMaximumFlow*: The airflow is always equal to Maximum Airflow.

*AlwaysOff*: The airflow is always zero.

*ScheduledOnly*: The airflow in a particular timestep equals Maximum Airflow times the value of the Airflow Multiplier Schedule for that timestep.

### 1.9.63.6 Field: Airflow Is Scheduled

Specifies if the airflow is scheduled. The choices are:

*Yes*: The airflow is scheduled.

*No*: The airflow is not scheduled.

If Yes, Airflow Multiplier Schedule Name is required.

### 1.9.63.7 Field: Airflow Multiplier Schedule Name

The name of a schedule with values between 0.0 and 1.0. The timestep value of the airflow is Maximum Airflow times the schedule value. Required if Airflow Is Scheduled = Yes. Unused if Airflow Is Scheduled = No. This schedule should have a ScheduleType with Numeric Type = Continuous and Range = 0.0 : 1.0.

Figure 39. Gap airflow configurations for airflow windows. (a) **Air exhaust window**: Airflow Source = InsideAir, Airflow Destination = OutsideAir; (b) **Indoor air curtain window**: Airflow Source = InsideAir, Airflow Destination = InsideAir; (c) **Air supply window**: Airflow Source = OutsideAir, Airflow Destination = InsideAir; (d) **Outdoor air curtain window**: Airflow Source = OutsideAir, Airflow Destination = OutsideAir; (e) **Airflow to Return Air**: Airflow Source = InsideAir, Airflow Destination = ReturnAir. Based on “Active facades,” Version no. 1, Belgian Building Research Institute, June 2002.

An IDF example: window with a constant airflow from inside to outside at  $0.008 \text{ m}^3/\text{s}\cdot\text{m}$ .

```

### 1.9.64 WindowProperty:StormWindow

This object allows you to assign a movable exterior glass layer (“storm window” or “storm glass”) that is usually applied to a window in the winter to reduce heat loss and removed in the summer. A WindowProperty:StormWindow object is required for each window that has an associated storm window. It is assumed that:

- When the storm glass is in place it is the outermost layer of the window, it covers only the glazed part of the window and not the frame, and it forms a tight seal. See Figure 40.
- When the storm glass is not in place it is completely removed and has no effect on window heat transfer.
- The gap between the storm glass and rest of the glazing is filled with air.

Figure 40. Section through a single-glazed window without (left) and with (right) a storm glass layer. Not to scale.

With the addition of a storm window, single glazing effectively becomes double glazing, double glazing becomes triple glazing, etc.

The presence of a storm window is indicated by the output variable “Surface Storm Window On Off Status” (see “Window Output Variables”). This flag is **0** if the storm window is off, **1** if it is on, and **-1** if the window does not have an associated storm window.

The program automatically creates a window construction (ref: Construction) that consists of the storm window glass layer and its adjacent air layer added to the original (unshaded, or “bare”) window construction. In the eplusout.eio file this construction is called BARECONSTRUCTIONWITHSTORMWIN:*n*, where *n* is the number of the associated StormWin object. If the window has a shaded construction, the program creates a construction called SHADEDCONSTRUCTIONWITHSTORMWIN:*n* that consists of the storm window glass layer and its adjacent air layer added to the original shaded window construction.

The program also creates a WindowMaterial:Gas layer corresponding to the air layer adjacent to the storm glass. In the eplusout.eio file this layer is called

AIR:STORMWIN:kMM, where  $k$  is the thickness of the air layer expressed as an integer number of millimeters.

#### 1.9.64.1 Field: Window Name

This is the name of a window (or glass door) to which the storm glass is applied. Not all windows can accept WindowProperty:StormWindow. The rules are:

- The window must be an exterior window. WindowProperty:StormWindow is not applicable to interior (interzone) windows.
- The window construction (without the storm glass layer) can have up to three glass layers.
- If the window has an associated shaded construction (ref: WindowProperty:ShadingControl), that construction can have an interior shade or blind and up to three glass layers, or a between-glass shade or blind and two glass layers. The shaded construction cannot have an exterior shade or blind, cannot have a between-glass shade or blind and three glass layers, and cannot be switchable glazing.
- The window cannot be an airflow window, i.e., a window that has an associated WindowProperty:AirflowControl.

#### 1.9.64.2 Field: Storm Glass Layer Name

This is the name of a window glass material. Storm windows are assumed to consist of a single layer of glass. A storm window frame, if present, is ignored.

#### 1.9.64.3 Field: Distance Between Storm Glass Layer and Adjacent Glass

The separation between the storm glass and the rest of the window (Figure 40). It is measured from the inside of the storm glass layer to the outside of the adjacent glass layer.

#### 1.9.64.4 Field: Month that Storm Glass Layer Is Put On

The number of the month (January = 1, February = 2, etc.) during which the storm window is put in place.

#### 1.9.64.5 Field: Day of Month that Storm Glass Layer Is Put On

The day of the month that the storm window is put in place. It is assumed that the storm window is put in place at the beginning of this day, i.e., during the first simulation timestep of the day, and remains in place until that month and day given by the following two fields.

#### 1.9.64.6 Field: Month that Storm Glass Layer Is Taken Off

The number of the month (January = 1, February = 2, etc.) during which the storm window is removed.

#### 1.9.64.7 Field: Day of Month that Storm Glass Layer Is Taken Off

The day of the month that the storm window is removed. It is assumed that the storm window is removed at the beginning of this day, i.e., during the first simulation timestep of the day, and stays off until the month and day given by Month that Storm Glass Layer Is Put On, Day of Month that Storm Glass Layer Is Put On.

In the northern hemisphere, the month the storm window is put on is generally greater than the month it is taken off (for example put on in month 10, when it starts to get cold, and taken off in month 5, when it starts to warm up). In the southern hemisphere this is reversed: month on is less than month off.

An IDF example of WindowProperty:StormWindow. The storm window is put in place on October 15 and removed on May 1.

```
WindowProperty:StormWindow,  
Window1, !- Name of Window to Which Storm Window Glass Layer is Applied  
GlassA, !- Name of Material:WindowGlass or MATERIAL:WindowGlass:AltInput that is the storm window layer  
0.060, !- Distance from storm window to adjacent glass (m)  
10, !- Month that Storm Window Is Put On  
15, !- Day of Month that Storm Window Is Put On  
5, !- Month that Storm Window Is Taken Off  
1; !- Day of Month that Storm Window Is Taken Off
```

### 1.9.65 Importing Windows from WINDOW program

WINDOW v6.3 and later is capable of writing IDF excerpts for Window data. This is the preferred method as no external file is necessary. See the Tips document for details on obtaining the IDF excerpt.

The WINDOW program calculates the U-value, Solar Heat Gain Coefficient, solar transmission/absorption characteristics, visible transmission characteristics and other properties of a window under standard indoor and outdoor conditions. WINDOW treats the whole window system—glazing, frame and divider. A sub-program of WINDOW called THERM uses a 2-D finite element calculation to determine the effective conductance of frame, divider and edge-of-glass elements. Another sub-program, OPTICS, determines the solar-optical properties of glazing, including laminates and coated glass.

WINDOW can write a data file containing a description of the window that was analyzed. An example of this file (which is no longer the preferred method) is shown in the Tips document under WINDOW generated files. is shown below. This file, which can be named by the user, can be read by EnergyPlus. For more

complete description and examples, see the object description -- Construction:WindowDataFile.

In this way, the same window that was created in WINDOW can be imported into EnergyPlus for annual energy analysis without having to re-input the window data. To obtain WINDOW, THERM, or OPTICS go to <http://windows.lbl.gov> and choose the software link. A major advantage of using WINDOW to create window input for EnergyPlus is that you will have direct access to WINDOW's expanding database of over 1000 different glass types; and you will be able to browse through this database according to different criteria (color, transmittance, solar heat gain coefficient, etc.) to help you select the best glass type for your application.

Although WINDOW writes only one window entry on the WINDOW data file, EnergyPlus users can combine two or more of these files to end up with a single data file with multiple window entries of different types. In this way a library of windows from WINDOW can be built up if so desired. If you combine files like this you should be sure not to leave out or change any of lines from the original files.

- There are four methods for inputting window constructions in EnergyPlus:

- 1) input full spectral data for each layer in the IDF,
- 2) input spectral average data for each layer in the IDF,
- 3) items 1 and 2 can be accomplished by reporting the IDF excerpt method from WINDOW
- 4) import WINDOW report containing layer-by-layer calculated values and overall glazing system angular values.

**Note: When using method 4, the overall glazing system angular dependent properties, including Tsol, Abs, Rfsol, Rbsol, Tvis, Rfvis, and Rbvis, are not used by EnergyPlus. Therefore, methods 1 and 2 and preferably 3 are recommended.**

- The SHGC calculations in EnergyPlus for window layers input using full spectral data use a spectral weighting data set (derived from Optics5 data file ISO-9845GlobalNorm.std) that is different from the WINDOW default spectral weighting data set (W5\_NFRC\_2003.std). This difference accounts for most of the variation in SHGC values reported by EnergyPlus and WINDOW for full spectral data window layer input. This variation is more pronounced for window constructions of three glass layers or more.
- Users intending to select a window construction based on SHGC value for energy code compliance should base their selection on the value reported by WINDOW since this is the officially recognized value.

In EnergyPlus, the Window data file is searched for each "Construction:WindowDataFile" object in the EnergyPlus input. This object has a very simple form:

```
Construction:WindowDataFile,  
ConstructionName,  
FileName; ! Default is Window5DataFile.dat in the "run" folder.
```

If there is a window called ConstructionName on the Window data file, the data for that window is read from the file and the following EnergyPlus objects and their names are created. The "W5" prefixed to these names indicates that the object originated in the Window data file.

### 1.9.66 Zone Thermal Output(s)

In addition to the canned Surface reports (view the Reports section later in this document) and surface variables (above), the following variables are available for all zones:

- Zone,Sum,Zone Total Internal Radiant Heating Energy [J]
- Zone,Sum,Zone Total Internal Visible Radiation Heating Energy [J]
- Zone,Sum,Zone Total Internal Convective Heating Energy [J]
- Zone,Sum,Zone Total Internal Latent Gain Energy [J]
- Zone,Sum,Zone Total Internal Total Heating Energy [J]
- Zone,Average,Zone Mean Air Temperature [C]
- HVAC,Average,Zone Air Temperature [C]
- Zone,Average,Zone Mean Radiant Temperature [C]
- Zone,Average,Zone Operative Temperature [C]
- HVAC,Sum,Zone Air System Sensible Heating Energy [J]
- HVAC,Sum,Zone Air System Sensible Cooling Energy [J]
- HVAC,Average,Zone Air System Sensible Heating Rate [W]
- HVAC,Average,Zone Air System Sensible Cooling Rate [W]

- HVAC,Average,Zone Air Humidity Ratio[kgWater/kgDryAir]
- HVAC,Average,Zone Air Relative Humidity[%]
- Two of these are of particular interest:
- Zone,Average,Zone Mean Air Temperature [C]
- HVAC,Average,Zone Air Temperature [C]

These two variable outputs are/should be identical. However, note that they can be reported at different time intervals. "Zone Mean Air Temperature" is only available on the Zone/HB timestep (Number of Timesteps per Hour) whereas "Zone Air Temperature" can be reported at the HVAC timestep (which can vary).

#### **1.9.66.1 Zone Mean Air Temperature [C]**

From the code definition, the zone mean air temperature is the average temperature of the air temperatures at the system timestep. Remember that the zone heat balance represents a "well stirred" model for a zone, therefore there is only one mean air temperature to represent the air temperature for the zone.

#### **1.9.66.2 Zone Air Temperature [C]**

This is very similar to the mean air temperature in the last field. The "well stirred" model for the zone is the basis, but this temperature is also available at the "detailed" system timestep.

#### **1.9.66.3 Zone Mean Radiant Temperature [C]**

The Mean Radiant Temperature (MRT) in degrees Celsius of a space is really the measure of the combined effects of temperatures of surfaces within that space. The larger the surface area and the closer one is to it, the more effect the surface temperature of that surface has on each other. The MRT is the measure of all these surface areas and temperatures.

#### **1.9.66.4 Zone Operative Temperature [C]**

Zone Operative Temperature (OT) is the average of the Zone Mean Air Temperature (MAT) and Zone Mean Radiant Temperature (MRT),  $OT = 0.5 \cdot MAT + 0.5 \cdot MRT$ . This output variable is not affected by the type of thermostat controls in the zone, and does not include the direct effect of high temperature radiant systems. See also Zone Thermostat Operative Temperature.

#### **1.9.66.5 Zone Air System Sensible Heating Energy [J]**

This field represents the sensible heating energy in Joules that is actually supplied by the system to that zone for the timestep reported. This is the sensible heating rate multiplied by the simulation timestep. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. . This field is not multiplied by zone or group multipliers.

Zone Air System Sensible Heating (and Cooling) Energy (and Rate) all report the heating or cooling delivered by the HVAC system to a zone. These values are calculated by multiplying the supply air mass flow rate by the difference between the supply air temperature and the zone air temperature. This does not always indicate the operation of heating or cooling coils. For example, cooling will be reported if the supply air is cooled due to the introduction of outside air, even if all coils are off.

Note that these variables are calculated at the system timestep. When reported at the "detailed" reporting frequency, these variable will never show heating and cooling both in the same system timestep. If reported at a frequency less than "Detailed" (for example, Hourly) values may appear in both the heating and cooling variable for the same hour if the system cooled the zone for part of the reporting period and heated the zone for another part of the reporting period.

#### **1.9.66.6 Zone Air System Sensible Cooling Energy [J]**

This field represents the sensible cooling energy in Joules that is actually supplied by the system to that zone for the timestep reported. This is the sensible cooling rate multiplied by the simulation timestep. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers.

#### **1.9.66.7 Zone Air System Sensible Heating Rate [W]**

This field represents the sensible heating rate in Watts that is actually supplied by the system to that zone for the timestep reported. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers.

#### **1.9.66.8 Zone Air System Sensible Cooling Rate [W]**

This field represents the sensible cooling rate in Watts that is actually supplied by the system to that zone for the timestep reported. This is calculated and reported from the Correct step in the Zone Predictor-Corrector module. This field is not multiplied by zone or group multipliers.

#### **1.9.66.9 Zone Air Humidity Ratio[kgWater/kgDryAir]**

This field represents the air humidity ratio after the correct step for each zone. The humidity ratio is the mass of water vapor to the mass of dry air contained in the zone in (kg water/kg air) and is unitless.

#### **1.9.66.10 Zone Air Relative Humidity[%]**

This field represents the air relative humidity ratio after the correct step for each zone. The relative humidity is in percent and uses the Zone Air Temperature, the Zone Air Humidity Ratio and the Outside Barometric Pressure for calculation.

#### **1.9.66.11 Zone Total Internal Radiant Heating Energy [J]**

This field represents the sum of radiant gains from specific internal sources (e.g. equipment) throughout the zone in joules. This includes radiant gain from People, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

#### **1.9.66.12 Zone-Total Internal Visible Heat Gain [J]**

This field expresses the sum of heat gain in joules that is the calculated short wavelength radiation gain from lights in the zones. This calculation uses the total energy from lights and the fraction visible to realize this value, summed over the zones in the simulation.

#### **1.9.66.13 Zone Total Internal Convective Heating Energy [J]**

This field represents the sum of convective gains from specific sources (e.g. equipment) throughout the zone in joules. This includes convective gain from People, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

#### **1.9.66.14 Zone Total Internal Latent Gain Energy [J]**

This field represents the sum of latent gains from specific internal sources (e.g. equipment) throughout the zone in joules. This includes latent gain from People, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

#### **1.9.66.15 Zone Total Internal Total Heating Energy [J]**

This field represents the sum of all heat gains throughout the zone in joules. This includes all heat gains from People, Lights, Electric Equipment, Gas Equipment, Other Equipment, Hot Water Equipment, and Steam Equipment.

## **1.10 Group – Advanced Surface Concepts**

This group of objects describe concepts applied to heat transfer surfaces that are of an advanced nature. Careful consideration must be given before using these.

### **1.10.1 SurfaceProperty:HeatTransferAlgorithm**

This object, and three other related objects, can be used to control which surface heat transfer model is used on specific surfaces. The separate object called HeatBalanceAlgorithm is used to control the heat transfer model in an overall way while this object can be used to revise the algorithm selections for specific surfaces. This object allows selectively overriding the global setting in HeatBalanceAlgorithm to choose one of the following models for a particular surface:

- CTF (Conduction Transfer Functions),
- EMPD (Effective Moisture Penetration Depth with Conduction Transfer Functions).
- CondFD (Conduction Finite Difference)
- HAMT (Combined Heat And Moisture Finite Element)

#### **1.10.1.1 Field: Surface Name**

This is the name of the surface that will be assigned to use the heat transfer algorithm selected in the next field. This should be a name of a surface defined elsewhere.

#### **1.10.1.2 Field: Algorithm**

This field is used to determine the heat transfer algorithm that is to be applied to the surface named in the previous field. The allowable choices are:

- ConductionTransferFunction
- MoisturePenetrationDepthConductionTransferFunction
- ConductionFiniteDifference
- CombinedHeatAndMoistureFiniteElement

### 1.10.2 SurfaceProperty:HeatTransferAlgorithm:MultipleSurface

This object can be used to control the surface heat transfer model used for specific types of surfaces. The separate object called HeatBalanceAlgorithm is used to control the heat transfer model in an overall way while this object can be used to revise the algorithm selections for specific types of surfaces. This object allows selectively overriding the global setting in HeatBalanceAlgorithm to choose one of the following models for all surfaces of a particular type:

- CTF (Conduction Transfer Functions),
- EMPD (Effective Moisture Penetration Depth with Conduction Transfer Functions).
- CondFD (Conduction Finite Difference)
- HAMT (Combined Heat And Moisture Finite Element)

#### 1.10.2.1 Field: Name

This is a unique, user-defined name for the object.

#### 1.10.2.2 Field: Surface Type

This field is selects the type of surfaces that are all assigned to use the heat transfer algorithm selected in the next field. This field is used with one of the following allowable keywords:

- AllExteriorSurfaces—all surfaces that have “Outdoors” outside boundary condition
- AllExteriorWalls—all walls that have “Outdoors” outside boundary condition
- AllExteriorRoofs—all roofs that have “Outdoors” outside boundary condition
- AllExteriorFloors—all floors that have “Outdoors” outside boundary condition
- AllGroundContactSurfaces—all surfaces that have “Ground” outside boundary condition
- AllInteriorSurfaces—all surfaces that are internal partition-type surfaces
- AllInteriorWalls—all walls that are internal surfaces
- AllInteriorCeilings—all ceilings that are internal surfaces
- AllInteriorFloors—all floors that are are internal surfaces

#### 1.10.2.3 Field: Algorithm

This field is used to determine the heat transfer algorithm that is to be applied to the surface types in the previous field. The allowable choices are:

- ConductionTransferFunction
- MoisturePenetrationDepthConductionTransferFunction
- ConductionFiniteDifference
- CombinedHeatAndMoistureFiniteElement

```
SurfaceProperty:HeatTransferAlgorithm:MultipleSurface,  
  my exterior wall override,  
  AllExteriorWalls,  
  ConductionFiniteDifference;
```

### 1.10.3 SurfaceProperty:HeatTransferAlgorithm:SurfaceList

This object can be used to control the surface heat transfer model used for a list of surfaces. The separate object called HeatBalanceAlgorithm is used to control the heat transfer model in an overall way while this object can be used to revise the algorithm selections for a list of specific surfaces. This object allows selectively overriding the global setting in HeatBalanceAlgorithm to choose one of the following models for listed:

- CTF (Conduction Transfer Functions),
- EMPD (Effective Moisture Penetration Depth with Conduction Transfer Functions).
- CondFD (Conduction Finite Difference)
- HAMT (Combined Heat And Moisture Finite Element)

#### 1.10.3.1 Field: Name

This is a unique, user-defined name for the object.

#### 1.10.3.2 Field: Algorithm

This field is used to determine the heat transfer algorithm that is to be applied to the surface listed in the remaining fields. The allowable choices are:

- ConductionTransferFunction
- MoisturePenetrationDepthConductionTransferFunction
- ConductionFiniteDifference
- CombinedHeatAndMoistureFiniteElement

#### 1.10.3.3 Field: Surface Name N

This is the name of the “Nth” surface that will be assigned to use the heat transfer algorithm selected in this object. These should be the names of surfaces defined elsewhere. This object is extensible. Additional surfaces can be added to extend the object.

An example IDF object follows.

```
SurfaceProperty:HeatTransferAlgorithm:SurfaceList,  
  my wall construct override,    !- Name  
  ConductionFiniteDifference,    !- Algorithm  
  Zn001:Wall1001,               !- Surface Name 1  
  Zn001:Wall1002,               !- Surface Name 2  
  Zn001:Wall1003,               !- Surface Name 3  
  Zn001:Wall1004,               !- Surface Name 4
```

#### 1.10.4 SurfaceProperty:HeatTransferAlgorithm:Construction

This object can be used to control the surface heat transfer model used for surfaces that have a specific type of construction. The separate object called HeatBalanceAlgorithm is used to control the heat transfer model in an overall way while this object can be used to revise the algorithm selections for specific constructions. This object allows selectively overriding the global setting in HeatBalanceAlgorithm to choose one of the following models for all surfaces with particular type of construction:

- CTF (Conduction Transfer Functions),
- EMPD (Effective Moisture Penetration Depth with Conduction Transfer Functions).
- CondFD (Conduction Finite Difference)
- HAMT (Combined Heat And Moisture Finite Element)

##### 1.10.4.1 Field: Name

This is a unique, user-defined name for the object.

##### 1.10.4.2 Field: Algorithm

This field is used to determine the heat transfer algorithm that is to be applied to the surfaces with the type of of construction listed in the next field. The allowable choices are:

- ConductionTransferFunction
- MoisturePenetrationDepthConductionTransferFunction
- ConductionFiniteDifference
- CombinedHeatAndMoistureFiniteElement

##### 1.10.4.3 Field: Construction Name

This field is the name of a Construction object defined elsewhere. All the surfaces in the model that are assigned this type of construction will be assigned to use the heat transfer algorithm selected in the previous field.

An example IDF object follows.

```
SurfaceProperty:HeatTransferAlgorithm:Construction,  
  my wall construct override,    !- Name  
  ConductionFiniteDifference,    !- Algorithm  
  R13WALL;                       !- Construction Name
```

### 1.10.5 SurfaceControl:MoveableInsulation

Movable insulation can be used/scheduled on any surface regular surface (such as a wall, floor, roof, etc.) but not on a subsurface (such as a window, use WindowProperty:ShadingControl instead). With movable insulation, no reference is made in the surface that is using the insulation – rather the movable insulation statement references the surface to which it is applied.

Exterior and interior movable insulation have undergone some testing and appears to producing expected results. The underlying principle has been implemented in EnergyPlus for both interior and exterior movable insulation with the possibility for exterior movable insulation to be transparent (transparent insulation material or TIM).

TIM exterior layers can be used with the ConductionFiniteDifference (CondFD) solution algorithm. With this addition, TIM layers can be used in conjunction with wall layers that have phase change materials (PCM) included, or any other advanced capability of the CondFD algorithm such as variable conductivity. The input requirements are exactly the same as when used with the CTF algorithm. The Solution Algorithm needs to be changed to CondFD, and as with CTF, the “SurfaceControl:MoveableInsulation” object must be completed to specify the insulated surface and the “WindowMaterial:Glazing” object is needed to provide the TIM layer properties.

Basically, the addition of movable insulation allows the user to schedule an extra amount of insulation on either the inside or outside surface of a wall (or both). The insulation must be a simple, homogenous material layer (linked to a material definition within the input data file). Note that EnergyPlus allows the exterior movable insulation layer to be transparent to short wavelength radiation (solar). In this case, incident solar is split between the plane between the movable insulation and the surface and the plane between the movable insulation and the surrounding air. This calculation is fairly basic and based on the solar transmittance of the insulation layer (material properties). Using transparent layers for exterior movable insulation allows solar energy to penetrate deeper into a construction where it can be stored for later use in the building (similar in concept to a Trombe Wall).

#### 1.10.5.1 Field: Insulation Type

This field determines whether the movable insulation is applied to the inside or the outside of the surface by entering either “Inside” or “Outside”, respectively.

#### 1.10.5.2 Field: Surface Name

This field refers the movable insulation back to a particular surface (ref: Building Surfaces) via its user assigned name so that EnergyPlus knows where to apply this extra layer of insulation. This will affect either the inside or outside surface heat balance of this surface depending on the value in the insulation type field (see previous field).

#### 1.10.5.3 Field: Material Name

This field refers to a material layer (e.g., Material, Material:NoMass, or WindowMaterial:Glazing; transparent layers are only valid for outside movable insulation) via its user assigned name. This provides the program with a full complement of material properties so that the effect of the insulation (R-value and solar transmittance) can be correctly taken into account by EnergyPlus.

#### 1.10.5.4 Field: Schedule Name

This field is a schedule that theoretically can be any positive real number but was originally intended to be a parameter between 0.0 and 1.0. Its purpose is to act as a fractional modifier on the resistance of the material layer. The actual thermal resistance of the movable insulation is equal to the resistance of the material layer times the current value in the movable insulation schedule. A value of 0.0 simply means that the movable insulation is not present.

An example of this syntax implemented in an input file is:

```
SurfaceControl:MoveableInsulation,  
  Exterior,                               ! Insulation Type  
  Zone001:Wall001,                         ! Surface Name  
  TransparentInsulationMaterial,           ! Material Name  
  PresentInWinterSchedule,                 ! Schedule Name
```

### 1.10.6 SurfaceProperty:OtherSideCoefficients

By referencing the Other Side Coefficients statement in the surface statements (i.e. Outside Boundary Condition), the temperature of the outer plane of a surface (see Figure 41) can be directly controlled. Other side coefficients can also be used to control the exterior convective heat transfer coefficient of a surface and the corresponding exterior air temperature. It should be noted that solar effects are not accounted for when other side coefficients are used. In addition, if other side coefficients are specified for a surface, they also hold for subsurfaces of that surface (though subsurfaces can have their own coefficient set).

Other side coefficients have the same effect on all types of heat transfer surfaces. In other words, an interior surface with other side coefficients specified and an exterior wall with identical other side coefficients specified are simulated exactly the same. A surface that uses other side coefficients should be thought of as a new or separate type of surface. All heat transfer surfaces are simulated in the same manner through conduction transfer functions. The only difference between the various types of heat transfer surfaces is the environment on the other side of the surface. For example, the other side environment of an exterior surface is the outdoor environment. For an interior surface, the temperature of the outer plane of the surface is set equal to the temperature of the inner plane of the surface. Similarly, a surface with other side coefficients specified will allow the user to control the other side environment.

Heat transfer through a surface is an extremely important component in the calculation of zone loads. The information to calculate this heat transfer is readily

available if the surface is exposed to the outdoor environment or to another zone that is being simulated. Occasionally, a user will want to model the heat transfer through a surface that is adjacent to an area that is not included in the EnergyPlus model. For example, an office area is attached to a warehouse and the user is only interested in simulating the office area. An interior surface with other side coefficients specified could be used to control the environment on the other side of the surface, thereby accounting for the heat transfer through the adjoining surface.

Other Side Coefficients affects the "other side" of a surface as described below. Each coefficient has a special meaning. You may enter a 0 or blank if you are not using a particular coefficient. Note that there are two potential ways to use other side coefficients. Either they are used to set the temperature of the exterior side surface directly (if the combined convective/radiative coefficient below is less than or equal to zero) or to set both the film coefficient (positive value for the combined convective/radiative coefficient below) and the outside air temperature.

#### **1.10.6.1 Field: Name**

This, of course, is the string referenced in the Surface statement that is using OtherSideCoefficients as the Outside Boundary Condition.

#### **1.10.6.2 Field: Combined Convective/Radiative Film Coefficient**

This is a trigger value. If the value is greater than zero, then it is taken to be the combined convective/radiative film coefficient. In this case (value > 0), the remaining fields are used first to calculate the outside air temperature for the surface and then to calculate the outside surface temperature based on the outside air temperature and the film coefficient. If this field is less than or equal to zero, then the remaining fields are used to calculate the surface temperature (not the outside air temperature). The units for this field are the same as for a convective heat transfer coefficient:  $W/(m^2 \cdot K)$ . This is referred to as "C1" in the reference below.

#### **1.10.6.3 Field: Constant Temperature**

This field defines a temperature term that is a constant part of the calculation either of the surface or outside air temperature. This parameter is shown as "C2" in the equation below. The units for this parameter are degrees C. If a schedule name is included as the second parameter, the value of this parameter will be overridden by the value from the schedule. The default for this field is 0.0.

#### **1.10.6.4 Field: Constant Temperature Coefficient**

This field defines a constant coefficient that is applied to the constant temperature (see previous field). This parameter is shown as "C3" in the equation below. This parameter is dimensionless. The value of this parameter is usually 1.0 if a schedule is used to set C2. This field is ignored if *Sinusoidal Variation of Constant Temperature Coefficient* = Yes. The default for this field is 1.0.

#### **1.10.6.5 Field: External Dry-Bulb Temperature Coefficient**

This field defines a constant coefficient that is applied to the outside air dry-bulb temperature. This parameter is shown as "C4" in the equation below. This parameter is dimensionless. The default for this field is 0.0.

#### **1.10.6.6 Field: Ground Temperature Coefficient**

This field defines a constant coefficient that is applied to the ground temperature (ref. Site:GroundTemperature:BuildingSurface). This parameter is shown as "C5" in the equation below. This parameter is dimensionless.

#### **1.10.6.7 Field: Wind Speed Coefficient**

This field defines a constant coefficient that is applied to the product of the outside air dry-bulb temperature and the wind speed. This parameter is shown as "C6" in the equation below. This parameter has dimensions of inverse velocity or s/m. The default for this field is 0.0.

#### **1.10.6.8 Field: Zone Air Temperature Coefficient**

This field defines a constant coefficient that is applied to the temperature of the zone to which this surface belongs. This parameter is shown as "C7" in the equation below. This parameter is dimensionless. The default for this field is 0.0.

#### **1.10.6.9 Field: Constant Temperature Schedule Name**

This field is used to supply a schedule name. That schedule will supply the "constant" temperature value C2. Note that the value of the C3 field should normally be 1.0 if a schedule is used for C2. If not blank, this field must be a valid schedule name.

#### **1.10.6.10 Field: Sinusoidal Variation of Constant Temperature Coefficient**

This field is optional and can be used to define an alternate method of prescribing the coefficient that is applied to the constant temperature (see the fields Constant Temperature and Constant Temperature Coefficient). This parameter is shown as "C2" in the equation below. If this field is omitted, left blank, or set to "No," then C2 is a constant (defined in the field Constant Temperature Coefficient). However if this is set to "Yes," then the value of C2 varies with a unitary sine wave in the following way:

$$C2 = \text{Sin} \left( 2\pi \frac{(\text{time of day})}{(\text{period})} \right) \quad (17)$$

The value for “period” is controlled in the following field. The value for “time of day” is based on the zone timestep and is in units of hours. The sine function here uses input as radians. When using this option, the value for C2 will vary between -1.0 and 1.0 and the value put in the field Constant Temperature Coefficient is not used. This option cannot be used at the same time as scheduling a constant temperature with the previous field.

#### 1.10.6.11 Field: Period of Sinusoidal Variation

This field is used to define the period of the sine wave when using the Sinusoidal Variation of Constant Temperature Coefficient capability selected in the previous field. This field is the time period of the sine wave in units of hours. The default is 24 hours and provides a diurnal sine wave. The value entered here is “period” in the equation in the previous field.

#### 1.10.6.12 Field: Previous Other Side Temperature Coefficient

This field defines a constant coefficient that is applied to the other side temperature computed by this object from the previous zone time step. This parameter is shown as “C8” in the equation below. This parameter is dimensionless. The default for this field is 0.0.

#### 1.10.6.13 Field: Minimum Other Side Temperature Limit

This field specifies a lower limit for the other side temperature result in degrees C. If blank, there is no lower limit.

#### 1.10.6.14 Field: Maximum Other Side Temperature Limit

This field specifies an upper limit for the other side temperature result in degrees C. If blank, there is no upper limit.

The coefficients listed above are used in the following equation:

$$T = C2 * C3 + C4 * T_{oadb} + C5 * T_{grnd} + C6 * W_{spd} * T_{oadb} + C7 * T_{zone} + C8 * T_{past} \quad (18)$$

where:

T = Outside Air Temperature when C1 (Combined convective/radiative film Coeff) > 0

T = Exterior Surface Temperature when C1 (Combined convective/radiative film Coeff) <= 0

Tzone = Temperature of the zone being simulated (°C)

Toadb = Dry-bulb temperature of the outdoor air (°C)

Tgrnd = Temperature of the ground (°C) from Site:GroundTemperature:BuildingSurface

Wspd = Outdoor wind speed (m/sec)

Tpast = Other side temperature from previous zone timestep (°C)

### 1.10.7 SurfaceProperty:OtherSideCoefficients Outputs

Zone,Average,Surface Other Side Coefficients Exterior Air Drybulb Temperature

#### 1.10.7.1 Surface Other Side Coefficients Exterior Air Drybulb Temperature [C]

This is the air temperature applied to the other side of the surface.

### 1.10.8 SurfaceProperty:OtherSideConditionsModel

By referencing the Other Side Conditions Model statement in the surface statements (i.e. Outside Boundary Condition), the boundary conditions for the outer plane of the mass wall can be connected to the appropriate model for various multi-skin components. The types of multi-skin components that use this object include systems that are mounted to the outside surface using standoffs that create a small air gap – see Figure 42. This type of modeling allows using the usual heat transfer calculations for the underlying surface with other types of multi-skin component models that are available including: unglazed transpired solar collectors, ventilated photovoltaic panels, and naturally ventilated facades.

The boundary condition values are determined dynamically by the program using internal component models. If you want to define other side surface temperatures or convection conditions, then use SurfaceProperty:OtherSideCoefficients instead of this object.

It should be noted that when other side conditions models are used, solar effects are removed from the surface's outside face heat balance, but are used in modeling the component adjacent to that surface.

In addition, the other side conditions model has been modified to include underground piping system interaction. The PipingSystem:Underground:Domain object represents a mass of ground which may include interaction with, for example, basement surfaces. In this case, the ground model will internally use the other side condition model hook to update boundary conditions for those surfaces which use that other side condition model name reference.

#### 1.10.8.1 Field: Name

This is the string referenced in the Surface statement that is using OtherSideModel as the Exterior Environment.

#### 1.10.8.2 Field: Type of Modeling

This is a string key selection used to identify the type of model that will be used to determine boundary conditions. The only available choices are "GapConvectionRadiation" or "UndergroundPipingSystemSurface."

Figure 42. Illustration for Other Side Conditions Model

An example specification is:

### 1.10.9 SurfaceProperty:OtherSideConditionsModel Outputs

- Zone,Average,Surface Other Side Conditions Modeled Convection Air Temperature [C]
- Zone,Average,Surface Other Side Conditions Modeled Convection Heat Transfer Coefficient [W/m2-K]
- Zone,Average,Surface Other Side Conditions Modeled Radiation Temperature [C]
- Zone,Average,Surface Other Side Conditions Modeled Radiation Heat Transfer Coefficient [W/m2-K]

#### 1.10.9.1 Surface Other Side Conditions Modeled Convection Air Temperature [C]

This is the air temperature exposed to the other side of the surface by the model and used in convection heat transfer calculations.

#### 1.10.9.2 Surface Other Side Conditions Modeled Convection Heat Transfer Coefficient [W/m2-K]

This is the surface convection heat transfer coefficient applied to the other side of the surface by the model.

#### 1.10.9.3 Surface Other Side Conditions Modeled Radiation Temperature [C]

This is the effective temperature exposed to the other side of the surface for thermal radiation heat transfer calculations.

#### 1.10.9.4 Surface Other Side Conditions Modeled Radiation Heat Transfer Coefficient [W/m2-K]

This is the effective (linearized) radiation heat transfer coefficient applied to the other side of the surface by the model.

### 1.10.10 SurfaceConvectionAlgorithm:Inside:AdaptiveModelSelections

This object provides options to change the individual convection model equations for dynamic selection when using AdaptiveConvectionAlgorithm. This object is only needed to make changes to the default model selections for any or all of the surface categories. This object is for the inside face, the side of the surface facing a thermal zone.

#### 1.10.10.1 Field: Name

A unique name for the object.

#### 1.10.10.2 Field: Simple Buoyancy Vertical Wall Equation Source

Applies to zone with no HVAC or when HVAC is off. This is for vertical walls. The key choice options include: FohannoPolidoriVerticalWall, ASHRAEVerticalWall, AlamdariHammondVerticalWall, KhalifaEq3WallAwayFromHeat, KhalifaEq6NonHeatedWalls FohannoPolidoriVerticalWall, ISO15099Windows, or UserCurve

#### 1.10.10.3 Field: Simple Buoyancy Vertical Wall User Curve Name

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

#### 1.10.10.4 Field: Simple Buoyancy Stable Horizontal Equation Source

Applies to zone with no HVAC or when HVAC is off. This is for horizontal surfaces with heat flow directed for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve

#### 1.10.10.5 Field: Simple Buoyancy Stable Horizontal Equation User Curve Name

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

#### 1.10.10.6 Field: Simple Buoyancy Unstable Horizontal Equation Source

Applies to zone with no HVAC or when HVAC is off. This is for passive horizontal surfaces with heat flow for unstable thermal stratification. The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, or UserCurve.

#### 1.10.10.7 Field: Simple Buoyancy Unstable Horizontal Equation User Curve Name

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.8 Field: Simple Buoyancy Stable Tilted Equation Source**

Applies to zone with no HVAC or when HVAC is off. This is for tilted surfaces with heat flow for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve

#### **1.10.10.9 Field: Simple Buoyancy Stable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.10 Field: Simple Buoyancy Unstable Tilted Equation Source**

Applies to zone with no HVAC or when HVAC is off. This is for tilted surfaces with heat flow for unstable thermal stratification. The key choices include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, or UserCurve.

#### **1.10.10.11 Field: Simple Buoyancy Unstable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.12 Field: Simple Buoyancy Windows Equation Source**

Applies to zone with no HVAC or when HVAC is off. This is for all window surfaces. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, FohannoPolidoriVerticalWall, KaradagChilledCeiling, ISO15099Windows, or UserCurve.

#### **1.10.10.13 Field: Simple Buoyancy Windows Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.14 Field: Floor Heat Ceiling Cool Vertical Wall Equation Source**

Applies to zone with in-floor heating and/or in-ceiling cooling. This is for vertical walls. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, KhalifaEq3WallAwayFromHeat, FohannoPolidoriVerticalWall, ISO15099Windows, or UserCurve.

#### **1.10.10.15 Field: Floor Heat Ceiling Cool Vertical Wall Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.16 Field: Floor Heat Ceiling Cool Stable Horizontal Equation Source**

Applies to zone with in-floor heating and/or in-ceiling cooling. This is for passive horizontal surfaces with heat flow for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve.

#### **1.10.10.17 Field: Floor Heat Ceiling Cool Stable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.18 Field: Floor Heat Ceiling Cool Unstable Horizontal Equation Source**

Applies to zone with in-floor heating and/or in-ceiling cooling. This is for passive horizontal surfaces with heat flow for unstable thermal stratification. The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, KhalifaEq4CeilingAwayFromHeat, or UserCurve.

#### **1.10.10.19 Field: Floor Heat Ceiling Cool Unstable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.20 Field: Floor Heat Ceiling Cool Heated Floor Equation Source**

Applies to zone with in-floor heating and/or in-ceiling cooling. This is for a floor with active heating elements. The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, AwbiHattonHeatedFloor, or UserCurve

#### **1.10.10.21 Field: Floor Heat Ceiling Cool Heated Floor Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.22 Field: Floor Heat Ceiling Cool Chilled Ceiling Equation Source**

Applies to zone with in-floor heating and/or in-ceiling cooling. This is for a ceiling with active cooling elements. The key choice options include:

WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, KaradagChilledCeiling, or UserCurve.

**1.10.10.23 Field: Floor Heat Ceiling Cool Chilled Ceiling Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

**1.10.10.24 Field: Floor Heat Ceiling Cool Stable Tilted Equation Source**

Applies to zone with in-floor heating and/or in-ceiling cooling. This is for tilted surfaces with heat flow for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, ISO15099Windows, or UserCurve.

**1.10.10.25 Field: Floor Heat Ceiling Cool Stable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.10.10.26 Field: Floor Heat Ceiling Cool Unstable Tilted Equation Source**

Applies to zone with in-floor heating and/or in-ceiling cooling. This is for tilted surfaces with heat flow for unstable thermal stratification. The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, ISO15099Windows, or UserCurve.

**1.10.10.27 Field: Floor Heat Ceiling Cool Unstable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.10.10.28 Field: Floor Heat Ceiling Cool Window Equation Source**

Applies to zone with in-floor heating and/or in-ceiling cooling. This is for all window surfaces. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, ISO15099Windows, or UserCurve.

**1.10.10.29 Field: Floor Heat Ceiling Cool Window Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.10.10.30 Field: Wall Panel Heating Vertical Wall Equation Source**

Applies to zone with in-wall panel heating. This is for vertical walls that are not actively heated. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, KhalifaEq6NonHeatedWalls, FohannoPolidoriVerticalWall, AlamdariHammondVerticalWall, ISO15099Windows, or UserCurve.

**1.10.10.31 Field: Wall Panel Heating Vertical Wall Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.10.10.32 Field: Wall Panel Heating Heated Wall Equation Source**

Applies to zone with in-wall panel heating. This is for vertical walls that are being actively heated. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, KhalifaEq5WallNearHeat, AwbiHattonHeatedWall, FohannoPolidoriVerticalWall, AlamdariHammondVerticalWall, or UserCurve.

**1.10.10.33 Field: Wall Panel Heating Heated Wall Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.10.10.34 Field: Wall Panel Heating Stable Horizontal Equation Source**

Applies to zone with in-wall panel heating. This is for horizontal surfaces with heat flow directed for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve.

**1.10.10.35 Field: Wall Panel Heating Stable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.10.10.36 Field: Wall Panel Heating Unstable Horizontal Equation Source**

Applies to zone with in-wall panel heating. This is for horizontal surfaces with heat flow directed for unstable thermal stratification. The key choice options include: ASHRAEVerticalWall, WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, KhalifaEq7Ceiling, or UserCurve

**1.10.10.37 Field: Wall Panel Heating Unstable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.38 Field: Wall Panel Heating Stable Tilted Equation Source**

Applies to zone with in-wall panel heating. This is for tilted surfaces with heat flow for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, ISO15099Windows, or UserCurve.

#### **1.10.10.39 Field: Wall Panel Heating Stable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

#### **1.10.10.40 Field: Wall Panel Heating Unstable Tilted Equation Source**

Applies to zone with in-wall panel heating. This is for tilted surfaces with heat flow for unstable thermal stratification. The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, ISO15099Windows, or UserCurve.

#### **1.10.10.41 Field: Wall Panel Heating Unstable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.42 Field: Wall Panel Heating Window Equation Source**

Applies to zone with in-wall panel heating. This is for all window surfaces. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, FohannoPolidoriVerticalWall, ISO15099Windows, or UserCurve.

#### **1.10.10.43 Field: Wall Panel Heating Window Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.44 Field: Convective Zone Heater Vertical Wall Equation Source**

Applies to zone with convective heater. This is for vertical walls not directly affected by heater. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, KhalifaEq3WallAwayFromHeat, KhalifaEq6NonHeatedWalls, FohannoPolidoriVerticalWall, ISO15099Windows, or UserCurve

#### **1.10.10.45 Field: Convective Zone Heater Vertical Wall Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.46 Field: Convective Zone Heater Vertical Walls Near Heater Equation Source**

Applies to zone with convective heater. This is for vertical walls that are directly affected by heater. Walls are considered "near" when listed in field set for Fraction of Radiant Energy to Surface. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, KhalifaEq5WallNearHeat, AwbiHattonHeatedWall, FohannoPolidoriVerticalWall, ISO15099Windows, or UserCurve.

#### **1.10.10.47 Field: Convective Zone Heater Vertical Walls Near Heater Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.48 Field: Convective Zone Heater Stable Horizontal Equation Source**

Applies to zone with convective heater. This is for horizontal surfaces with heat flow directed for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve.

#### **1.10.10.49 Field: Convective Zone Heater Stable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

#### **1.10.10.50 Field: Convective Zone Heater Unstable Horizontal Equation Source**

Applies to zone with convective heater. This is for horizontal surfaces with heat flow directed for unstable thermal stratification. The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, KhalifaEq4CeilingAwayFromHeat, KhalifaEq7Ceiling, or UserCurve.

#### **1.10.10.51 Field: Convective Zone Heater Unstable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.52 Field: Convective Zone Heater Stable Tilted Equation Source**

Applies to zone with convective heater. This is for tilted surfaces with heat flow for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve.

**1.10.10.53 Field: Convective Zone Heater Stable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.10.10.54 Field: Convective Zone Heater Unstable Tilted Equation Source**

Applies to zone with convective heater. This is for tilted surfaces with heat flow for unstable thermal stratification. The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, or UserCurve.

**1.10.10.55 Field: Convective Zone Heater Unstable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.10.10.56 Field: Convective Zone Heater Windows Equation Source**

Applies to zone with convective heater. This is for all window surfaces. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, KhalifaEq3WallAwayFromHeat, FohannoPolidoriVerticalWall, ISO15099Windows, or UserCurve.

**1.10.10.57 Field: Convective Zone Heater Windows Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.10.10.58 Field: Central Air Diffuser Wall Equation Source**

Applies to zone with mechanical forced central air with diffusers. This is for all wall surfaces. The key choice options include: ASHRAEVerticalWall, FisherPedersenCeilingDiffuserWalls, AlamdariHammondVerticalWall, BeausoleilMorrisonMixedAssistedWall, BeausoleilMorrisonMixedOpposingWall, FohannoPolidoriVerticalWall, ISO15099Windows, GoldsteinNovoselacCeilingDiffuserWalls, or UserCurve

**1.10.10.59 Field: Central Air Diffuser Wall Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.10.10.60 Field: Central Air Diffuser Ceiling Equation Source**

Applies to zone with mechanical forced central air with diffusers. This is for all ceiling surfaces. The key choice options include: FisherPedersenCeilingDiffuserCeiling, BeausoleilMorrisonMixedStableCeiling, BeausoleilMorrisonMixedUnstableCeiling, or UserCurve.

**1.10.10.61 Field: Central Air Diffuser Ceiling Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.10.10.62 Field: Central Air Diffuser Floor Equation Source**

Applies to zone with mechanical forced central air with diffusers. This is for all floor surfaces. The key choice options include: FisherPedersenCeilingDiffuserFloor, BeausoleilMorrisonMixedStableFloor, BeausoleilMorrisonMixedUnstableFloor, GoldsteinNovoselacCeilingDiffuserFloor, or UserCurve.

**1.10.10.63 Field: Central Air Diffuser Floor Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.10.10.64 Field: Central Air Diffuser Window Equation Source**

Applies to zone with mechanical forced central air with diffusers. This is for all window surfaces. The key choice options include: ASHRAEVerticalWall, FisherPedersenCeilingDiffuserWalls, BeausoleilMorrisonMixedAssistedWall, BeausoleilMorrisonMixedOpposingWall, FohannoPolidoriVerticalWall, AlamdariHammondVerticalWall, ISO15099Windows, GoldsteinNovoselacCeilingDiffuserWindow, or UserCurve.

**1.10.10.65 Field: Central Air Diffuser Window Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

**1.10.10.66 Field: Mechanical Zone Fan Circulation Vertical Wall Equation Source**

The key choice options include: KhalifaEq3WallAwayFromHeat, ASHRAEVerticalWall, FisherPedersenCeilingDiffuserWalls, AlamdariHammondVerticalWall, BeausoleilMorrisonMixedAssistedWall, BeausoleilMorrisonMixedOpposingWall, FohannoPolidoriVerticalWall, ISO15099Windows, GoldsteinNovoselacCeilingDiffuserWalls, or UserCurve.

**1.10.10.67 Field: Mechanical Zone Fan Circulation Vertical Wall Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

**1.10.10.68 Field: Mechanical Zone Fan Circulation Stable Horizontal Equation Source**

The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve.

**1.10.10.69 Field: Mechanical Zone Fan Circulation Stable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.10.10.70 Field: Mechanical Zone Fan Circulation Unstable Horizontal Equation Source**

The key choice options include: KhalifaEq4CeilingAwayFromHeat, WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, or UserCurve.

**1.10.10.71 Field: Mechanical Zone Fan Circulation Unstable Horizontal Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.10.10.72 Field: Mechanical Zone Fan Circulation Stable Tilted Equation Source**

The key choice options include: WaltonStableHorizontalOrTilt or UserCurve

**1.10.10.73 Field Mechanical Zone Fan Circulation Stable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.10.10.74 Field: Mechanical Zone Fan Circulation Unstable Tilted Equation Source**

The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, or UserCurve.

**1.10.10.75 Field: Mechanical Zone Fan Circulation Unstable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.10.10.76 Field: Mechanical Zone Fan Circulation Window Equation Source**

The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, FohannoPolidoriVerticalWall, ISO15099Windows, GoldsteinNovoselacCeilingDiffuserWindow, or UserCurve.

**1.10.10.77 Field: Mechanical Zone Fan Circulation Unstable Tilted Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

**1.10.10.78 Field: Mixed Regime Buoyancy Assisting Flow on Walls Equation Source**

The key choice options include: BeausoleilMorrisonMixedAssistedWall, AlamdariHammondVerticalWall, FohannoPolidoriVerticalWall, ASHRAEVerticalWall, FisherPedersenCeilingDiffuserWalls, GoldsteinNovoselacCeilingDiffuserWalls, or UserCurve.

**1.10.10.79 Field: Mixed Regime Buoyancy Assisting Flow on Walls Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

**1.10.10.80 Field: Mixed Regime Buoyancy Opposing Flow on Walls Equation Source**

The key choice options include: BeausoleilMorrisonMixedOpposingWall, AlamdariHammondVerticalWall, FohannoPolidoriVerticalWall, ASHRAEVerticalWall, FisherPedersenCeilingDiffuserWalls, GoldsteinNovoselacCeilingDiffuserWalls, or UserCurve

**1.10.10.81 Field: Mixed Regime Buoyancy Opposing Flow on Walls Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve

**1.10.10.82 Field: Mixed Regime Stable Floor Equation Source**

The key choice options include: BeausoleilMorrisonMixedStableFloor, WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve

**1.10.10.83 Field: Mixed Regime Stable Floor Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.84 Field: Mixed Regime Unstable Floor Equation Source**

The key choice options include: BeausoleilMorrisonMixedUnstableFloor, WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, or UserCurve.

#### **1.10.10.85 Field: Mixed Regime Unstable Floor Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.86 Field: Mixed Regime Stable Ceiling Equation Source**

The key choice options include: BeausoleilMorrisonMixedStableCeiling, WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, or UserCurve.

#### **1.10.10.87 Field: Mixed Regime Stable Ceiling Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.88 Field: Mixed Regime Unstable Ceiling Equation Source**

The key choice options include: BeausoleilMorrisonMixedUnstableCeiling, WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, or UserCurve.

#### **1.10.10.89 Field: Mixed Regime Unstable Ceiling Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.10.90 Field: Mixed Regime Window Equation Source**

The key choice options include: GoldsteinNovoselacCeilingDiffuserWindow, ISO15099Windows, or UserCurve.

#### **1.10.10.91 Field: Mixed Regime Window Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

### **1.10.11 SurfaceConvectionAlgorithm:Outside:AdaptiveModelSelections**

Options to change the individual convection model equations for dynamic selection when using AdaptiveConvectionAlgorithm. This object is only needed to make changes to the default model selections for any or all of the surface categories. This object is for the outside face, the side of the surface facing away from the thermal zone.

#### **1.10.11.1 Field: Name**

A unique name for the object

#### **1.10.11.2 Field: Wind Convection Windward Vertical Wall Equation Source**

This is for just the wind-driven component of the total convection coefficient. The key choice options include: SimpleCombined, TARPWindward, MoWiTTWindward, DOE2Windward, NusseltJurges, McAdams, Mitchell, Blocken, Emmel, or UserCurve.

#### **1.10.11.3 Field: Wind Convection Windward Equation Vertical Wall User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.11.4 Field: Wind Convection Leeward Vertical Wall Equation Source**

This is for just the wind-driven component of the total convection coefficient. The key choice options include: SimpleCombined, TARPLEeward, MoWiTTLeeward, DOE2Leeward, Emmel, NusseltJurges, McAdams, Mitchell, or UserCurve.

#### **1.10.11.5 Field: Wind Convection Leeward Vertical Wall Equation User Curve Name**

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### **1.10.11.6 Field: Wind Convection Horizontal Roof Equation Source**

This is for just the wind-driven component of the total convection coefficient. The key choice options include: SimpleCombined, TARPWindward, MoWiTTWindward, DOE2Windward, NusseltJurges, McAdams, Mitchell, Blocken, Emmel, ClearRoof, or UserCurve.

#### 1.10.11.7 Field: Wind Convection Horizontal Roof User Curve Name

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### 1.10.11.8 Field: Natural Convection Vertical Wall Equation Source

This is for just the natural convection portion of the total film coefficient. This is for vertical walls. The key choice options include: ASHRAEVerticalWall, AlamdariHammondVerticalWall, FohannoPolidoriVerticalWall, ISO15099Windows, UserCurve, or None.

#### 1.10.11.9 Field: Natural Convection Vertical Wall Equation User Curve Name

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### 1.10.11.10 Field: Natural Convection Stable Horizontal Equation Source

This is for just the natural convection portion of the total film coefficient. This is for horizontal surfaces with heat flow directed for stable thermal stratification. The key choice options include: WaltonStableHorizontalOrTilt, AlamdariHammondStableHorizontal, UserCurve, or None.

#### 1.10.11.11 Field: Natural Convection Stable Horizontal Equation User Curve Name

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

#### 1.10.11.12 Field: Natural Convection Unstable Horizontal Equation Source

This is for just the natural convection portion of the total film coefficient. This is for horizontal surfaces with heat flow directed for unstable thermal stratification. The key choice options include: WaltonUnstableHorizontalOrTilt, AlamdariHammondUnstableHorizontal, UserCurve, or None.

#### 1.10.11.13 Field: Natural Convection Unstable Horizontal Equation User Curve Name

The SurfaceConvectionAlgorithm:UserCurve named in this field is used when the previous field is set to UserCurve.

### 1.10.12 SurfaceConvectionAlgorithm:Inside:UserCurve

This object is used to describe a custom model equation for surface convection heat transfer coefficients. If more than one curve is referenced, or non-blank, then they are all used and the result is the simple addition of all the curve results.

#### 1.10.12.1 Field: Name

Unique name of input object.

#### 1.10.12.2 Field: Reference Temperature for Convection Heat Transfer

This field controls the nature of the reference temperature used with convection coefficient when calculating the heat flow at the surface. Select one of the three choices: MeanAirTemperature, AdjacentAirTemperature, SupplyAirTemperature. MeanAirTemperature is the typical application for the classic convection model used with the complete mixing of room air. AdjacentAirTemperature applies when used with Roomair models that account for temperature variations within the zone air and directs the model to use the temperature near the surface rather than the average for the entire zone. SupplyAirTemperature directs the model to use the supply air conditions for the heat transfer conditions.

#### 1.10.12.3 Field: Hc Function of Temperature Difference Curve Name

This field contains the name of separate performance curve or table object that describes  $h_c$ , the convection coefficient, as a function of temperature difference. The curve's "x" is absolute value of delta-T (Surface temperature minus air temperature, (C))

#### 1.10.12.4 Field: Hc Function of Temperature Difference Divided by Height Curve Name

This field contains the name of separate performance curve or table object that describes  $h_c$ , the convection coefficient, as a function of temperature difference divided by height. The curve's "x" is absolute value of delta-T/Height (Surface temp minus Air temp)/(vertical length scale), (C/m). For an inside face, the vertical length scale is the zone's interior height.

#### 1.10.12.5 Field: Hc Function of Air Change Rate Curve Name

This field contains the name of separate performance curve or table object that describes  $h_c$ , the convection coefficient, as a function of air change rate. The curve's "x" is mechanical ACH (Air Changes per hour from mechanical air system), (1/hr)

#### 1.10.12.6 Field: Hc Function of Air System Volume Flow Rate Divided by Zone Perimeter Length Curve Name

This field contains the name of separate performance curve or table object that describes  $h_c$ , the convection coefficient, as a function of air change rate divided

perimeter scale. Curve's "x" is mechanical system air flow rate (m<sup>3</sup>/s) divided by zone's length along exterior walls (m).

### 1.10.13 SurfaceConvectionAlgorithm:Outside:UserCurve

This object is used to describe a custom model equation for surface convection heat transfer coefficients. If more than one curve is referenced, or non-blank, then they are all used and the result is the simple addition of all the curve results.

#### 1.10.13.1 Field: Name

Unique name of input object.

#### 1.10.13.2 Field: Wind Speed Type for Curve

This field specifies what sort of wind velocity data should be used in when evaluating the curve in the following field. There are for key choice options. "WeatherFile" directs using the unmodified value from the epw file or design weather data. "HeightAdjust" uses the value from the epw file modified for height above ground, as determined by the z coordinate, using the site terrain and weather station information. "ParallelComponent" uses the value from the epw file modified to take just the velocity component that is parallel to the surface. "ParallelComponentHeightAdjust" uses the height adjusted wind velocity and then computes the parallel component.

#### 1.10.13.3 Field: Hf Function of Wind Speed Curve Name

This field contains the name of separate performance curve or table object that describes  $h_f$ , the forced convection coefficient, as a function of wind speed. The curve's "x" is wind speed as defined by the method chosen in the previous field.

#### 1.10.13.4 Field: Hn Function of Temperature Difference Curve Name

This field contains the name of separate performance curve or table object that describes  $h_n$ , the natural convection coefficient, as a function of temperature difference. Curve's "x" is absolute value of delta-T (Surface temperature minus air temperature, (C))

#### 1.10.13.5 Field: Hc Function of Temperature Difference Divided by Height Curve Name

This field contains the name of separate performance curve or table object that describes  $h_n$ , the natural convection coefficient, as a function of temperature difference divided by height. Curve's "x" is absolute value of delta-T/Height (Surface temp minus Air temp)/(vertical length scale), (C/m). For an outside face the vertical length scale is the exterior facade's overall height.

### 1.10.14 SurfaceProperty:ConvectionCoefficients

The convection coefficients of each surface, both exterior and interior, are automatically calculated during EnergyPlus execution. These calculations are "governed" by other objects such as the SurfaceConvectionAlgorithm:Inside (overall default), the Zone object's field called Zone Inside Convection Algorithm (Zone Default), the and the SurfaceConvectionAlgorithm:Outside (overall default), and/or the Zone object's field called Zone Outside Convection Algorithm (Zone Default). Usually, that will be enough flexibility for most users. However, if you need to match pre-existing convection coefficients (from another program) or are trying to match a test suite of results, you may wish to use the "override" convection coefficients in the following object. This object allows for a single surface to be given specific convection coefficients.

Note that using these in conjunction, in particular, the "Simple" option on either the Outside Convection Algorithm or the Zone Outside Convection Algorithm field will result in a combined coefficient regardless of choice chosen here.

Note that surfaces with "SurfaceProperty:OtherSideCoefficients" cannot use this object with the "outside" coefficient – attempting to do so will cause a severe error; SurfaceProperty:OtherSideCoefficients surfaces can apply an "inside" coefficient. And, surfaces with "Ground" exposure do not use the "outside" coefficient that might be supplied here. Note, too, that some lower boundaries are used regardless by certain surface types (i.e. Window) or certain algorithm types.

#### 1.10.14.1 Field: Surface Name

This field is the applicable surface name for the user supplied convection coefficient.

#### 1.10.14.2 Fields (Convection Location, Type, Coefficient & Schedule Name)

For simplicity, the descriptions of these field occur together – however, the fields are used sequentially when put into the IDF file (reference the IDF examples following the descriptions).

#### 1.10.14.3 Field: Convection Coefficient 1 Location

#### 1.10.14.4 Field: Convection Coefficient 2 Location

This field contains the word "Outside" or "Inside" depending on which location is being described.

#### 1.10.14.5 Field: Convection Coefficient 1 Type

#### 1.10.14.6 Field: Convection Coefficient 2 Type

The entries can be of several types: Value (simple numeric value), Schedule (name of schedule with the values), the usual key choices for overall models for Outside or Inside (Simple, SimpleCombined, TARP, AdaptiveConvectionAlgorithm etc.), the key choices for individual convection equations used for customizing the adaptive algorithm, or a custom user defined correlation. The field should contain one of the keys listed in the table below along with face they can be applied. The definitions of the models and key choices are discussed under SurfaceConvectionAlgorithm:Inside, SurfaceConvectionAlgorithm:Outside, SurfaceConvectionAlgorithm:Inside:AdaptiveModelSelections, and SurfaceConvectionAlgorithm:Outside:AdaptiveModelSelections.

Key choice	Applies to Inside or Outside
Value	Both
Schedule	Both
Simple	Inside
SimpleCombined	Outside
TARP	Both
DOE-2	Outside
MoWitt	Outside
AdaptiveConvectionAlgorithm	Both
ASHRAEVerticalWall	Both
WaltonUnstableHorizontalOrTilt	Both

UserCurve	Both

#### 1.10.14.7 Field: Convection Coefficient 1

#### 1.10.14.8 Field: Convection Coefficient 2

If the Convection type was "Value", then this field is filled and contains the simple value to be used. Otherwise, this can be blank.

#### 1.10.14.9 Field: Convection Coefficient 1 Schedule Name

#### 1.10.14.10 Field: Convection Coefficient 2 Schedule Name

If the Convection type was "Schedule", then this field contains the name of a schedule describing the value to be used during the time intervals for the schedule.

The complete IDD definition for the ConvectionCoefficients object follows:

#### 1.10.14.11 Field: Convection Coefficient 1 User Curve Name

#### 1.10.14.12 Field: Convection Coefficient 2 User Curve Name

If the Convection type was "UserCurve", then this field contains the name of a SurfaceConvectionAlgorithm:UserCurve input object describing the model equations to be used during the time intervals for the schedule.

In IDF usage:

```

9.8; ! Convection Coefficient 1
```

#### 1.10.15 SurfaceProperty:ConvectionCoefficients:MultipleSurface

The convection coefficients of each surface, both outside and inside, are automatically calculated during EnergyPlus execution. These calculations are "governed" by other objects such as the Inside Convection Algorithm (overall default) and the Zone Inside Convection Algorithm (Zone Default) and the Outside Convection Algorithm (overall default) and/or the Zone Outside Convection Algorithm (Zone Default). Usually, that will be enough flexibility for most users. However, if you need to match pre-existing convection coefficients (from another program) or are trying to match a test suite of results, you may wish to use the "override" convection coefficients in the following object. This object is similar to the preceding "ConvectionCoefficients" object but allows multiple surfaces to be assigned a type with one object entry.

Note that using these in conjunction, in particular, the "Simple" option on either the Outside Convection Algorithm or the Zone Outside Convection Algorithm field will result in a combined coefficient regardless of choice chosen here.

Note that surfaces with "SurfaceProperty:OtherSideCoefficients" cannot use this object with the "outside" coefficient – attempting to do so will ignore OSC surfaces during a multiple surface "apply"; SurfaceProperty:OtherSideCoefficients surfaces can apply an "inside" coefficient. And, surfaces with "Ground" exposure do not use the "outside" coefficient that might be supplied here. Note, too, that some lower boundaries are used regardless by certain surface types (i.e. Window) or certain algorithm types.

#### 1.10.15.1 Field: Surface Type

This field is the applicable surface name for the user supplied convection coefficient. The allowable surface types are:

- AllExteriorSurfaces (all surfaces that are “external environment” surfaces)
- AllExteriorWindows (all windows that are “external environment” surfaces)
- AllExteriorWalls
- AllExteriorRoofs
- AllExteriorFloors
- AllInteriorSurface (all surfaces that are “internal” surfaces)
- AllInteriorWindows
- AllInteriorCeilings
- AllInteriorFloors

#### 1.10.15.2 Fields (Convection Location, Type, Coefficient & Schedule Name)

For simplicity, the descriptions of these field occur together – however, the fields are used sequentially when put into the IDF file (reference the IDF examples following the descriptions).

#### 1.10.15.3 Field: Convection Coefficient 1 Location

#### 1.10.15.4 Field: Convection Coefficient 2 Location

This field contains the word “Outside” or “Inside” depending on which location is being described.

#### 1.10.15.5 Field: Convection Coefficient 1 Type

#### 1.10.15.6 Field: Convection Coefficient 2 Type

The entries can be of several types: Value (simple numeric value), Schedule (name of schedule with the values), the usual key choices for overall models for Outside or Inside (Simple, SimpleCombined, TARP, AdaptiveConvectionAlgorithm etc.), the key choices for individual convection equations used for customizing the adaptive algorithm, or a custom user defined correlation. The field should contain one of the keys listed in the table below along with face they can be applied. The definitions of the models and key choices are discussed under SurfaceConvectionAlgorithm:Inside , SurfaceConvectionAlgorithm:Outside, SurfaceConvectionAlgorithm:Inside:AdaptiveModelSelections, and SurfaceConvectionAlgorithm:Outside:AdaptiveModelSelections.

Key choice	Applies to Inside or Outside
Value	Both
Schedule	Both
Simple	Inside

#### 1.10.15.7 Field: Convection Coefficient 1

#### 1.10.15.8 Field: Convection Coefficient 2

If the Convection type was "Value", then this field is filled and contains the simple value to be used. Otherwise, this can be blank.

#### 1.10.15.9 Field: Convection Coefficient 1 Schedule Name

#### 1.10.15.10 Field: Convection Coefficient 2 Schedule Name

If the Convection type was "Schedule", then this field contains the name of a schedule describing the value to be used during the time intervals for the schedule.

#### 1.10.15.11 Field: Convection Coefficient 1 User Curve Name

#### 1.10.15.12 Field: Convection Coefficient 2 User Curve Name

If the Convection type was "UserCurve", then this field contains the name of a SurfaceConvectionAlgorithm:UserCurve input object describing the model equations to be used during the time intervals for the schedule.

In IDF usage:

```
SurfaceProperty:ConvectionCoefficients:MultipleSurface,
AllExteriorWindows, ! Surface Types
Outside, ! Convection Coefficient 1 Location
MoWitt; ! Convection Coefficient 1 Type
```

### 1.10.16 Convection Coefficient Application Hierarchy

Ultimate flexibility and possibly ultimate user confusion can result from the convection coefficient possibilities in EnergyPlus. The objects that control how convection models are assigned to individual surfaces are:

- SurfaceConvectionAlgorithm:Inside
- SurfaceConvectionAlgorithm:Outside
- Zone, Field: Zone Inside Convection Algorithm
- Zone, Field: Zone Outside Convection Algorithm
- SurfaceProperty:ConvectionCoefficients
- SurfaceProperty:ConvectionCoefficients:MultipleSurface

General to Specific, they are assigned in this order:

Table 9. Convection Coefficient Assignment Hierarchy

Objects/Description	Action
SurfaceConvectionAlgorithm:*	Assigns for all surfaces in the run.
Zone, Fields: Zone * Convection Algorithm	Trumps global assignment and assigns for all surfaces in Zone.
SurfaceProperty:....:MultipleSurfaces	Trumps above and assigns for specific types of surfaces.
Two Multiple Surface Assignments overlapping (such as AllExteriorSurfaces vs AllExteriorWalls)	Order in IDF is now important. Whichever is first gets the cookie and the second gets a warning.
Specific Surface Assignment	Trumps all Above.

There are additional objects that provide fine control over the models that get assigned.

- SurfaceConvectionAlgorithm:Inside:AdaptiveModelSelections
- SurfaceConvectionAlgorithm:Outside:AdaptiveModelSelections
- SurfaceConvectionAlgorithm:Inside:UserCurve
- SurfaceConvectionAlgorithm:Outside:UserCurve

### 1.10.17 Convection Coefficients Outputs

Outputs for the User Supplied Convection Coefficients appear as values in the Surface Output Variables *Surface Inside Face Convection Heat Transfer Coefficient* and *Surface Outside Face Convection Heat Transfer Coefficient*. What the program expects to use is shown in the Surface Details report (*Output:Surfaces:List, Details;*)

When EnergyPlus is set to Display Advanced Variables (*Output:Diagnostics, DisplayAdvancedVariables;*), then additional output variables are available that indicate the status of convection modeling by identifying which models are in effect at a given time. The adaptive convection algorithms may switch between models over time and the following output variables provide a way to monitor this behavior. These outputs are integer codes and the integer values are explained in tables.

#### 1.10.17.1 Surface Inside Face Convection Classification Index

This variable reports how the surface was classified as part of the adaptive convection algorithm for the inside face. The algorithm examines probable flow regimes, heat flow directions, orientations, HVAC equipment connections, and current operating status to assign each surface a category. The numbers in this report are integer codes that correspond to surface categories as described in the following table.

Cohc	Zone Airflow Regime	Type of surface	Heat Flow
1	A1 Radiant Heated Floor or Chilled Ceiling	Vertical Wall	Any
2	A1 Radiant Heated Floor or Chilled Ceiling	Horizontal	Stable
3	A1 Radiant Heated Floor or Chilled Ceiling	Horizontal	Unstable
4	A1 Radiant Heated Floor or Chilled Ceiling	Heated Floor	Unstable
5	A1 Radiant Heated Floor or Chilled Ceiling	Chilled Ceiling	Unstable
6	A1 Radiant Heated Floor or Chilled Ceiling	Tilted	Stable
7	A1 Radiant Heated Floor or Chilled Ceiling	Tilted	Unstable
8	A1 Radiant Heated Floor or Chilled Ceiling	Window	Any
9	A2 Radiant Wall Heat	Non-heated Vertical Wall	Any
10	A2 Radiant Wall Heat	Heated wall	Any
11	A2 Radiant Wall Heat	Horizontal	Stable
12	A2 Radiant Wall Heat	Horizontal	Unstable
13	A2 Radiant Wall Heat	Tilted	Stable
14	A2 Radiant Wall Heat	Tilted	Unstable

15	A2 Radiant Wall Heat	Windows	Any
16	A3 Simple Buoyancy	Vertical Walls	Any
17	A3 Simple Buoyancy	Horizontal	Stable
18	A3 Simple Buoyancy	Horizontal	Unstable
19	A3 Simple Buoyancy	Tilted	Stable
20	A3 Simple Buoyancy	Tilted	Unstable
21	A3 Simple Buoyancy	Windows	Any
22	B Convective Zone Heat	Vertical Walls	Any
23	B Convective Zone Heat	Vertical Walls near heater	Any
24	B Convective Zone Heat	Horizontal	Stable
25	B Convective Zone Heat	Horizontal	Unstable
26	B Convective Zone Heat	Tilted	Stable
27	B Convective Zone Heat	Tilted	Unstable
28	B Convective Zone Heat	Windows	Any
29	C Central Air Diffuser	Walls	Any
30	C Central Air Diffuser	Ceiling	Any
31	C Central Air Diffuser	Floor	Any
32	C Central Air Diffuser	Windows	Any
33	D Zone Fan Unit	Walls	Any
34	D Zone Fan Unit	Horizontal	Stable
35	D Zone Fan Unit	Horizontal	Unstable
36	D Zone Fan Unit	Tilted	Stable
37	D Zone Fan Unit	Tilted	Unstable
38	D Zone Fan Unit	Windows	Any
39	E Mixed Forced and Buoyancy	Walls	Assisting
40	E Mixed Forced and Buoyancy	Walls	Opposing
41	E Mixed Forced and Buoyancy	Floor	Stable
42	E Mixed Forced and Buoyancy	Floor	Unstable
43	E Mixed Forced and Buoyancy	Ceiling	Stable
44	E Mixed Forced and Buoyancy	Ceiling	Unstable
45	E Mixed Forced and Buoyancy	Windows	Any

### 1.10.17.2 Surface Inside Face Convection Model Equation Index

This variable reports the specific model equation used to calculate the inside face convection coefficient. This can vary when using the adaptive convection algorithm and so the result of that selection algorithm is reported here. The following table lists the models associated with specific interger codes reported here. The models correspond to key words used in input objects.

### 1.10.17.3 Surface Inside Face Convection Reference Air Index

The inside face convection heat transfer calculations can be based on different reference air temperatures. This reference air temperature can vary during the simulation when the adaptive algorithm selects models that use different references. The following table lists the meaning of the integer codes.

Report Code	Reference Air Temperature Method
1	Zone mean air temperature
2	Surface adjacent air temperature
3	Supply air temperature

### 1.10.17.4 Surface Outside Face Convection Classification Index

This variable reports how the surface was classified as part of the adaptive convection algorithm for the outside face. The algorithm examines the wind direction, heat flow directions and orientations to assign each surface a category. The numbers in this report are integer codes that correspond to surface categories as described in the following table.

Report Code	Surface Classification
101	Vertical Wall, Windward
102	Vertical Wall, Leeward
103	Roof, stable heat flow direction
104	Roof, unstable heat flow direction

### 1.10.17.5 Surface Outside Face Forced Convection Model Equation Index

### 1.10.17.6 Surface Outside Face Natural Convection Model Equation Index

These variables report the specific model equation used to calculate the outside face's convection coefficient. They can vary when using the adaptive convection algorithm and so the results of that selection algorithm are reported in these variables. The following table lists the models associated with specific integer codes that might be reported here. The models correspond to key words used in input objects.

### 1.10.18 SurfaceProperties:VaporCoefficients

Advanced/Research Usage: The internal and external vapor transfer coefficients that are used by the CombinedHeatAndMoistureFiniteElement model are automatically calculated during EnergyPlus execution using information on the convection coefficients. However it is sometimes useful to be able to “override” the calculation and set fixed values of vapor transfer coefficient for a single surface. These coefficients are only used by the CombinedHeatAndMoistureFiniteElement model and will be ignored by other solution algorithms.

#### 1.10.18.1 Field: Surface Name

This field is the applicable surface name for the user supplied vapor transfer coefficient.

#### 1.10.18.2 Field: Constant External Vapor Transfer Coefficient

Select ‘yes’ to use the value supplied as the external vapor transfer coefficient

#### 1.10.18.3 Field: External Vapor Coefficient Value

HAMT will use this value to calculate the vapour transfer into and out off the external surface of this surface. Units are kg/Pa.s.m2.

#### 1.10.18.4 Field: Constant Internal vapor Transfer Coefficient

Select ‘yes’ to use the value supplied as the internal vapor transfer coefficient

#### 1.10.18.5 Field: Internal Vapor Coefficient Value

The CombinedHeatAndMoistureFiniteElement algorithm will use this value to calculate the vapor transfer into and out of the internal surface of this surface. Units are kg/Pa.s.m2.

Below is an example input of vapor transfer coefficients for a surface.

```
SurfaceProperties:VaporCoefficients,
  South wall,      !- Surface Name
  Yes,            !- Constant External Vapor Transfer Coefficient
  0.0000000625,  !- External Vapor Coefficient Value
  Yes,           !- Constant Internal vapor Transfer Coefficient
  0.000000002;   !- Internal Vapor Coefficient Value
```

### 1.10.19 SurfaceProperty:ExteriorNaturalVentedCavity

This object is used to model a multi-skin exterior heat transfer surface. This is a special case where the outside face is a slightly detached layer forming a naturally ventilated cavity. The actual outer surface is referred to as the baffle. The modeling here assumes that the heat capacity in the outer baffle can be neglected since it is much lower than the underlying mass surface. This object is used with the BuildingSurface:Detailed object where the Heat Transfer surfaces are referred to as the underlying surfaces. The constructions and materials for the BuildingSurface:Detailed object should reflect the construction of just the underlying surface. The SurfaceProperty:ExteriorNaturalVentedCavity object is used to describe the decoupled layer, or baffle, and the characteristics of the cavity and openings for natural ventilation. This object is also used in conjunction with the OtherSideConditionsModel.

The area and orientation are obtained from **BuildingSurface:Detailed** objects, which are referenced by name. This object can be used to model certain types of photovoltaic mounting configurations such as interlocking roof pavers. If the baffle covers only part of a surface, then that surface should be split into separate **BuildingSurface:Detailed** objects where one matches the size of the baffle. A single baffle can be associated with as many **BuildingSurface:Detailed** objects

as desired (although if you need to use more than 10 surfaces, then the IDD will need to be extended). The base heat transfer surfaces need not be contiguous nor have the same orientation, but the program will issue warnings if surfaces have widely ranging tilts and azimuths.

Note that the model involves predicting the rates that ambient air moves in and out of the cavity. Accurate modeling of these air flows would be extremely challenging and so the models provided through this object are simplistic engineering models based on discharge coefficients that are sensitive to wind and buoyancy effects. The accuracy depends on the values for, and applicability of, the discharge coefficients and unfortunately little research is available to help characterize these. The models should be considered rudimentary and the user is encouraged to explore different values for the coefficients in attempts to bound the importance of natural ventilation for the cavities. See the Engineering Reference for more details.

#### **1.10.19.1 Field: Name**

This field contains a unique name for the ventilated cavity.

#### **1.10.19.2 Field: Boundary Conditions Model Name**

This field contains the name of an `SurfaceProperty:OtherSideConditionsModel` object declared elsewhere in the input file. This will connect the baffle and ventilated cavity to the exterior boundary conditions for the underlying heat transfer surface.

#### **1.10.19.3 Field: Area Fraction of Openings**

This field is used to enter an area fraction for what part of the baffle consists of openings. The area of the openings will set to the product of this field and the sum of the area of the underlying surfaces.

#### **1.10.19.4 Field: Thermal Emissivity of Exterior Baffle Material**

This field is used to enter the thermal emissivity of the baffle. This surface property is for longwave infrared radiation. The property is used for both sides of collector. Most painted materials have an emissivity of 0.9.

#### **1.10.19.5 Field: Solar Absorptivity of Exterior Baffle**

This field is used to enter the solar absorptivity of the baffle. This surface property is for shortwave, solar radiation. The property is used for the front side of the baffle that faces the environment. Darker colors have a higher absorptivity. While black is the highest performance, other colors might be used to match the color scheme of the rest of the façade.

#### **1.10.19.6 Field: Height Scale for Buoyancy-Driven Ventilation**

This field is used to enter a nominal height scale (m) for prediction of ventilation induced by buoyancy. This value ( $\Delta H_{NPL}$ ) is defined as the height from the midpoint of the lower opening to the neutral pressure level. Increasing the value will increase the ventilation rate due to buoyancy.

#### **1.10.19.7 Field: Effective Thickness of Cavity Behind Exterior Baffle**

This field is used to enter a nominal gap thickness (m) for the collector. If the baffle is corrugated, use the average depth. This distance value is only used when the collector is near horizontal to determine a length scale in the vertical direction for buoyancy calculations. For example, if the collector is mounted on a flat roof, its tilt-adjusted height is zero and the program will use this gap thickness as a length scale rather than the height from the previous field.

#### **1.10.19.8 Field: Ratio of Actual Surface Area to Projected Surface Area**

This field is used to enter a factor that accounts for the extra surface area resulting from an uneven baffle surface. Corrugations may be present to help stiffen the baffle or ventilated roofing tiles may have more surface area for convection heat transfer than the underlying surface. The projected surface area is obtained by the program from the (flat) underlying surfaces. If the baffle is flat then this ratio is 1.0. If the baffle is corrugated, then this ratio will be greater than one with a typical value might be 1.165.

#### **1.10.19.9 Field: Roughness of Exterior Surface**

This field is used to describe the relative roughness of the baffle material. This field is similar to one in the `Material` object. This parameter only influences the convection coefficients, more specifically the exterior convection coefficient. A special keyword is expected in this field with the options being "VeryRough", "Rough", "MediumRough", "MediumSmooth", "Smooth", and "VerySmooth" in order of roughest to smoothest options.

#### **1.10.19.10 Field: Effectiveness for Perforations with Respect to Wind**

This field is used to enter a value for the coefficient used to determine natural air exchanges from wind. Wind will cause exterior air to move in and out of the cavity.  $C_v$  is an arbitrary coefficient used to model the effectiveness of openings and depends on opening geometry and the orientation with respect to the wind.  $C_v$  should probably be in the range 0.05 to 0.65. Increasing  $C_v$  will increase the amount of natural ventilation. The following equation shows how  $C_v$  is used in the program to predict the volumetric flow rate due to wind:

Missing argument for \rlap

### 1.10.19.11 Field: Discharge Coefficient for Openings with Respect to Buoyancy Driven Flow

This field is used to enter a value for the coefficient used to determine natural air exchanges from buoyancy. Stack or buoyancy effects will cause exterior air to move in and out of the cavity. Cd is an arbitrary discharge coefficient that depends on the geometry of the opening. Cd should probably be in the range 0.1 to 1.0. Increasing Cd will increase the amount of natural ventilation. The following equations show how Cd is used in the program to predict the volume flow rate due to buoyancy:

Missing argument for \rlap (if  $T_{a,cav} > T_{amb}$ )

Missing argument for \rlap (if  $T_{amb} > T_{a,cav}$  and baffle is vertical)

where  $\Delta H_{NPL}$  is the value input into the field above for the height scale for buoyancy-driven ventilation.

### 1.10.19.12 Field(s): Surface <1 thru x> Name

The remaining fields are used to name the **BuildingSurface:Detailed** objects that are associated with the exterior naturally vented cavity. These are the underlying heat transfer surfaces and are defined elsewhere in the input file. These surfaces should all specify **OtherSideConditionsModel** as their exterior environment. The input object can currently accommodate up to ten surfaces, but it is extensible by modifying the Energy+.idd entry.

An example IDF entry is

```
SurfaceProperty:ExteriorNaturalVentedCavity,
PVRoofPaverExtVentCav1 , ! Name
PVRoofPaverSystem1, ! OtherSideConditionsModel Object Name
0.02, ! Area Fraction of Openings
0.9, ! Thermal Emissivity of Exterior Baffle Material
0.92, ! Solar Absorbtivity of Exterior Baffle
0.05, ! Height scale for buoyancy-driven ventilation
0.05, ! Effective Thickness of Cavity Behind Exterior Baffle
0.97, ! Ratio of Actual surface area to projected surface area
Smooth, ! Roughness of collector
0.1, ! Cv, Effectiveness for perforations with respect to Wind
0.5, ! Cd, Discharge Coefficient for Openings with respect to buoyancy-driven flow
Zn001:Roof001 ; ! Surface Name
```

### 1.10.20 SurfaceProperty:ExteriorNaturalVentedCavity Outputs

In addition to related output that can be obtained for all surfaces, these outputs are available for exterior naturally vented cavity configurations:

- HVAC,Average, Surface Exterior Cavity Air Drybulb Temperature [C]
- HVAC,Average, Surface Exterior Cavity Baffle Surface Temperature [C]
- HVAC,Average, Surface Exterior Cavity Total Natural Ventilation Air Change Rate [ACH]
- HVAC,Average, Surface Exterior Cavity Total Natural Ventilation Mass Flow Rate [kg/s]
- HVAC,Average, Surface Exterior Cavity Natural Ventilation from Wind Mass Flow Rate [kg/s]
- HVAC,Average, Surface Exterior Cavity Natural Ventilation from Buoyancy Mass Flow Rate [kg/s]

#### 1.10.20.1 Surface Exterior Cavity Air Drybulb Temperature [C]

The temperature of air inside the cavity behind the baffle.

#### 1.10.20.2 Surface Exterior Cavity Baffle Surface Temperature [C]

The surface temperature of the exterior baffle material itself.

#### 1.10.20.3 Surface Exterior Cavity Total Natural Ventilation Air Change Rate [ACH]

The rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive in Air Changes per Hour.

#### 1.10.20.4 Surface Exterior Cavity Total Natural Ventilation Mass Flow Rate [kg/s]

The mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive.

#### 1.10.20.5 Surface Exterior Cavity Natural Ventilation from Wind Mass Flow Rate [kg/s]

The part of mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive due to wind-driven forces.

#### 1.10.20.6 Surface Exterior Cavity Natural Ventilation from Buoyancy Mass Flow Rate [kg/s]

The part of mass flow rate of natural ventilation air exchange between the plenum and ambient when the collector is inactive due to buoyancy-driven forces.

### 1.10.21 SurfaceProperty:SolarIncidentInside

This object can be used as an alternative to the standard (automatic) EnergyPlus calculation of the solar radiation incident on interior surfaces of the building. Using this method, the normal EnergyPlus calculation is replaced with a schedule of solar incidence values that are calculated outside the program.

#### 1.10.21.1 Field: Name

The name of the SurfaceProperty:SolarIncidentInside object Must be unique between all SurfaceProperty:SolarIncidentInside objects.

#### 1.10.21.2 Field: Surface Name

The building surface associated with this object (ref BuildingSurface:Detailed). Solar absorptance values in the schedule file will be applied to the inside of this surface.

#### 1.10.21.3 Field: Construction Name

The building construction associated with this object (ref Construction). It is possible that the Energy Management System will change the construction associated with the surface; if the construction is changed, a new set of data may need to be applied to the current surface.

#### 1.10.21.4 Field: Inside Surface Incident Sun Solar Radiation Schedule Name

This field specifies the name of a schedule that contains the values for incident solar radiation. Values from the schedule data will be used to replace the absorbed solar radiation that would normally be calculated by EnergyPlus. Units in the external schedule file must be  $W/m^2$ .

Example for SurfaceProperty:SolarIncidentInside using a compact schedule:

```
Schedule:Compact,  
North Wall SSG,           !- Name  
Positive Number,         !- Schedule Type Limits Name  
Through: 12/31,          !- Field 1  
For: AllDays,            !- Field 2  
Until: 07:00,10,         !- Field 3  
Until: 17:00,20,         !- Field 5  
Until: 24:00,15;         !- Field 7
```

```
SurfaceProperty:SolarIncidentInside,  
North Wall Solar Incident, !- Name  
Room102 North Wall,       !- Surface Name  
Room Wall - North,        !- Construction Name  
North Wall SSG;           !- Schedule Name
```

### 1.10.22 ComplexFenestrationProperty:SolarAbsorbedLayers

This object can be used as an alternative to the standard (automatic) EnergyPlus calculation of the solar radiation absorbed by fenestration systems in the building. Using this method, the normal EnergyPlus calculation is replaced with a schedule of solar absorptance values that are calculated outside the program.

#### 1.10.22.1 Field: Name

The name of the ComplexFenestrationProperty:SolarAbsorbedLayers object Must be unique between all ComplexFenestrationProperty:SolarAbsorbedLayers objects.

#### 1.10.22.2 Field: Fenestration Surface

The fenestration surface associated with this object (ref FenestrationSurface:Detailed). Values from the schedule data will be used to replace the absorbed solar radiation in the fenestration layers that would normally be calculated by EnergyPlus. Value units in the schedule must be  $W/m^2$ .

#### 1.10.22.3 Field: Construction Name

The building construction associated with this object (ref Construction). It is possible that the Energy Management System will change the construction associated with the surface; if the construction is changed, a new set of data may need to be applied to the current surface.

#### 1.10.22.4 Field: Layer 1 Solar Radiation Absorbed Schedule Name

Specifies the name of a schedule that contains the absorbed solar radiation values in units of  $W/m^2$ . Values from the schedule are used for the absorbed solar radiation of the first (outside) layer .

#### 1.10.22.5 Field: Layer 2 Solar Radiation Absorbed Schedule Name

Specifies the name of a schedule that contains absorbed solar radiation values in units of  $W/m^2$ . Values from the schedule are used for the absorbed solar radiation of the second layer .

#### 1.10.22.6 Field: Layer 3 Solar Radiation Absorbed Schedule Name

Specifies the name of a schedule that contains absorbed solar radiation values in units of  $W/m^2$ . Values from the schedule are used for the absorbed solar radiation for the third layer .

#### 1.10.22.7 Field: Layer 4 Solar Radiation Absorbed Schedule Name

Specifies the name of a schedule that contains absorbed solar radiation values in units of  $W/m^2$ . Values from the schedule are used for the absorbed solar radiation of the fourth layer.

#### 1.10.22.8 Field: Layer 5 Solar Radiation Absorbed Schedule Name

Specifies the name of a schedule that contains absorbed solar radiation values in units of  $W/m^2$ . Values from the schedule are used for the absorbed solar radiation of the fifth layer .

Example for ComplexFenestrationProperty:SolarAbsorbedLayers with compact schedules:

```
Schedule:Compact,
  Layer 1,           !- Name
  Positive Number,  !- Schedule Type Limits Name
  Through: 12/31,   !- Field 1
  For: AllDays,     !- Field 2
  Until: 07:00,1,   !- Field 3
  Until: 17:00,2,   !- Field 5
  Until: 24:00,1.5; !- Field 7
```

```
Schedule:Compact,
  Layer 2,           !- Name
  Positive Number,  !- Schedule Type Limits Name
  Through: 12/31,   !- Field 1
  For: AllDays,     !- Field 2
  Until: 07:00,0.8, !- Field 3
  Until: 17:00,1.2, !- Field 5
  Until: 24:00,1.0; !- Field 7
```

```
Schedule:Compact,
  Layer 3,           !- Name
  Positive Number,  !- Schedule Type Limits Name
  Through: 12/31,   !- Field 1
  For: AllDays,     !- Field 2
  Until: 07:00,1,   !- Field 3
  Until: 17:00,2.1, !- Field 5
  Until: 24:00,1.7; !- Field 7
```

```
ComplexFenestrationProperty:SolarAbsorbedLayers,
  South Window Solar Absorbed Layers, !- Name
  Room 102 South Window,             !- Fenestration surface name
  CFS_Glz_2,                          !- Construction Surface name
  Layer 1,                             !- Absorbed solar energy in layer 1
  Layer 2,                             !- Absorbed solar energy in layer 2
  Layer 3;                             !- Absorbed solar energy in layer 3
```

### 1.10.23 GeometryTransform

This object provides a simple method of altering the footprint geometry of a model. The intent is to provide a single parameter that can be used to reshape the building description contained in the rest of the input file. This object was implemented for use in parametric massing studies and with the optimization program GenOpt. Although building footprint is often constrained in practice, analysts may find this object useful for investigating how building form impacts daylighting and solar gains on the east and west facades with out having to change all of the surface geometry input.

Aspect Ratio is defined as the overall length in the East-West direction divided by the overall length in the North-South direction.

This object should be used with considerable care since it will completely alter the geometry modeled by EnergyPlus and may have unintended side effects. The surface areas of all horizontal surfaces may change radically with corresponding changes in Zone floor areas. The total floor area will not change but individual horizontal surfaces will gain and loose area. Vertical surfaces will have the same height but will gain and lose length. Lighting and electrical equipment design levels for individual zones will likely have a different energy per unit area in the transformed geometry.

The surface geometry must be set to **Relative**, see **GlobalGeometryRules**. Of course, the coordinates must be entered in relative coordinates as well.

Since windows in EnergyPlus need to be rectangular, it is possible to define a horizontal window (skylight) that once transformed is no longer rectangular and will cause EnergyPlus to halt. To avoid this problem, horizontal windows should be defined orthogonal to the Cardinal directions and building rotation (see **Building**) used to orient the final form with respect to North.

The object doesn't create any specific output, but the results of using it can be understood by viewing DXF output files. Figure 43 shows an example of a building that has been morphed using the Aspect Ratio Transform object. Using this object allowed the same geometry input to generate both of the models represented in by their DXF output files.

Figure 43. Example of Geometry Transform -- Aspect Ratio

#### 1.10.23.1 Field: Plane of Transform

This field specifies the plane that the geometry transform should act on. It is currently restricted to altering the horizontal footprint of a building and must be set to "XY."

#### 1.10.23.2 Field: Current Aspect Ratio

This field specifies the aspect ratio of the building geometry described in the rest of the input file. It is used to scale the new aspect ratio. If this field is set to 1.0, then the altered building will not necessarily have the new aspect ratio defined in the next field.

#### 1.10.23.3 Field: New Aspect Ratio

This field specifies the aspect ratio that the building described in the rest of the input file will be changed to.

### 1.10.24 Zone Property View Factors

EnergyPlus has two options for specifying the thermal radiation exchange view factors between surfaces in a zone: the approximate option and the user input option. Because the actual geometric arrangement within a zone is very complex, the approximate method of including thermal mass and other forced exchanges is more realistic than trying to come up with "exact" view factors. However, in some research situations it might be desirable to have control of the view factors used. For this reason, a user input mode has been included in EnergyPlus. The two modes are described in the next sections.

#### 1.10.24.1 Approximate Option

The first option produces approximate results and uses an area weighted scheme to calculate "view factors" between surfaces within a thermal zone. Each surface uses the total area that it can "see" among the other surfaces. The approximate view factor from this surface to each other surface is then the area of the receiving surface over the sum of areas that are visible to the sending surface.

In order to account in some limited way for the fact that certain surfaces will not see each other, several assumptions have been built into this view factor approximation. First, a surface cannot see itself. Second, surfaces with approximately the same azimuth (facing direction) and tilt ("same" being within a built in limit) will not see each other. This means that a window will not see the wall that it is placed on, for example. Third, floors cannot see each other. Fourth, if the surface is a floor, ceiling, roof, or internal mass, the rule for the same azimuth and tilt eliminating radiant exchange between surfaces is waived when the receiving surface is floor, roof, ceiling, or internal mass as long as both surfaces are not floors.

Note that this does not take into account that surfaces may be "around the corner" from each other and in reality not see each other at all. Rooms are assumed

to be convex rather than concave in this method.

To summarize, using the Surface “Class”, the approximate view factors have:

1. No surface sees itself.
2. No Floor sees another floor.
3. All other surface types see Internal Mass.
4. All other surface types see floors.
5. Floors always see ceilings.
6. Floors always see roofs.
7. All other surfaces whose tilt or facing angle differences are greater than 10 degrees see each other.

If geometry is correct, conditions 1,3, and 7 should take care of all surfaces, but the other conditions supply common sense when the geometry is incorrect. More information about the EnergyPlus view factor calculation is contained in the Engineering Reference document.

#### 1.10.24.2 User Input View Factors

The second option for specifying view factors requires user input values. These should be used with care in research or special situations. The object available for this is `ZoneProperty:UserViewFactors:bySurfaceName`.

#### 1.10.25 ZoneProperty:UserViewFactors:bySurfaceName

The method of entering user view factors is to enter each surface name and its view factor value to other surfaces in the zone

##### 1.10.25.1 Field: Zone Name

This field is the zone name for the view factors.

##### 1.10.25.2 Field: From Surface 1

This field specifies the name of the “from surface”.

##### 1.10.25.3 Field: To Surface 1

This field specifies the name of the “to surface”.

##### 1.10.25.4 Field: Factor 1

This value is the view factor for “from Surface” to “to Surface”.

An IDF Example:

```
ZoneProperty:UserViewFactors:bySurfaceName,Lshaped Zone,  
  Lshaped Zone:South Wall,Lshaped Zone:South Wall,0.000000,  
  Lshaped Zone:South Wall,Lshaped Zone:East Wall,0.101310,  
<snip>
```

## 1.11 Group – Detailed Ground Heat Transfer

### 1.11.1 Detailed Ground Heat Transfer

The following objects may be included in an EnergyPlus input IDF file but are handled by the Slab preprocessor:

- `GroundHeatTransfer:Slab:Materials`
- `GroundHeatTransfer:Slab:MatlProps`
- `GroundHeatTransfer:Slab:BoundConds`
- `GroundHeatTransfer:Slab:BldgProps`
- `GroundHeatTransfer:Slab:Insulation`
- `GroundHeatTransfer:Slab:EquivalentSlab`
- `GroundHeatTransfer:Slab:AutoGrid`

- GroundHeatTransfer:Slab:ManualGrid
- GroundHeatTransfer:Slab:XFACE
- GroundHeatTransfer:Slab:YFACE
- GroundHeatTransfer:Slab:ZFACE

The following objects may be included in an EnergyPlus input IDF file but are handled by the Basement preprocessor:

- GroundHeatTransfer:Basement:SimParameters
- GroundHeatTransfer:Basement:MatlProps
- GroundHeatTransfer:Basement:Insulation
- GroundHeatTransfer:Basement:SurfaceProps
- GroundHeatTransfer:Basement:BldgData
- GroundHeatTransfer:Basement:Interior
- GroundHeatTransfer:Basement:ComBldg
- GroundHeatTransfer:Basement:EquivSlab
- GroundHeatTransfer:Basement:EquivAutoGrid
- GroundHeatTransfer:Basement:AutoGrid
- GroundHeatTransfer:Basement:ManualGrid
- GroundHeatTransfer:Basement:XFACE
- GroundHeatTransfer:Basement:YFACE
- GroundHeatTransfer:Basement:ZFACE

The documentation both the Slab and Basement objects appear in the AuxiliaryPrograms document under the “Ground Heat Transfer in EnergyPlus” heading.

The only object described in this section is the control object which activates the use of the preprocessor.

### 1.11.2 GroundHeatTransfer:Control

The GroundHeatTransfer:Control object determines if the Slab and Basement preprocessors are going to be executed. When a Slab or Basement run is performed the results are saved in files with extensions .SLAB or .BSMT so that they do not need to be rerun if no input changes are made to the GroundHeatTransfer:Slab or GroundHeatTransfer:Basement objects.

#### 1.11.2.1 Field: Name

This alpha field is the name of the GroundHeatTransfer:Control object. It is used as an identifier.

#### 1.11.2.2 Field: Run Basement Preprocessor

The field can either be Yes or No and defaults to No. It is used to control whether the Basement preprocessor program is executed. If it has been previously executed the results are stored in the .BSMT file and do not necessary need to be run again unless the GroundHeatTransfer:Basement objects have changed.

#### 1.11.2.3 Field: Run Slab Preprocessor

The field can either be Yes or No and defaults to No. It is used to control whether the Slab preprocessor program is executed. If it has been previously executed the results are stored in the .SLAB file and do not necessary need to be run again unless the GroundHeatTransfer:Slab objects have changed.

## 1.12 Group – Room Air Models

### 1.12.1 Room Air Models

The group of input objects described in this section is used to account for non-uniform room air temperatures that may occur within the interior air volume of a zone. Room air modeling was added to EnergyPlus starting with Version 1.2. Although there are many types of analyses (comfort, indoor air quality, etc) that might benefit from localized modeling of how room air varies across space, only the *temperature* distribution of room air within the zone is currently addressed in EnergyPlus. This allows surface heat transfer and air system heat balance calculations to be made taking into account natural thermal stratification of air and different types of intentional air distribution designs such as under-floor and side-wall displacement ventilation that purport to extract room air at higher-than-

mean temperatures. Note that EnergyPlus does **not** have completely general methods of modeling room air that are applicable to every conceivable type of airflow that might occur in a zone. Such models (e.g. RANS-CFD) are too computationally expensive to use with EnergyPlus for the foreseeable future. The models that are available in EnergyPlus offer only limited modeling capabilities for select room airflow configurations. Also note that because the complete mixing model for room air has long been the standard in building energy simulation, there is not currently a consensus on how to best model non-uniform air temperatures in buildings. Therefore, it is up to the user to have a good understanding of when, where, and how to apply the room air models available in EnergyPlus. The rest of this section provides some guidance in the way of examples and further discussion of the models available in EnergyPlus.

EnergyPlus offers the different types of air models listed in the table below along with the input objects associated with the use of that model.

Table 10. Summary of Room Air Models

Air Model Key	Air model Algorithm	Applicability	Input Objects Required
Mixing	Well-Mixed	All zones	None, default
UserDefined	User Defined	All zones	'RoomAirModelType', 'RoomAir:TemperaturePattern:UserDefined', RoomAir:TemperaturePattern:****
OneNodeDisplacementVentilation	Mundt	displacement ventilation	'RoomAirModelType', 'RoomAirSettings:OneNodeDisplacementVentilation', 'RoomAir:Node'
ThreeNodeDisplacementVentilation	UCSD Displacement Ventilation	displacement ventilation	'RoomAirModelType', 'RoomAirSettings:ThreeNodeDisplacementVentilation'
UnderFloorAirDistributionInterior	UCSD UFAD Interior Model	Interior zones served by a UFAD system	'RoomAirModelType', 'RoomAirSettings:UnderFloorAirDistributionInterior'
UnderFloorAirDistributionExterior	UCSD UFAD Exterior Model	Exterior zones served by a UFAD system	'RoomAirModelType', 'RoomAirSettings:UnderFloorAirDistributionExterior'
CrossVentilation	UCSD Cross Ventilation	cross ventilation	'RoomAirModelType', 'RoomAirSettings:CrossVentilation'

### 1.12.2 RoomAirModelType

EnergyPlus uses the RoomAirModelType object to determine which air model is available for use in a given zone during the simulation. If no RoomAirModelType object is specified (for each zone or the whole building), then EnergyPlus will run with the conventional, completely mixing air model (for each zone or the whole building). Include a RoomAirModelType for each zone that the user wants modeled using a more detailed method. Currently only a single RoomAirModelType object can be specified for each zone; you cannot switch between models during a simulation. However, the UCSD Displacement, Cross Ventilation and UFAD models switch from displacement to mixing ventilation when the operating conditions do not give rise to unmixed flow. The following parameters are fields required by the RoomAirModelType object.

#### 1.12.2.1 Field: Name

This alpha field is the air model name selected by user. It is used as an identifier

#### 1.12.2.2 Field: Zone Name

This alpha field indicates the unique name of a Zone object defined elsewhere in the input file. The type of room air model selected will be applied to this zone.

#### 1.12.2.3 Field: Room-Air Modeling Type

This alpha field indicates the room-air model used for the specified zone. Currently, there are three options for different air models. Entering the keyword 'Mixing' specifies the conventional complete-mixing air model. Note that Mixing is the default and no RoomAirModelType object would be needed to use the complete-mixing model. Entering the keyword 'UserDefined' specifies the User Defined Room Air Temperature Patterns. Entering the keyword 'OneNodeDisplacementVentilation' specifies the Mundt one node displacement ventilation air model for displacement ventilation. Entering the keyword 'ThreeNodeDisplacementVentilation' specifies the three-node displacement ventilation model developed by the University of California, San Diego (UCSD DV). Entering the keyword 'CrossVentilation' specifies the two-zone cross ventilation model developed by the University of California, San Diego (UCSD CV). Entering the keyword 'UnderFloorAirDistributionInterior' specifies the two-node interior zone under floor air distribution model developed by the University of California, San Diego (UCSD UFI). Entering the keyword 'UnderFloorAirDistributionExterior' specifies the two-node exterior zone under floor air distribution model developed by the University of California, San Diego (UCSD UFE).

#### 1.12.2.4 Field: Air Temperature Coupling Strategy

This alpha field indicates how air temperatures predicted by the air models are used by the surface heat balance calculation. Two different coupling schemes are available: Direct (also known as *T-couple*) or Indirect (*DT-couple*). In general, indirect coupling is more suited to situations where room air is well controlled and/or the room air model is less robust. Direct coupling is more suited for floating zone air temperatures and/or accurate room air models.

The Mundt model can use either coupling scheme; the UCSD DV, UCSD CV, UCSD UFI, and UCSD UFE models ignore this field and use direct coupling.

Input either *Direct* or *Indirect*

An example idf entry follows

```
RoomAirModelType,  
  MOD1,      !- Room-Air Model Name  
  ZONE ONE,  !- Zone Name  
  ThreeNodeDisplacementVentilation, !- Room-Air Modeling Type  
  Direct;    !- Air Temperature Coupling Strategy
```

### 1.12.3 RoomAir:TemperaturePattern:UserDefined

This object is used to explicitly define temperature patterns that are to be applied to the mean air temperature within a thermal zone. This Room Air modeling option is made available for a number of reasons. It allows modeling the consequences of air temperature variations during the design phase when little information is available about the specifics of the air distribution system or positioning of various loads. This option can be used to evaluate the energy implications of different design targets for the temperature patterns. It also provides a method of modeling the annual energy use implications for air temperature distributions determined using separate analyses or measurements. For example, this option could be used to understand the annual energy implications of an air distribution system that has been previously analyzed using Computational Fluid Dynamics.

This approach differs from the other Room Air modeling in that the static temperature pattern is not *really modeled* so that it will respond to conditions that develop during the simulation. More sophisticated dynamic Room Air models will adjust the temperature pattern based on various factors, such as air system flow rate, floor temperature, or rates of internal heat gains. The user-defined temperature distribution patterns are fixed at the beginning and EnergyPlus simply provides results that include the implications of those patterns. This user-defined distribution option may also be useful for checking dynamic Room Air models by using “bounding” analysis.

Note that using this object carries a certain degree of responsibility. It would be very easy to define a pattern that is non-physical and will lead to erroneous results. The user-defined temperature distributions should (probably) be balanced about the mean so that basic conservation of energy laws are not violated.

#### 1.12.3.1 Field: Name

This field provides a unique name for this object.

#### 1.12.3.2 Field: Zone Name

This field provides the unique name of a zone described elsewhere in the file.

#### 1.12.3.3 Field: Availability Schedule Name

This field provides the name of a schedule that will determine if this model is available. When not available the room air is modeled as completely mixed. When it is available, then a user-defined temperature distribution will be applied. This schedule should be set to “1.0” when model is available and “0.0” when the model is not to be used. If this field is blank, the schedule has values of 1 for all time periods.

#### 1.12.3.4 Field: Pattern Control Schedule Name

This field provides the name of schedule that will be used to control which user-defined RoomAir temperature pattern will be applied at any given time. This schedule needs to have integer values that are closely coordinated with those defined as the second field in one of the RoomAir:TemperaturePattern:\* objects described below. These schedule values provide the link to the actual patterns to be used throughout the day. This allows controlling which user-defined pattern is used at different times during the simulation. For example, one could use one pattern when the air system is scheduled to be on, and a different pattern when the air system is schedule to be off. Or if the user has knowledge of how the air temperature pattern changes over the course of day in response to changing thermal loads, then this schedule can be used to control when individual patterns are used. For example, a control schedule could use a pattern designated as number 100 from 18:00 to 6:00, pattern number 200 from 6:00 to 12:00, and pattern number 300 from 12:00 to 18:00.

An example of this object is

```
RoomAir:TemperaturePattern:UserDefined,  
  Ground Floor South Air Temp Contrls , ! Name  
  ZN2_S_1 ,          ! Zone Name  
  Always_on ,       ! Availability Schedule Name  
  Roomair Pattern 1; ! Pattern Control Schedule Name
```

### 1.12.4 RoomAir:TemperaturePattern:ConstantGradient

This object is used to model room air with a fixed temperature gradient in the vertical direction. This fixed-slope method is about the simplest distribution pattern.

In addition to the vertical temperature gradient, there are three other parameters included in the pattern that are important. The first two might affect how the air system conditioning the room is operated. The first describes the temperature difference between the mean air temperature and the point where the sensor of a drybulb thermostat is situated. The second describes the temperature difference between the mean and the point where system air is being extracted from the zone. This is considered important because the changes in temperature difference between supply and return can affect how an air system is controlled to meet the loads. The third parameter can affect the zone air heat balance by altering the temperature of the air leaving the zone through exhaust fans.

One example of a source of input data for the vertical temperature gradient is ANSI/ASHRAE Standard 55-2004 Thermal Environmental Conditions for Human Occupancy. Table 5.2.4.3 in this Standard specifies an allowable vertical temperature difference between head level and ankle level of 3°C (5°F). If we assume a

head to ankle length scale of 1.5 m (5 ft), this leads to a temperature gradient of 3°C/1.5m, or 2.0 °C/m.

#### 1.12.4.1 Field: Name

This field provides a unique name for this object.

#### 1.12.4.2 Field: Control Integer for Pattern Control Schedule Name

This field should contain an integer value that is unique among all other RoomAir:TemperaturePattern:\* objects. The value used here needs to be in the Pattern Control Schedule for those times when this pattern is to be used for the Room Air Temperature Distribution.

#### 1.12.4.3 Field: Thermostat Offset

This field specifies the temperature difference between where the thermostat is situated and the mean air temperature.

#### 1.12.4.4 Field: Return Air Offset

This field specifies the temperature difference between the air leaving the zone and returning to the air system and the mean air temperature.

#### 1.12.4.5 Field: Exhaust Air Offset

This field specifies the temperature difference between the air leaving the zone and being exhausted out of the building and the mean air temperature.

#### 1.12.4.6 Field: Temperature Gradient

This field specifies the gradient, or slope, of temperature changes in the vertical direction in °K/m.

An example of this object is:

```
RoomAir:TemperaturePattern:ConstantGradient,  
  half C per Meter,           ! Name  
  10005,      ! Control Integer for Pattern Control Schedule Name  
  0.0,        ! Thermostat Offset (Temp at thermostat- Mean Air Temp) [C]  
  1.0,        ! Return Air Offset (Tleaving - Mean Air Temp ) [C]  
  1.0,        ! Exhaust Air Offset (Texhaust - Mean Air Temp) [C]  
  0.5;        ! Temperature Gradient [K/m]
```

### 1.12.5 RoomAir:TemperaturePattern:TwoGradient

This object provides various controls over the value of the gradient used for determining the pattern of room air temperatures. It is similar to previous object RoomAir:TemperaturePattern:ConstantGradient object but simplifies the potentially arduous task of preparing and scheduling a large number of those objects. With this object, two different gradients are entered and user is given several options for controlling how the program will interpolate between the two bounds. The user inputs the height of the location of thermostat, return air, and exhaust air in meters rather than the temperature offset.

#### 1.12.5.1 Field: Name

This field provides a unique name for this object.

#### 1.12.5.2 Field: Control Integer for Pattern Control Schedule Name

This field should contain an integer value that is unique among all other RoomAir:TemperaturePattern:\* objects. The value used here needs to be in the Pattern Control Schedule for those times when this pattern is to be used for the Room Air Temperature Distribution.

#### 1.12.5.3 Field: Thermostat Height

This field specifies the distance above the floor where the thermostat is situated. This height is used by the model to determine the thermostat temperature relative to the mean air temperature by applying the gradient.

#### 1.12.5.4 Field: Return Air Height

This field specifies the distance above the floor where the air leaves the zone and returns to the air system. and the mean air temperature. This height is used by the model to determine the return air temperature relative to the mean air temperature by applying the gradient.

#### 1.12.5.5 Field: Exhaust Air Height

This field specifies the distance above the floor where the air leaves the zone and enters and exhaust device such as an exhaust fan. This height is used by the model to determine the exhaust air temperature relative to the mean air temperature by applying the gradient.

#### 1.12.5.6 Field: Temperature Gradient Lower Bound

This field specifies the gradient, or slope, of temperature changes in the vertical direction in °C/m.

#### 1.12.5.7 Field: Temperature Gradient Upper Bound

This field specifies the gradient, or slope, of temperature changes in the vertical direction in °C/m.

#### 1.12.5.8 Field: Gradient Interpolation Mode

This field specifies how the program will vary between the two gradients. Select one of the following keywords to choose the simulation data used to scale: 'Outdoor Environment Drybulb Temperature', 'Zone Drybulb Temperature', 'Delta Outdoor and Zone Temperature', 'Sensible Cooling Load', and 'Sensible Heating Load'. These are explained in detail below. All of these options have several things in common. They are essentially hard-coded. There is no support for a general method. The interpolation scheme is based on some variable that might reasonably be expected to correlate with gradient changes. This variable's current value is used to continually adjust the value of the vertical gradient for room air temperature.

**OutdoorDryBulbTemperature:** This key directs the program to interpolate between upper and lower values of the vertical gradient based on the outdoor air temperature. If the outdoor temperature exceeds the upper limit set in the next field, then the gradient entered in the 'Temperature Gradient Upper Bound' field is used. Similarly if the outdoor air temperature is below the value set in the 'Lower Temperature' field, then the gradient entered in the 'Temperature Gradient Lower Bound' is used. For outdoor temperatures that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.

**ZoneDryBulbTemperature:** This key directs the program to interpolate between upper and lower values of the vertical gradient based on the mean zone air temperature. If the mean zone air temperature exceeds the upper limit set in the next field, then the gradient entered in the 'Temperature Gradient Upper Bound' field is used. Similarly if the mean zone air temperature is below the value set in the 'Lower Temperature' field, then the gradient entered in the 'Temperature Gradient Lower Bound' is used. For mean zone air temperatures that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.

**ZoneAndOutdoorTemperatureDifference:** This key directs the program to interpolate between upper and lower values of the vertical gradient based on the difference between the outdoor environment and the mean zone air temperature. If the temperature difference exceeds the upper limit set in the next field, then the gradient entered in the 'Temperature Gradient Upper Bound' field is used. Similarly if the temperature difference is below the value set in the 'Lower Temperature' field, then the gradient entered in the 'Temperature Gradient Lower Bound' is used. For temperature differences that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.

**SensibleCoolingLoad:** This key directs the program to interpolate between upper and lower values of the vertical gradient based on the sensible cooling load. If the cooling load exceeds the upper limit set in the next field, then the gradient entered in the 'Temperature Gradient Upper Bound' field is used. Similarly if the cooling load is below the value set in the 'Lower Temperature' field, then the gradient entered in the 'Temperature Gradient Lower Bound' is used. For cooling loads that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.

**SensibleHeatingLoad:** This key directs the program to interpolate between upper and lower values of the vertical gradient based on the sensible heating load. If the heating load exceeds the upper limit set in the next field, then the gradient entered in the 'Temperature Gradient Upper Bound' field is used. Similarly if the heating load is below the value set in the 'Lower Temperature' field, then the gradient entered in the 'Temperature Gradient Lower Bound' is used. For heating loads that lie between the upper and lower bounds, the gradient is determined by linear interpolation between the two.

#### 1.12.5.9 Field: Upper Temperature Bound

This field is used to enter the upper bound on temperature values in Celsius. It is required for the interpolation modes based on temperature.

#### 1.12.5.10 Field: Lower Temperature Bound

This field is used to enter the lower bound on temperature values in Celsius. It is required for the interpolation modes based on temperature.

#### 1.12.5.11 Field: Upper Heat Rate Bound

This field is used to enter the upper bound on heat rate values. It is required for the interpolation modes based on load. Both heating and cooling loads are entered as positive numbers (in watts).

#### 1.12.5.12 Field: Lower Heat Rate Bound

This field is used to enter the lower bound on heat rate values. It is required for the interpolation modes based on load. Both heating and cooling loads are entered as positive numbers (in watts).

An example of this object follows. This pattern will apply no gradient (effectively the mixing model) if zone air temperatures are 22.5 C or lower. It will apply a gradient of 1 K/m if zone temperatures are 26.0 C or higher. For zone air temperatures between 22.5 and 26.0 it will determine the gradient by linear interpolation and use a gradient between 0.0 and 1.0 K/m depending on where the zone air temperature is in the range.

### 1.12.6 RoomAir:TemperaturePattern:NondimensionalHeight

This object defines a distribution pattern for air temperatures relative to the current mean air temperature as a function of height. The height, referred to as Zeta, is non-dimensional by normalizing with the zone ceiling height. (The actual zone ceiling height can be explicitly entered in the 'Zone' object but if not it is calculated by EnergyPlus from the surfaces attached to the zone.) The temperature differences are not non-dimensional and remain in units of degrees Celsius.

An example of a vertical temperature pattern is shown in the figure below. The pattern itself is treated as a piecewise, linear model of air temperature as a function of height. This Zeta-DeltaTai curve, or lookup table, is then mapped to surfaces defined elsewhere in the file. The centroid of each surface and zone ceiling height are used to automatically assign Zeta values within the program. The zone named in the referencing RoomAir:TemperaturePattern:UserDefined object is used to determine which surfaces will be associated with the pattern when it is applied. A single pattern object can be reused for multiple zones and times.

In addition to the vertical temperature pattern there are three other parameters included in the pattern that are important. The first two might affect how the air system conditioning the room is operated. The first describes the temperature difference between the mean air temperature and the point where the sensor of a drybulb thermostat is situated. The second describes the temperature difference between the mean and the point where system air is being extracted from the zone. This is considered important because the changes in temperature difference between supply and return can affect how an air system is controlled to meet the loads. The third parameter can affect the zone air heat balance by altering the temperature of the air leaving the zone through exhaust fans.

Figure 44. Example of a Vertical Air Temperature Pattern

#### 1.12.6.1 Field: Name

This field provides a unique name for this object.

#### 1.12.6.2 Field: Control Integer for Pattern Control Schedule Name

This field should contain an integer value that is unique among all other RoomAir Temperature Pattern objects. The value used here needs to be in the Pattern Control Schedule for those times when this pattern is to be used for the Room Air Temperature Distribution.

#### 1.12.6.3 Field: Thermostat Offset

This field specifies the temperature difference between where the thermostat is situated and the mean air temperature.

#### 1.12.6.4 Field: Return Air Offset

This field specifies the temperature difference between the air leaving the zone and returning to the air system and the mean air temperature.

#### 1.12.6.5 Field: Exhaust Air Offset

This field specifies the temperature difference between the air leaving the zone and being exhausted out of the building and the mean air temperature.

#### 1.12.6.6 Field Set Zeta and Temperature Difference

The remaining fields contain pairs of values that define a lookup table for the temperature pattern in the vertical direction. The first value is Zeta and the second value is DeltaTai. This object is extensible, by duplicating the last two fields and revising the IDD – note that you will have to replace “inner” semi-colons with commas.

### 1.12.6.7 Field: Pair <#> Zeta non-dimensional Height

Zeta is the normalized height and should be a fractional value from 0.0 to 1.0. A value of 0.0 corresponds to the floor and a value of 1.0 corresponds to the ceiling. The Zeta values need to be in increasing value.

### 1.12.6.8 Field: Pair <#> Delta Adjacent Air Temperature

$\Delta T_{ai}$  is the temperature difference between the air temperature at the associated Zeta ( $T_i$ ) and the mean air temperature and is given in degrees Celsius.

An example of this object corresponding to the figure above is:

```
RoomAir:TemperaturePattern:NondimensionalHeight,  
  Rough UFAD Approx , ! Name  
  3001 , ! Control Integer for Pattern Control Schedule  
    ! note reference this entry in Schedule

  0.95, 1.44; ! pair 11 (Zeta , DeltaTai)
```

## 1.12.7 RoomAir:TemperaturePattern:SurfaceMapping

This object defines a distribution pattern for the air temperatures adjacent to individual surfaces. This object uses the specific names of individual surfaces defined elsewhere in the model. This pattern allows controlling the adjacent air temperature on a surface-by-surface basis rather than by height. This allows modeling different adjacent air temperatures on the opposite sides of the zone.

In addition to the surface mappings there are three other parameters included in the pattern that are important. The first two might affect how the air system conditioning the room is operated. The first describes the temperature difference between the mean air temperature and the point where the sensor of a drybulb thermostat is situated. The second describes the temperature difference between the mean and the point where system air is being extracted from the zone. This is considered important because the changes in temperature difference between supply and return can affect how an air system is controlled to meet the loads. The third parameter can affect the zone air heat balance by altering the temperature of the air leaving the zone through exhaust fans.

### 1.12.7.1 Field: Name

This field provides a unique name for this object.

### 1.12.7.2 Field: Control Integer for Pattern Control Schedule Name

This field should contain an integer value that is unique among all other RoomAir Temperature Pattern objects. The value used here needs to be in the Pattern Control Schedule for those times when this pattern is to be used for the RoomAir Temperature Distribution.

### 1.12.7.3 Field: Thermostat Offset

This field specifies the temperature difference between where the thermostat is situated and the mean air temperature.

### 1.12.7.4 Field: Return Air Offset

This field specifies the temperature difference between the air leaving the zone and returning to the air system and the mean air temperature.

### 1.12.7.5 Field: Exhaust Air Offset

This field specifies the temperature difference between the air leaving the zone and being exhausted out of the building and the mean air temperature.

### 1.12.7.6 Field Set: Surface Name, Temperature Difference

### 1.12.7.7 Fields (6 and on): Pairs of Surface Names and Temperature Differences

The remaining fields contain pairs that define a lookup table for the temperature pattern on a surface-by-surface basis. This object is extensible, by duplicating the last two fields and revising the IDD – note that you will have to replace “inner” semi-colons with commas.

### 1.12.7.8 Field: Surface Name Pair <#>

The name of a surface defined elsewhere in the input file.

### 1.12.7.9 Field: Delta Adjacent Air Temperature Pair <#>

$\Delta T_{ai}$  is the temperature difference between the air temperature adjacent to the associated surface ( $T_{s,i}$ ) and the mean air temperature and is given in degrees Celsius.

An example of this object, which might be used to elevate temperatures near west windows in the afternoon, is:

```
RoomAir:TemperaturePattern:SurfaceMapping,
  GroundFloor SW Corner Hot Near West Wall, ! Name
  4001, ! Control Integer for Pattern Control Schedule Name
  0.0, ! Thermostat Offset(Temp at thermostat- Mean Air Temp)
  0.0, ! Return Air Offset deg C
  0.0, ! Exhaust Air Offset
  ZN1_SW_1:W_ExtWall:1, 0.8, ! pair 1 (Surface Name , DeltaTai)
  ZN1_SW_1:W_ExtWall:2, 0.9, ! pair 2 (Surface Name , DeltaTai)
  ZN1_SW_1:W_ExtWall:3, 1.0, ! pair 3 (Surface Name , DeltaTai)
  ZN1_SW_1:W_ExtWall:4, 1.1, ! pair 4 (Surface Name , DeltaTai)
  ZN1_SW_1:W_ExtWall:5, 1.3, ! pair 5 (Surface Name , DeltaTai)
  ZN1_SW_1:W_ExtWall:6, 1.5, ! pair 6 (Surface Name , DeltaTai)
  ZN1_SW_1:W_ExtWall:7, 1.7, ! pair 7 (Surface Name , DeltaTai)
  ZN1_SW_1:W_ExtWall:8, 2.1, ! pair 8 (Surface Name , DeltaTai)
  ZN1_SW_1:W_ExtWall:9, 2.4 ; ! pair 8 (Surface Name , DeltaTai)
```

## 1.12.8 RoomAir:Node

The RoomAir:Node object is used to define air nodes for a nodal air model. The number of air node objects that need to be specified depends on the nodal air model selected. (However, currently only the Mundt model uses this object). In order to use the Mundt model, the user must specify six or more RoomAir:Node objects of different types for each zone. The exact number of RoomAir:Node in the model will vary based on the resolution of walls. If walls (heat transfer surfaces) are split into separate segments in the vertical direction, then more air nodes of type 'MundtRoom' will be useful. At a minimum, for the Mundt model RoomAir Nodes of the following type are required: 'Inlet', 'Floor', 'Control', 'Ceiling', 'MundtRoom', and 'Return.'

### 1.12.8.1 Field: Name

This alpha field is a name for the air node. It should be unique and is used as an identifier

### 1.12.8.2 Field: Node Type

This alpha field indicates the type of this air node. The following explains options available for use with the Mundt nodal air model.

**Inlet** is specified for the air node located where the system air enters the zone.

**Floor** is specified for the air node located near the floor.

**Control** is specified for the air node located near the thermostat.

**Ceiling** is specified for the air node located near the ceiling.

**MundtRoom** is specified for the air node located adjacent to the wall(s).

**Return** is specified for the air node located where the system air leaves the zone.

### 1.12.8.3 Field: Zone Name

This field indicates the name of the zone (Ref: Zone) that this air node belongs to. This should be the unique name of a zone object defined elsewhere in the input file.

### 1.12.8.4 Field: Height of Nodal Control Volume Center

This numeric field indicates the height of the air node center. Air models such as the Mundt model compute the air temperature as a function of height and the value entered here will be used to determine a result for this node. The value should be specified in meters and relative to the floor of the zone.

### 1.12.8.5 Field: Surface <#> Name

These remaining alpha fields indicate the names of the surfaces (Ref: Surface) that are interacting convectively with this air node. This field is optional and related to the previous field. Currently, at most 20 surfaces are allowed to interact with a single air node. Only those nodes that interact with the inside faces of surfaces need to specify surface names. Each surface should couple to no more than 1 node.

An IDF example:

```
RoomAir:Node,
```

```

WESTZN:FLOORAIR,    !- Node Name
Floor,             !- Node Type
WEST ZONE,         !- Name of Zone to Which the Air Node Belongs
0.1,              !- Height of Nodal Control Volume Center {m}
WESTZN:FLOOR:LEFF, !- surface name
WESTZN:FLOOR:RIGHT; !- surface name

```

### 1.12.9 RoomAirSettings:OneNodeDisplacementVentilation

The RoomAirSettings:OneNodeDisplacementVentilation object is used to specify additional input parameters required by the Mundt model that are not available in other input objects in EnergyPlus. A single object will be used for the zone.

#### 1.12.9.1 Field: Zone Name

This alpha field indicates the name of the zone (Ref: Zone) for the required input parameters as specified in the following fields.

#### 1.12.9.2 Field: Fraction of Convective Internal Loads Added to Floor Air

This numeric field indicates what fraction of the convective part of the internal gains is added to the air near the floor in the zone specified.

#### 1.12.9.3 Field: Fraction of Infiltration Internal Loads Added to Floor Air

This numeric field indicates what fraction of the infiltration air enters near the floor in the zone specified.

An IDF example:

```

RoomAirSettings:OneNodeDisplacementVentilation,
WEST ZONE,    !- Zone Name
0.1,         !- Fraction of internal loads from the convective Floor Air
0.1;         !- Fraction of internal loads from the Infiltration Air

```

### 1.12.10 RoomAirSettings:ThreeNodeDisplacementVentilation

This model is applicable to spaces that are served by a low velocity floor-level displacement ventilation air distribution system. Furthermore, the dominant sources of heat gain should be from people and other localized sources located in the occupied part of the room. The model should be used with caution in zones which have large heat gains or losses through exterior walls or windows or which have considerable direct solar gain. The model predicts three temperatures in the room:

- A foot level temperature ( $T_{\text{FLOOR}}$ ). The floor region is 0.2 meters deep and  $T_{\text{FLOOR}}$  represents the temperature at the mid-point of the region.
- An occupied subzone temperature ( $T_{\text{OC}}$ ), representing the temperature in the region between the floor layer and the upper, mixed layer.
- An upper node representing the mixed-layer/outflow temperature ( $T_{\text{MX}}$ ) essential for overall energy budget calculations and for modeling comfort effects of the upper layer temperature.

Figure 45. Schematic representation of the three temperature points and temperature gradients

The following fields are used to define an instance of the 'UCSD Displacement Ventilation Model Controls' object.

**1.12.10.1 Field: Zone Name**

This field provides the unique name of a zone described elsewhere in the file. A single instance of the 'UCSD Displacement Ventilation Model Controls' object is needed for each zone that is to be modeled using this method.

**1.12.10.2 Field: Gain Distribution Schedule Name**

This field specifies the unique name of schedule defined elsewhere in the input file. The schedule values are the fractions of the convective portion of the internal gains in the occupied subzone that remain in the occupied subzone. The remainder of the convective portion of the internal gains in the occupied subzone enters the plumes and is carried to the upper subzone. The types of internal gains that are assumed to be located in the occupied subzone are:

- people
- task lights
- electric equipment
- gas equipment
- hot water equipment
- steam equipment
- other equipment
- baseboard heat

Types of internal gains that are assumed to be in the upper subzone are:

- general lights

- tubular daylighting devices
- high temperature radiant heaters

The schedule values should be between 0 and 1. A value of 1 means that all the convection gains from equipment, task lights and people are dispersed in the lower occupied subzone. Conversely a value of 0 puts all the lower subzone convective gains into the plumes rising into the upper well-mixed subzone.

#### 1.12.10.3 Field: Number of Plumes per Occupant

This field specifies number of plumes per occupant. Plumes are associated with localized sources of convective heat gain from people and equipment. For example, a value of 2.0 would be used if each occupant has a computer that generates a separate plume that does not merge with the plume from the occupant in the lower, occupied, subzone.

#### 1.12.10.4 Field: Thermostat Height

This field is the height in meters of the thermostat/temperature control sensor above the floor.

#### 1.12.10.5 Field: Comfort Height

The height in meters above the floor at which air temperature is calculated for comfort purposes. The air temperature at this height is used in calculating the available measures of comfort: Fanger, Pierce or KSU. The default is 1.1 meters.

#### 1.12.10.6 Field: Temperature Difference Threshold for Reporting

This field specifies a minimum temperature difference between the upper mixed subzone and the occupied subzone that will be used to trigger whether or not the displacement ventilation auxiliary outputs will be calculated. These outputs are *Room Air Zone Transition Height*, *Room Air Zone Recommended Minimum Flow Fraction*, *Room Air Zone Average Temperature Gradient* and *Room Air Zone Maximum Temperature Gradient*. They are set to negative values when the temperature difference is less than the threshold and the output *Room Air Zone Is Mixed Status* is set to 1.

The value should be greater than or equal to zero and is in units of degrees Centigrade. The default value is 0.4 degrees C.

An example input:

```
RoomAirSettings:ThreeNodeDisplacementVentilation,
  ZONE ONE,  !- Zone Name
  Constant - .2,  !- Gain Distribution Schedule Name
  1,  !- Number of Plumes per Occupant
  ,  !- Thermostat Height
  ,  !- Comfort Height
  .3;  !- Temp. Difference Threshold for Displacement Ventilation
```

### 1.12.11 RoomAirSettings:CrossVentilation

The UCSD Cross Ventilation Room Air Model provides a simple model for heat transfer and temperature prediction in cross ventilated rooms. Cross Ventilation (CV) is common in many naturally ventilated buildings, with air flowing through windows, open doorways and large internal apertures across rooms and corridors in the building.

The CV model is used in EnergyPlus in the context of natural ventilation simulations using the AirflowNetwork airflow prediction model. Typical CV room flows are characterized by two clearly distinguishable flow regions that have different airflow velocities and temperature:

- Jet regions in front of the inflow windows
- Recirculation regions in the portions of the room that are not directly in front of the windows.

Each inflow aperture has one jet region while the recirculation regions are treated as a whole, with a single temperature and characteristic velocity. The default EnergyPlus perfectly mixed single temperature node room air approach is not suitable for these partially mixed flows. The proposed CV model uses multiple nodes with distinct air temperature and airflow velocity (one node for the recirculations plus one additional node for each inflow aperture).

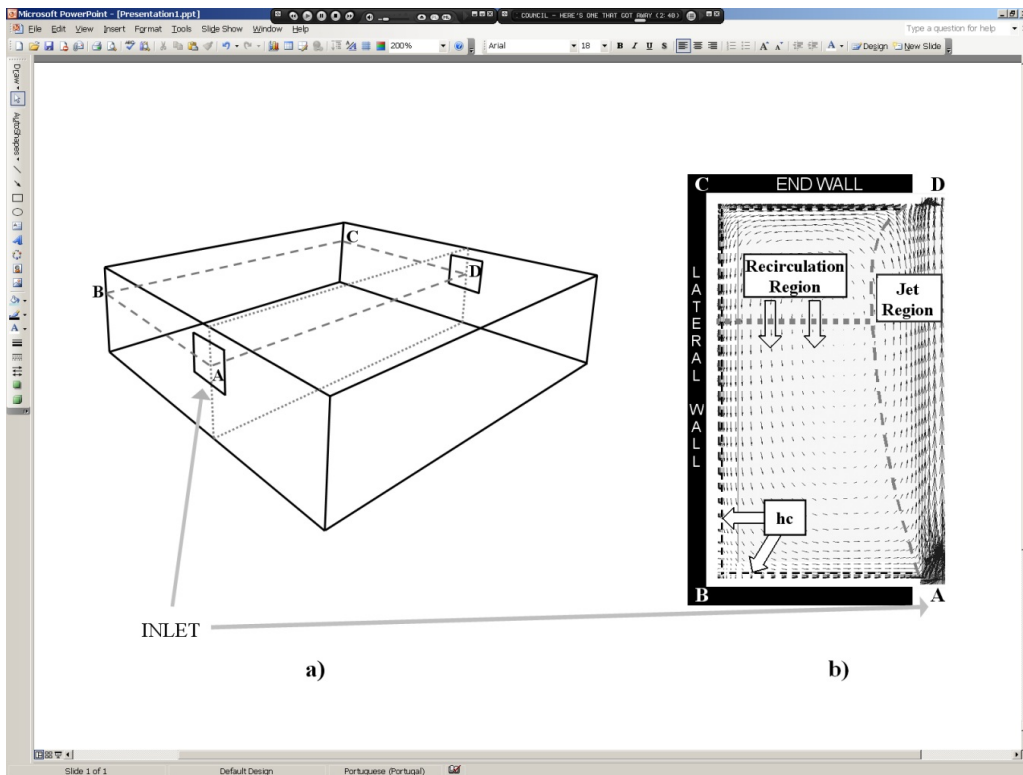

Figure 46. Schematic representation of room air geometry a) schematic representation of a room geometry that generates cross ventilation airflow. b) the proposed model distinguishes two regions in the flow: jet and recirculation (shown here in a CFD simulation of one half of a symmetrical room).

Figure 47. Schematic top view –possible airflow patterns in cross-ventilation.

The following fields are used to define an instance of the 'UCSD Cross Ventilation Model Controls' object.

#### 1.12.11.1 Field: Zone Name

This field provides the name of the zone to which this object applies. A single instance of the 'UCSD Cross Ventilation Model Controls' object is needed for each zone modeled using this method.

#### 1.12.11.2 Field: Gain Distribution Schedule Name

This field specifies the unique name of schedule defined elsewhere in the input file. The schedule values define the fractions of the convective portion of the internal gains in the jet and recirculation regions.

The schedule values should be between 0 and 1. A value of 1 means that all the convective gains are dispersed in the jet region. Conversely a value of 0 puts all the convective gains into the recirculation region.

### 1.12.11.3 Field: Airflow Region Used for Thermal Comfort Evaluation

Required field whenever thermal comfort is predicted. Defines air temperature and mean airflow velocity that will be used in the Fanger model. Conditions must refer to one of the two regions defined in the model: jet or recirculation.

Possible choices: Jet or Recirculation.

## 1.12.12 CrossVentilation Model Outputs

- Zone,Average,Room Air Zone Jet Region Temperature [C]
- Zone,Average,Room Air Zone Recirculation Region Temperature [C]
- Zone,Average,Room Air Zone Jet Region Average Air Velocity [m/s]
- Zone,Average,Room Air Zone Recirculation Region Average Air Velocity [m/s]
- Zone,Average,Room Air Window Jet Region Average Air Velocity [m/s] Zone,Average,Room Air Zone Recirculation and Inflow Rate Ratio []
- Zone,Average,Room Air Zone Inflow Opening Area [m2]
- Zone,Average,Room Air Zone Room Length [m]
- Zone,Average,Room Air Zone Is Mixing Status []
- Zone,Average,Room Air Zone Is Recirculating Status []

### 1.12.12.1 Room Air Zone Jet Region Temperature [C]

Average air temperature in the jet region of the flow in degrees C. If there is more than one inflow window this output will be the inflow-area-weighted average of the jet region temperature.

### 1.12.12.2 Room Air Zone Recirculation Region Temperature [C]

Average air temperature in the recirculation region of the flow in degrees C.

### 1.12.12.3 Room Air Zone Jet Region Average Air Velocity [m/s]

Average airflow velocity in the jet region of the flow in meters per second. If there is more than one inflow window this output will be the inflow area weighted area of the jet inflow velocities.

### 1.12.12.4 Room Air Window Jet Region Average Air Velocity [m/s]

Average airflow velocity in the jet region in front of the window, in meters per second.

### 1.12.12.5 Room Air Zone Recirculation Region Average Air Velocity [m/s]

Average airflow velocity in the recirculation region of the flow in meters per second.

### 1.12.12.6 Room Air Zone Recirculation and Inflow Rate Ratio []

Ratio between airflow rate in the recirculation regions and the total inflow rate, non-dimensional.

### 1.12.12.7 Room Air Zone Inflow Opening Area [m2]

Area of the inflow aperture in square meters. This area can change due to variation in wind direction (as inflow aperture changes) or variations in the opening schedule.

### 1.12.12.8 Room Air Zone Room Length [m]

Length of the room along the cross ventilation direction, in meters.

### 1.12.12.9 Room Air Zone Is Mixing Status []

An integer flag that indicates whether the zone is mixed (single node well-mixed zone model used) or significant momentum conservation is occurring (UCSD CV model used). The value 1 means well-mixed; 0 means cross ventilation is present. Transition to mixed flow can occur due to three mechanism: reduction in inflow velocity, reduction in inflow aperture area and dominance of buoyancy effects. A value of 1 is yes, a value of 0 is no.

#### 1.12.12.10 Room Air Zone Is Recirculating Status []

An integer flag that indicates whether recirculations are present in the flow. A cross ventilation flow does not have recirculations whenever the inflow area is similar to the room cross section area (such as airflow in a typical corridor). A value of 1 is yes, a value of 0 is no.

#### 1.12.13 RoomAirSettings:UnderFloorAirDistributionInterior

This model is applicable to interior spaces that are served by an underfloor air distribution system. The dominant sources of heat gain should be from people, equipment, and other localized sources located in the occupied part of the room. The model should be used with caution in zones which have large heat gains or losses through exterior walls or windows or which have considerable direct solar gain. The model predicts two temperatures in the room:

- An occupied subzone temperature ( $T_{OC}$ ), representing the temperature in the region between the floor and the boundary of the upper subzone..
- An upper subzone temperature ( $T_{MX}$ ) essential for overall energy budget calculations and for modeling comfort effects of the upper layer temperature.

The following fields are used to define an instance of the 'UCSD UFAD Interior Model Controls' object.

##### 1.12.13.1 Field: Zone Name

This field provides the unique name of a zone described elsewhere in the file. A single instance of the 'RoomAirSettings:UnderFloorAirDistributionInterior' object is needed for each zone that is to be modeled using this method.

##### 1.12.13.2 Field: Number of Diffusers

The total number of diffusers in this zone. This field can allowed to Autocalculate (in which case it is set to the design occupancy level; i.e., number of people). If the design occupancy is low or zero but there are still heat sources that could generate buoyancy driven plumes, the user should input a value based on the design supply air flow rate of the zone and the design flow rate of an individual diffuser. In the absence of any other information, divide the zone area by 100 ft<sup>2</sup>. The default for this field is Autocalculate.

##### 1.12.13.3 Field: Power per Plume

The power in watts incorporated in a buoyancy driven thermal plume. Normally we assume all the loads of a workstation create a single plume so that this represents the convective heat gain from a workstation – 1 person, 1 computer terminal, plus any task lighting. A typical value would be 220 watts. However, the model assumes an "equivalent" plume derived from the zone extraction rate normalized to the number of workstations/occupants. This field should be allowed to default – the program will calculate a value based upon the occupancy and the extraction rate. The default is Autocalculate.

##### 1.12.13.4 Field: Design Effective Area of Diffuser

This is the design air flow opening area in square meters of a single diffuser. The default value depends on the diffuser type. For swirl diffusers it is 0.075 m<sup>2</sup> for variable area diffusers 0.035 m<sup>2</sup>, for horizontal swirl diffusers 0.006 m<sup>2</sup>, and for linear bar grilles 0.03 m<sup>2</sup>. The default is *Autocalculate*..

##### 1.12.13.5 Field: Diffuser Slot Angle from Vertical

This input describes the angle at which air emerges from the diffusers. It should be the angle in degrees between the vertical and the diffuser slots. The defaults depend on the diffuser type: for swirl diffusers it is 28 degrees, for variable area diffusers 45 degrees, for DV diffusers 73 degrees, and for linear bar grilles 15 degrees.

##### 1.12.13.6 Field: Thermostat Height

This field is the height in meters of the thermostat/temperature control sensor above the floor. The default is 1.2 meters.

##### 1.12.13.7 Field: Comfort Height

The height in meters above the floor at which air temperature is calculated for comfort purposes. The air temperature at this height is used in calculating the available measures of comfort: Fanger, Pierce or KSU. The default is 1.1 meters.

##### 1.12.13.8 Field: Temperature Difference Threshold for Reporting

This field specifies a minimum temperature difference between the upper subzone and the occupied subzone that will be used to trigger whether or not the UFAD auxiliary outputs will be calculated. These outputs are *Room Air Zone Transition Height* and *Room Air Zone Average Temperature Gradient*. They are set to zero when the temperature difference is less than the threshold and the output *Room Air Zone Is Mixed Status* is set to 1.

The value should be greater than or equal to zero and is in units of degrees Centigrade. The default value is 0.4 degrees C.

### 1.12.13.9 Field: Diffuser Type

The choices for this alpha field are **Swirl** | **VariableArea** | **HorizontalSwirl** | **LinearBarGrille** | **Custom**. The swirl and displacement diffusers are fixed area diffusers. The variable area diffusers maintain an approximately constant exit velocity. Linear bar grilles are normally used in exterior zones and are fixed area diffusers. Custom is used to signify that the user intends to input the coefficients A – E (see below) rather than let the program set the coefficients based on diffuser type. The default is *Swirl*.

### 1.12.13.10 Field: Transition Height

An optional field to allow the user to specify the transition height (meters above floor) rather than have the program calculate it. The default is 1.7 meters.

### 1.12.13.11 Field: Coefficient A

The coefficient A in the formula:  $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$ . Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

### 1.12.13.12 Field: Coefficient B

The coefficient B in the formula:  $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$ . Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

### 1.12.13.13 Field: Coefficient C

The coefficient C in the formula:  $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$ . Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

### 1.12.13.14 Field: Coefficient D

The coefficient D in the formula:  $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$ . Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

### 1.12.13.15 Field: Coefficient E

The coefficient E in the formula:  $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$ . Gamma is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

An example input is:

```

```

## 1.12.14 RoomAirSettings:UnderFloorAirDistributionExterior

This model is applicable to exterior spaces that are served by an underfloor air distribution system. The dominant sources of heat gain should be from people, equipment, and other localized sources located in the occupied part of the room, as well as convective gain coming from a warm window. The model predicts two temperatures in the room:

- An occupied subzone temperature ( $T_{OC}$ ), representing the temperature in the region between the floor and the boundary of the upper subzone..
- An upper subzone temperature ( $T_{MX}$ ) essential for overall energy budget calculations and for modeling comfort effects of the upper layer temperature.

The following fields are used to define an instance of the 'UCSD UFAD Exterior Model Controls' object.

#### 1.12.14.1 Field: Zone Name

This field provides the unique name of a zone described elsewhere in the file. A single instance of the 'RoomAirSettings:UnderFloorAirDistributionExterior' object is needed for each zone that is to be modeled using this method.

#### 1.12.14.2 Field: Number of Diffusers

**1.12.14.3 The total number of diffusers in this zone. This field can allowed to Autocalculate (in which case it is set to the design occupancy level; i.e., number of people). If the design occupancy is low or zero but there are still heat sources that could generate buoyancy driven plumes, the user should input a value based on the design supply air flow rate of the zone and the design flow rate of an individual diffuser. In the absence of any other information, divide the zone area by 100 ft<sup>2</sup>. The default for this field is Autocalculate.**

#### 1.12.14.4 Field: Power per Plume

**1.12.14.5 The power in watts incorporated in a buoyancy driven thermal plume. Normally we assume all the loads of a workstation create a single plume so that this represents the convective heat gain from a workstation – 1 person, 1 computer terminal, plus any task lighting. A typical value would be 220 watts. However, the model assumes an “equivalent” plume derived from the zone extraction rate normalized to the number of workstations/occupants. This field should be allowed to default – the program will calculate a value based upon the occupancy and the extraction rate. The default is Autocalculate.**

#### 1.12.14.6 Field: Design Effective Area of Diffuser

This is the design air flow opening area in square meters of a single diffuser. The default value depends on the diffuser type. For swirl diffusers it is 0.075 m<sup>2</sup> for variable area diffusers 0.035 m<sup>2</sup>, for horizontal swirl diffusers 0.006 m<sup>2</sup>, and for linear bar grilles 0.03 m<sup>2</sup>. The default is *Autocalculate*..

#### 1.12.14.7 Field: Diffuser Slot Angle from Vertical

This input describes the angle at which air emerges from the diffusers. It should be the angle in degrees between the vertical and the diffuser slots. The defaults depend on the diffuser type: for swirl diffusers it is 28 degrees, for variable area diffusers 45 degrees, for DV diffusers 73 degrees, and for linear bar grilles 15 degrees.

#### 1.12.14.8 Field: Thermostat Height

This field is the height in meters of the thermostat/temperature control sensor above the floor. The default is 1.2 meters.

#### 1.12.14.9 Field: Comfort Height

The height in meters above the floor at which air temperature is calculated for comfort purposes. The air temperature at this height is used in calculating the available measures of comfort: Fanger, Pierce or KSU. The default is 1.1 meters.

#### 1.12.14.10 Field: Temperature Difference Threshold for Reporting

This field specifies a minimum temperature difference between the upper subzone and the occupied subzone that will be used to trigger whether or not the UFAD auxiliary outputs will be calculated. These outputs are *Room Air Zone Transition Height* and *Room Air Zone Average Temperature Gradient*. They are set to zero when the temperature difference is less than the threshold and the output *Room Air Zone Is Mixed Status* is set to 1.

The value should be greater than or equal to zero and is in units of degrees Centigrade. The default value is 0.4 degrees C.

The value should be greater than or equal to zero and is in units of degrees Centigrade. The default value is 0.4 degrees C.

#### 1.12.14.11 Field: Diffuser Type

The choices for this alpha field are **Swirl | VariableArea | HorizontalSwirl | LinearBarGrille | Custom**. The swirl and displacement diffusers are fixed area diffusers. The variable area diffusers maintain an approximately constant exit velocity. Linear bar grilles are normally used in exterior zones and are fixed area diffusers. Custom is used to signify that the user intends to input the coefficients A – E (see below) rather than let the program set the coefficients based on diffuser type. The default is *Swirl*.

#### 1.12.14.12 Field: Transition Height

An optional field to allow the user to specify the transition height (meters above floor) rather than have the program calculate it. The default is 1.7 meters.

#### 1.12.14.13 Field: Coefficient A

The coefficient A in the formula:  $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$ .  $\Gamma$  is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

#### 1.12.14.14 Field: Coefficient B

The coefficient B in the formula:  $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$ .  $\Gamma$  is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

#### 1.12.14.15 Field: Coefficient C

The coefficient C in the formula:  $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$ .  $\Gamma$  is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

#### 1.12.14.16 Field: Coefficient D

The coefficient D in the formula:  $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$ .  $\Gamma$  is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

#### 1.12.14.17 Field: Coefficient E

The coefficient E in the formula:  $Kc = A \cdot \Gamma^B + C + D \cdot \Gamma + E \cdot \Gamma^2$ .  $\Gamma$  is a variable that characterizes the amount of stratification in a UFAD zone. Kc is the fraction of the total internal convective heat gain that is assigned to the lower (occupied) subzone. The coefficients in the formula are defaulted based upon diffuser type. A user would normally allow this field to default. The default is *autocalculate*.

An example input is:

```
RoomAirSettings:UnderFloorAirDistributionExterior,
SPACE1-1,                !- Zone Name
Autocalculate,           !- Number of Diffusers per Zone

### 1.12.15 RoomAirflowNetwork Model

This model simulates a thermal zone using a network approach by assuming intra-zone nodes connected by user-defined patterns of airflows. The new model also allows users to specify a node to be connected to surfaces to have convective heat transfer between surfaces and the node, portion of internal gains and supply air and return air fractions from zone equipment. The model requires following objects to work together:

```
RoomAirSettings:AirflowNetwork
RoomAir:Node:AirflowNetwork
RoomAir:Node:AirflowNetwork:AdjacentSurfaceList
RoomAir:Node:AirflowNetwork:InternalGains
RoomAir:Node:AirflowNetwork:HVACEquipment
AirflowNetwork:Intrazone:Node
AirflowNetwork:Intrazone:Linkage
```

The first *five objects* are described below. The last two objects are described in the Airflow Network Model section.

#### 1.12.16 RoomAirSettings:AirflowNetwork

This object provides inputs in a thermal zone needed for the RoomAirflowNetwork model. The inputs specify a thermal zone and a list of RoomAir nodes. The object gives a summary of the model configuration in a zone.

##### 1.12.16.1 Field: Name

This is a unique character string associated with this instance of the RoomAirSettings:AirflowNetwork object.

### 1.12.16.2 Field: Zone Name

The name of the EnergyPlus thermal zone corresponding to the RoomAir model zone.

### 1.12.16.3 Field: Control Point RoomAir:Node Name

This is the name of a RoomAir:Node:AirflowNetwork object that contains the sensor for zone HVAC controls. The conditions at this node will be used for thermostatic, humidistatic, or comfort based control decisions. The zone node defined in a Zone object is required.

### 1.12.16.4 Field: RoomAir:Node:AirflowNetwork x Name

The name of a RoomAir:Node:AirflowNetwork object defined elsewhere. This node will receive the fraction of internal gains, and HVAC equipment, and a list of surface names exposed to this node with convective heat transfer.

An IDF example input is:

```
RoomAirSettings:AirflowNetwork,
  NORTH_ZONE,      !- Name
  NORTH_ZONE,      !- Zone Name
  RoomAir Schedule, !- Availability Schedule Name
  NORTH_ZONE,      !- Control Point RoomAir:Node Name
  LeftUpper,       !- RoomAir:Node:AirflowNetwork 1 Name
  CentralUpper,    !- RoomAir:Node:AirflowNetwork 2 Name
  NORTH_ZONE,      !- RoomAir:Node:AirflowNetwork 3 Name
  LeftMiddle,      !- RoomAir:Node:AirflowNetwork 4 Name
  LeftLower,       !- RoomAir:Node:AirflowNetwork 5 Name
  CentralLower;    !- RoomAir:Node:AirflowNetwork 6 Name
```

## 1.12.17 RoomAir:Node:AirflowNetwork

This object is used to define a node in a thermal zone. The input specifies the fraction of zone volume and provides a list of names to define fraction of internal gains, surface connection and HVAC equipment.

### 1.12.17.1 Field: Name

This is a unique character string associated with this instance of the RoomAirSettings:AirflowNetwork object.

### 1.12.17.2 Field: Zone Name

The name of the EnergyPlus thermal zone and is defined in an RoomAirSettings:AirflowNetwork object.

### 1.12.17.3 Field: Fraction of Zone Air Volume

The field specifies a fraction of the overall zone air volume that is assigned to this RoomAir:Node:AirflowNetwork object. The fraction will be used to calculate zone air storage term. See corresponding sections in Engineering Reference for its use in the node energy and moisture balance equations.

### 1.12.17.4 Field: RoomAir:Node:AirflowNetwork:AdjacentSurfaceList Name

The field specifies a name to provide a list of connected adjacent surfaces with convective heat transfer between surfaces and this particular node. When a moisture mode is assigned to surfaces, convective moisture transfer will be calculated. See corresponding sections in Engineering Reference for its use in the node energy and moisture balance equations.

### 1.12.17.5 Field: RoomAir:Node:AirflowNetwork:InternalGains Name

The field specifies a name to provide a list of internal gain objects and associated fractions assigned to this particular node. See corresponding sections in Engineering Reference for its use in the node energy and moisture balance equations.

### 1.12.17.6 Field: RoomAir:Node:AirflowNetwork:HVACEquipment Name

The field specifies a name to provide a list of HVAC equipment, including AirLoop terminals and zone equipment. See corresponding sections in Engineering Reference for its use in the node energy and moisture balance equations.

```
RoomAir:Node:AirflowNetwork,
  LeftUpper,       !- Name
  NORTH_ZONE,      !- Zone Name
  0.15,            !- Fraction of Zone Air Volume
  Surface_18_T_List, !- RoomAir:Node:AirflowNetwork:AdjacentSurfaceList Name
  LeftUpper_Gain,  !- RoomAir:Node:AirflowNetwork:InternalGains Name
  LeftUpper_HVAC;  !- RoomAir:Node:AirflowNetwork:HVACEquipment Name
```

## 1.12.18 RoomAir:Node:AirflowNetwork:AdjacentSurfaceList

This object is used to provide a list of connected adjacent surfaces with convective heat transfer between surfaces and this particular node. When a moisture mode is assigned to surfaces, convective moisture transfer will be calculated. It should be pointed out that a fraction of a surface exposed to this particular node is not allowed.

#### 1.12.18.1 Field: Name

This is a unique character string associated with this instance of the RoomAir:Node:AirflowNetwork:AdjacentSurfaceList object.

#### 1.12.18.2 Field: Surface x Name

The field specifies a surface name based on the order from 1 to 21. The maximum number of surfaces can be extensible.

```
RoomAir:Node:AirflowNetwork:AdjacentSurfaceList,  
Surface_18_T_List, !- Name  
Surface_18_T;      !- Surface 1 Name
```

#### 1.12.19 RoomAir:Node:AirflowNetwork:InternalGains

This object is used to define a list of internal gains in the same zone and associated fraction assigned to this particular node.

##### 1.12.19.1 Field: Name

This is a unique character string associated with this instance of the RoomAir:Node:AirflowNetwork:InternalGains object.

##### 1.12.19.2 Field: Internal Gain Object x Type

The field specifies an internal gain object type based on the list in the Energy+.

##### 1.12.19.3 Field: Internal Gain Object x Name

The field specifies an internal gain object name based on the list in the Energy+.

##### 1.12.19.4 Field: Fraction of Gains to Node x

The field specifies a fraction of the particular internal gain object assigned to this node.

```
RoomAir:Node:AirflowNetwork:InternalGains,  
CentralUpper_Gain,      !- Name  
People,                 !- Internal Gain Object 1 Type  
NORTH_ZONE People,     !- Internal Gain Object 1 Name  
0.15,                  !- Fraction of Gains to Node 1  
Lights,                !- Internal Gain Object 2 Type  
NORTH_ZONE Lights,     !- Internal Gain Object 2 Name  
0.15,                  !- Fraction of Gains to Node 2  
ElectricEquipment,    !- Internal Gain Object 3 Type  
NORTH_ZONE Equip,      !- Internal Gain Object 3 Name  
0.15;                  !- Fraction of Gains to Node 3
```

{Field set: 3 fields (Internal Gain Object x Type, Internal Gain Object x Name, and Fraction of Gains to Node x). are extensible.}

#### 1.12.20 RoomAir:Node:AirflowNetwork:HVACEquipment

This object is used to define a list of HVAC equipment objects in the same zone and associated fractions assigned to this particular node.

##### 1.12.20.1 Field: Name

This is a unique character string associated with this instance of the RoomAir:Node:AirflowNetwork:HVACEquipment object.

##### 1.12.20.2 Field: ZoneHVAC or Air Terminal Equipment Object Type x

The field specifies an object type of ZoneHVAC equipment or terminal type based on the list in the Energy+.idd.

##### 1.12.20.3 Field: ZoneHVAC or Air Terminal Equipment Object Name x

The field specifies the object name based on the object type defined in the previous field.

##### 1.12.20.4 Field: Fraction of Output or Supply Air from HVAC Equipment x

The field specifies a fraction of supply air from the particular equipment to this node.

##### 1.12.20.5 Field: Fraction of Input or Return Air from HVAC Equipment x

The field specifies a fraction of return air from the particular equipment to this node.

```
RoomAir:Node:AirflowNetwork:HVACEquipment,  
CentralUpper_HVAC,          !- Name  
ZoneHVAC:PackagedTerminalAirConditioner, !- ZoneHVAC or Air Terminal Equipment Object Type 1  
NORTH_ZONE PTAC,          !- ZoneHVAC or Air Terminal Equipment Object Name 1  
0.14,                      !- Fraction of Output or Supply Air from HVAC Equipment 1  
0.14;                      !- Fraction of Input or Return Air to HVAC Equipment 1
```

{Field set: 4 fields (ZoneHVAC or Air Terminal Equipment Object Type x, ZoneHVAC or Air Terminal Equipment Object Name x, Fraction of Output or Supply Air from HVAC Equipment x, and Fraction of Input or Return Air from HVAC Equipment x) are extensible.}

### 1.12.21 Room Air Model Outputs

Each room air model sets up outputs specific to that model. The effect of room air modeling is usually to adjust the adjacent air temperature along the inside surface of heat transfer surfaces. The output report "Surface Int Adjacent Air Temperature [C]" is provided for this and described under Surface Outputs.

#### 1.12.21.1 Zone Predicted Sensible Load Room Air Correction Factor

This output variable provides the value of the correction factor applied to the predicted zone loads. Predicted zone load to setpoint is (usually) used to control HVAC air systems and the presence of a room air model has an impact on the loads. The predicted loads are multiplied by the factor in this output variable. The value is always 1.0 when there is no Room Air model. When there is a Room Air model, this output shows how that model is increasing or decreasing overall zone loads experienced by the air system.

### 1.12.22 RoomAir:TemperaturePattern:TwoGradient Outputs

The user-defined air temperature pattern that interpolates between two gradients produces the following output variable.

HVAC,Average,Room Air Zone Vertical Temperature Gradient [K/m]

#### 1.12.22.1 Room Air Zone Vertical Temperature Gradient [K/m]

This output variable is the result of the interpolation performed by the user-defined roomair model using RoomAir:TemperaturePattern:TwoGradient. This is the temperature gradient in the vertical direction. The units are degrees Kelvin per meter.

### 1.12.23 Mundt Model / OneNodeDisplacementVentilation Outputs

The following output is available for the Mundt model.

Room Air Node Air Temperature [C]

#### 1.12.23.1 Room Air Node Air Temperature [C]

This output variable provides the drybulb air temperature used in, or calculated by, the Mundt model. The selection key is the name of an air node defined in a ROOMAIR Node object.

### 1.12.24 ThreeNodeDisplacementVentilation Outputs

- HVAC,Average,Room Air Zone Mixed Subzone Temperature [C]
- HVAC,Average,Room Air Zone Occupied Subzone Temperature [C]
- HVAC,Average,Room Air Zone Floor Subzone Temperature [C]
- HVAC,Average,Room Air Zone Transition Height [m]
- HVAC,Average,Room Air Zone Recommended Minimum Flow Fraction
- HVAC,Average,Room Air Zone Is Mixed Status []
- HVAC,Average,Room Air Zone Average Temperature Gradient [K/m]
- HVAC,Average,Room Air Zone Maximum Temperature Gradient [K/m]
- HVAC,Average,Room Air Zone Thermal Comfort Effective Air Temperature [C]
- HVAC,Average,Room Air Zone Thermostat Temperature [C]

#### 1.12.24.1 Room Air Zone Mixed Subzone Temperature [C]

The temperature of the upper well-mixed subzone in degrees C.

#### **1.12.24.2 Room Air Zone Occupied Subzone Temperature [C]**

The average temperature of the lower, stratified, occupied subzone in degrees C.

#### **1.12.24.3 Room Air Zone Floor Subzone Temperature [C]**

The temperature of the region near the floor in degrees C.

#### **1.12.24.4 Room Air Zone Transition Height [m]**

The height above the floor, in meters, of the boundary between the lower occupied subzone and the upper well-mixed subzone.

#### **1.12.24.5 Room Air Zone Recommended Minimum Flow Fraction []**

The ratio of the minimum recommended flow rate to the actual flow rate. Here flow rate means the sum of infiltration, ventilation, mixing and system air flow rates. The minimum flow is the flow needed to establish the boundary between the occupied and mixed subzones at 1.5 meters.

#### **1.12.24.6 Room Air Zone Is Mixed Status []**

An integer flag that indicates whether the zone is mixed (single node well-mixed zone model used) or stratified (UCSD DV model used). The value 1 means well-mixed; 0 means stratified.

#### **1.12.24.7 Room Air Zone Average Temperature Gradient [K/m]**

The temperature gradient between the middle of the floor region and the middle of the well-mixed upper subzone in degrees Kelvin per meter.

#### **1.12.24.8 Room Air Zone Maximum Temperature Gradient [K/m]**

The maximum of the temperature gradient between the middle of the floor region and the middle of the occupied subzone and the temperature gradient between the middle of the occupied subzone and the middle of the well-mixed subzone. The gradient is in degrees Kelvin per meter.

#### **1.12.24.9 Room Air Zone Thermal Comfort Effective Air Temperature [C]**

The temperature at the user specified comfort height in degrees C.

#### **1.12.24.10 Room Air Zone Thermostat Temperature [C]**

The temperature at the height of the thermostat (specified by user input) in degrees C.

### **1.12.25 CrossVentilation Model Outputs**

- Zone,Average,Room Air Zone Jet Region Temperature [C]
- Zone,Average,Room Air Zone Recirculation Region Temperature [C]
- Zone,Average,Room Air Zone Jet Region Average Air Velocity [m/s]
- Zone,Average,Room Air Zone Recirculation Region Average Air Velocity [m/s]
- Zone,Average,Room Air Zone Inflow Opening Area[m2]
- Zone,Average,Room Air Zone Room Length [m]
- Zone,Average,Room Air Zone Recirculation and Inflow Rate Ratio []
- Zone,Average,Room Air Zone Is Mixing Status []
- Zone,Average,Room Air Zone Is Recirculating Status []

#### **1.12.25.1 Room Air Zone Jet Region Temperature [C]**

Average air temperature in the jet region of the flow in degrees C.

#### **1.12.25.2 Room Air Zone Recirculation Region Temperature [C]**

Average air temperature in the recirculation region of the flow in degrees C.

#### **1.12.25.3 Room Air Zone Jet Region Average Air Velocity [m/s]**

Average airflow velocity in the jet region of the flow in meters per second.

#### 1.12.25.4 Room Air Zone Recirculation Region Average Air Velocity [m/s]

Average airflow velocity in the recirculation region of the flow in meters per second.

#### 1.12.25.5 Room Air Zone Inflow Opening Area [m<sup>2</sup>]

Area of the inflow aperture in square meters. This area can change due to variation in wind direction (as inflow aperture changes) or variations in the opening schedule.

#### 1.12.25.6 Room Air Zone Room Length [m]

Length of the room along the cross ventilation direction, in meters.

#### 1.12.25.7 Room Air Zone Recirculation and Inflow Rate Ratio []

Ratio between airflow rate in the recirculation region and inflow rate, non-dimensional.

#### 1.12.25.8 Room Air Zone Is Mixing Status []

An integer flag that indicates whether the zone is mixed (single node well-mixed zone model used) or significant momentum conservation is occurring (UCSD CV model used). The value 1 means well-mixed; 0 means cross ventilation is present. Transition to mixed flow can occur due to three mechanism: reduction in inflow velocity, reduction in inflow aperture area and dominance of buoyancy effects. A value of 1 is yes, a value of 0 is no.

#### 1.12.25.9 Room Air Zone Is Recirculating Status []

An integer flag that indicates whether recirculations are present in the flow. A cross ventilation flow does not have recirculations whenever the inflow area is similar to the room cross section area (such as airflow in a typical corridor). A value of 1 is yes, a value of 0 is no.

### 1.12.26 UnderFloorAirDistributionInterior/Exterior Model Outputs

- HVAC,Average,Room Air Zone Mixed Subzone Temperature [C]
- HVAC,Average,Room Air Zone Occupied Subzone Temperature [C]
- HVAC,Average,Room Air Zone Transition Height [m]
- HVAC,Average,Room Air Zone Is Mixed Status []
- HVAC,Average,Room Air Zone Average Temperature Gradient [K/m]
- HVAC,Average,Room Air Zone Effective Comfort Air Temperature [C]
- HVAC,Average,Room Air Zone Thermostat Temperature [C]
- HVAC,Average,Room Air Zone Transition Height Gamma Value [ ]
- HVAC,Average,Room Air Zone Plume Heat Transfer Rate [W]
- HVAC,Average,Room Air Zone Temperature Stratification Fraction []
- HVAC,Average,Room Air Zone Window Plume Heat Transfer Rate [W]

#### 1.12.26.1 Room Air Zone Mixed Subzone Temperature [C]

The temperature of the upper subzone in degrees C.

#### 1.12.26.2 Room Air Zone Occupied Subzone Temperature [C]

The temperature of the lower, occupied subzone in degrees C.

#### 1.12.26.3 Room Air Zone Transition Height [m]

The height above the floor, in meters, of the boundary between the lower occupied subzone and the upper subzone..

#### 1.12.26.4 Room Air Zone Is Mixed Status []

An integer flag that indicates whether the zone is mixed (single node well-mixed zone model used) or stratified (UCSD UFI model used). The value 1 means well-mixed; 0 means stratified.

#### 1.12.26.5 Room Air Zone Average Temperature Gradient [K/m]

The temperature gradient between the middle of the occupied subzone and the middle of the upper subzone in degrees Kelvin per meter.

#### **1.12.26.6 Room Air Zone Effective Comfort Air Temperature [C]**

The temperature at the user specified comfort height in degrees C.

#### **1.12.26.7 Room Air Zone Thermostat Temperature [C]**

The temperature at the height of the thermostat (specified by user input) in degrees C.

#### **1.12.26.8 Room Air Zone Transition Height Gamma Value []**

Value of gamma – a dimensionless “height” used in calculating the transition height. Lower values of gamma indicate increased stratification, higher values less. Generally the values should be between 2 and 30.

#### **1.12.26.9 Room Air Zone Plume Heat Transfer Rate [W]**

The heat in watts driving the plumes in the occupied subzone.

#### **1.12.26.10 Room Air Zone Window Plume Heat Transfer Rate [W]**

The convective heat gain from windows in an UnderFloorAirDistributionExterior zone.

#### **1.12.26.11 Room Air Zone Temperature Stratification Fraction []**

This output, (Phi) is a measure of temperature stratification in the space. It is the difference between the occupied subzone temperature and the supply temperature divided by difference between the return temperature and the supply temperature. Technically it is equal to  $K_c$ . As phi approaches 1, the space is fully mixed. As phi approaches 0, the space becomes fully stratified. Expressed as an equation:

$$(T_{occ} - T_{sup}) / (T_{ret} - T_{sup})$$

### **1.12.27 RoomAirflowNetwork Model Outputs**

- HVAC,Average,RoomAirflowNetwork Node Temperature [C]
- HVAC,Average,RoomAirflowNetwork Node Humidity Ratio [kgWater/kgDryAir]
- HVAC,Average,RoomAirflowNetwork Node Relative Humidity [%]
- HVAC,Average,RoomAirflowNetwork Node SumIntSensibleGain [W]
- HVAC,Average,RoomAirflowNetwork Node SumIntLatentGain [W]
- HVAC,Average,RoomAirflowNetwork Node NonAirSystemResponse [W]
- HVAC,Average,RoomAirflowNetwork Node SysDepZoneLoadsLagged [W]
- HVAC,Average,RoomAirflowNetwork Node HVAC Supply Fraction []
- HVAC,Average,RoomAirflowNetwork Node HVAC Return Fraction []

#### **1.12.27.1 RoomAirflowNetwork Node Temperature [C]**

The temperature at a Room Air Node in a zone in degrees C.

#### **1.12.27.2 HVAC,Average,RoomAirflowNetwork Node Humidity Ratio [kgWater/kgDryAir]**

The humidity ratio at a Room Air Node in a zone in kgWater/kgDryAir.

#### **1.12.27.3 RoomAirflowNetwork Node Relative Humidity [%]**

The relative humidity ratio at a Room Air Node in a zone in percent.

#### **1.12.27.4 HVAC,Average,RoomAirflowNetwork Node SumIntSensibleGain [W]**

A sum of internal sensible gains assigned to a Room Air node in a zone.

#### **1.12.27.5 HVAC,Average,RoomAirflowNetwork Node SumIntLatentGain [W]**

A sum of internal latent gains assigned to a Room Air node in a zone.

#### 1.12.27.6 HVAC,Average,RoomAirflowNetwork Node NonAirSystemResponse [W]

A sum of system convective gains, collected via NonAirSystemResponse, and assigned to a Room Air node in a zone.

#### 1.12.27.7 HVAC,Average,RoomAirflowNetwork Node SysDepZoneLoadsLagged [W]

A sum of SysDepZoneLoads saved to be added to zone heat balance at the next HVAC time step. A typical system is a zone dehumidifier.

### 1.13 Group – Internal Gains (People, Lights, Other internal zone equipment)

Not all the influence for energy consumption in the building is due to envelope and ambient conditions. This group of objects describes other internal gains that may come into play (People, Lights, Various Equipment Types).

#### 1.13.1 People

The people statement is used to model the occupant's effect on the space conditions. The following definition addresses the basic affects as well as providing information that can be used to report the thermal comfort of a group of occupants. The Fanger, Pierce Two-Node, and Kansas State University Two-Node thermal comfort models are available in EnergyPlus. A user may select any of these models for each People statement by simply adding the appropriate choice keyword after the air velocity schedule name. Thermal comfort calculations will only be made for people statements that include specific requests for these thermal comfort models. . This object also requires input of carbon dioxide generation rate based on people activity level for zone carbon dioxide simulations.

##### 1.13.1.1 Field: Name

The name of the People object. Must be unique across all People objects.

##### 1.13.1.2 Field: Zone or ZoneList Name

This field is the name of the zone (ref: Zone) or ZoneList (ref: ZoneList) and links a particular people statement to a thermal zone or set of thermal zones in the building. When the ZoneList option is used then this people definition is applied to each of the zones in the zone list effecting a global definition for the number of people in the zone. The Zonelist option can be used effectively with the people/area and area/person options of the Number of People Calculation Method.

The name of the actual people object becomes <Zone Name> <People Object Name> and should be less than the standard length (100 characters) for a name field. If it is greater than this standard length, it may be difficult to specify in output reporting as it will be truncated. A warning will be shown if the generated name is greater than 100 characters. If it duplicates another such concatenated name, there will be a severe error and terminate the run.

##### 1.13.1.3 Field: Number of People Schedule Name

This field is the name of the schedule (ref: Schedules) that modifies the number of people parameter (see Number of People Calculation Method and related fields). The schedule values can be any positive number. The actual number of people in a zone as defined by this statement is the product of the number of people field and the value of the schedule specified by name in this field.

##### 1.13.1.4 Field: Number of People Calculation Method

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal number of occupants (people) in the Zone. The key/choices are:

- People

With this choice, the method used will be a straight insertion of the number of occupants (people). (The Number of People field should be filled.)

- People/Area

With this choice, the method used will be a factor per floor area of the zone. (The People per Zone Floor Area field should be filled).

- Area/Person

With this choice, the method used will be a factor of floor area per person. (The Zone Floor Area per Person field should be filled).

##### 1.13.1.5 Field: Number of People

This field is used to represent the maximum number of people in a zone that is then multiplied by a schedule fraction (see schedule field). In EnergyPlus, this is slightly more flexible in that the number of people could be a "diversity factor" applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour, the number of people field is constant for all simulation environments.

##### 1.13.1.6 Field: People per Zone Floor Area

This factor (person/m<sup>2</sup>) is used, along with the Zone Floor Area to determine the maximum number of people as described in the Number of People field. The choice from the method field should be "people/area".

### 1.13.1.7 Field: Zone Floor Area per Person

This factor ( $m^2$ /person) is used, along with the Zone Floor Area to determine the maximum number of people as described in the Number of People field. The choice from the method field should be "area/person".

### 1.13.1.8 Field: Fraction Radiant

This field is a decimal number between 0.0 and 1.0 and is used to characterize the type of heat being given off by people in a zone. The number specified in this field will be multiplied by the total sensible energy emitted by people to give the amount of long wavelength radiation gain from human beings in a zone. The remainder of the sensible load is assumed to be convective heat gain. Note that latent gains from people are not included in either the radiant or convective heat gains. See the Engineering Reference document for more details.

### 1.13.1.9 Field: Sensible Heat Fraction

The user can use this field to specify a fixed sensible fraction for the heat gain due to this PEOPLE object. Normally the program calculates the sensible/latent split; this field gives the user control over this split. This field is autocalculated: if the field is blank or **autocalculate**, the program will calculate the sensible/latent split; if a value is entered, it will be used as the sensible fraction of the current total heat gain.

### 1.13.1.10 Field: Activity Level Schedule Name

This field is the name of the schedule that determines the amount of heat gain per person in the zone under design conditions. This value is modified somewhat based on a correlation to account for variations in space temperature. The schedule values may be any positive number and the units for this parameter is Watts per person. This schedule represents the total heat gain per person including convective, radiant, and latent. An internal algorithm is used to determine what fraction of the total is sensible and what fraction is latent. Then, the sensible portion is divided into radiant and convective portions using the value specified for Fraction Radiant (above). See the Engineering Reference document for more details.

Values for activity level can range anywhere from approximately 100-150 Watts per person for most office activities up to over 900 Watts per person for strenuous physical activities such as competitive wrestling. The following table (Table 11) is based on Table 4 from the 2005 ASHRAE Handbook of Fundamentals, page 8.6. In addition to the information from the ASHRAE HOF, there is an added column of values in W/Person such as necessary for the activity level schedule values. This column uses the standard adult body surface area of  $1.8 m^2$  to multiply the activity levels in  $W/m^2$  that are used in the table. Warnings are produced when the activity level schedule values fall outside normal ranges. Having too low or too high values can also skew thermal comfort reporting values.

### 1.13.1.11 Field: Carbon Dioxide Generation Rate

This numeric input field specifies carbon dioxide generation rate per person with units of  $m^3/s-W$ . The total carbon dioxide generation rate from this object is:

Number of People \* People Schedule \* People Activity \* Carbon Dioxide Generation Rate. The default value is  $3.82E-8 m^3/s-W$  (obtained from ASHRAE Standard 62.1-2007 value at 0.0084  $cfm/met/person$  over the general adult population). The maximum value can be 10 times the default value.

### 1.13.1.12 Field: Enable ASHRAE 55 comfort warnings

This field accepts either "Yes" or "No" as values. When "Yes" is specified, warnings are generated when the space conditions are outside of the ASHRAE 55 comfort range as discussed in the sections that follow titled "Simplified ASHRAE 55-2004 Graph Related Outputs" and "Simplified ASHRAE 55 Warnings." The default is not to provide these warnings so if you want to know if your space is outside this comfort range you must set this field to Yes.

Table 11. Metabolic Rates for Various Activities

Activity	Activity Level w/Person EnergyPlus Schedule Value	Activity Level W/m2	met*
Resting			
Sleeping	72	40	0.7
Reclining	81	45	0.8
Seated, quiet	108	60	1
Standing, relaxed	126	70	1.2
Walking (on level surface)			
3.2 km/h (0.9 m/s)	207	115	2
4.3 km/h (1.2 m/s)	270	150	2.6
6.4 km/h (1.8 m/s)	396	220	3.8
Office Activities			
Reading, seated	99	55	1
Writing	108	60	1
Typing	117	65	1.1
Filing, seated	126	70	1.2

Filing, standing	144	80	1.4
Walking about	180	100	1.7
Lifting/packing	216	120	2.1
Miscellaneous Occupational Activities			
Cooking	171 to 207	95 to 115	1.6 to 2.0
Housecleaning	207 to 360	115 to 200	2.0 to 3.4
Seated, heavy limb movement	234	130	2.2
Machine work	189	105	1.8
sawing (table saw)	207 to 252	115 to 140	2.0 to 2.4
light (electrical industry)	423	235	4
Handling 50 kg bags	423	235	4
Pick and shovel work	423 to 504	235 to 280	4.0 to 4.8
Miscellaneous Leisure Activities			
Dancing, social	252 to 459	140 to 255	2.4 to 4.4
Calisthenics/exercise	315 to 423	175 to 235	3.0 to 4.0
Tennis, singles	378 to 486	210 to 270	3.6 to 4.0
Basketball, competitive	522 to 792	290 to 440	5.0 to 7.6
Wrestling, competitive	738 to 909	410 to 505	7.0 to 8.7

\*Note that one met = 58.1 W/m<sup>2</sup>

#### 1.13.1.13 Field: Mean Radiant Temperature Calculation Type

This field specifies the type of Mean Radiant Temperature (MRT) calculation the user wishes to use for the thermal comfort model. At the present time, there are two options for MRT calculation type: zone averaged and surface weighted. The default calculation is "ZoneAveraged". In the zone averaged MRT calculation, the MRT used for the thermal comfort calculations is for an "average" point in the zone. MRT is calculated based on an area-emissivity weighted average of all of the surfaces in the zone. In cases where the emissivity of all of the surfaces are sufficiently small (near zero), the mean radiant temperature will be set to the mean air temperature of the space to avoid divide by zero errors. The other MRT calculation type is "SurfaceWeighted". The goal of this calculation type is to estimate a person in the space close to a particular surface without having to define exact view factors for all of the surfaces and the location of the person in the space. The MRT used in the thermal comfort calculations when the "surface weighted" calculation type is selected is actually the average of the temperature of the surface to which the person is closest (defined by the next field "Surface Name") and the zone averaged MRT (defined above). The surface temperature alone is not used because in theory the maximum view factor from a person to any flat surface is roughly 0.5. In the "surfaceweighted" calculation, the surface in question actually gets slightly more weighting than 50% since the surface selected is still a part of the zone average MRT calculation. Again, this simplification was made to avoid the specification of view factors and the exact location of the person.

A third option is to use "anglefactor". This option allows for more explicit positioning of the person within the space by defining the angle factors from the person to the various surfaces in the zone. This option requires the user to list the surfaces that the person can see from a radiation standpoint and also define the angle (or view) factor for each surface. The AngleFactorList object (see next object description) is intended to give the user this opportunity.

#### 1.13.1.14 Field: Surface Name/Angle Factor List Name

This field is only valid when the user selects "surfaceweighted" for the MRT calculation type (see the previous input field description). In this case, the field is the name of a surface within the zone the people are residing. This surface will be used in the MRT calculation as defined above to come up with a more representative MRT for a person near a particular surface. The MRT used for thermal comfort calculations using the "surface weighted" MRT calculation method is the average of the temperature of the surface specified in this field and the "zone averaged" MRT (see the Mean Radiant Temperature calculation type field above).

#### 1.13.1.15 Field: Work Efficiency Schedule Name

This field is the name of the schedule that determines the efficiency of energy usage within the human body that will be used for thermal comfort calculations. Note that all energy produced by the body is assumed to be converted to heat for the zone heat balance calculation. A value of zero corresponds to all of the energy produced in the body being converted to heat. A value of unity corresponds to all of the energy produced in the body being converted to mechanical

energy. The values for this parameter defined in the schedule must be between 0.0 and 1.0. Any value greater than zero will result in a reduction of heat that impacts the thermal comfort energy balance of a person within the space, resulting in PMV results appearing lower than expected. Ensure that if this value is non-zero, the base activity level is chosen to ensure that the net activity converted to heat and zone conditions are sufficient to maintain thermal comfort..

### 1.13.1.16 Field: Clothing Insulation Calculation Method

This field is a key/choice field that tells which of the next two fields are filled and is descriptive of the method for calculating the clothing insulation value of occupants (people) in the Zone. The key/choices are:

- ClothingInsulationSchedule

With this choice, the method used will be a straight insertion of the scheduled clothing insulation values of occupants (people). (The Clothing Insulation Schedule Name field should be filled.)

- DynamicClothingModelASHRAE55

With this choice, the method used will be the dynamic predictive clothing insulation model developed by Schiavon and Lee (2013) based on 6,333 selected observations taken from ASHRAE RP-884 and RP-921 databases. It varies the clothing insulation as a function of outdoor air temperature measured at 6am as illustrated below.

- CalculationMethodSchedule

With this choice, the method used can be either the ClothingInsulationSchedule or the DynamicClothingModelASHRAE55, depending on a schedule (to be entered as the next field) that determines which method to use in different time of a day. When this option is chosen, the next field "Clothing Insulation Calculation Method Schedule Name" is a required input.

Figure 48. Graphical representation for the dynamic predictive clothing insulation model

### 1.13.1.17 Field: Clothing Insulation Calculation Method Schedule Name

This field specifies which clothing insulation method (ClothingInsulationSchedule or DynamicClothingModelASHRAE55) to use at a particular time of the day. A schedule value of 1 means the ClothingInsulationSchedule method, and 2 means the DynamicClothingModelASHRAE55 method. This field is only required when the "Clothing Insulation Calculation Method" field is set to **CalculationMethodSchedule**. If this field is left blank, the specified clothing insulation calculation method will be used and not changed during the simulation.

### 1.13.1.18 Field: Clothing Insulation Schedule Name

This field is the name of the schedule that defines the amount of clothing being worn by a typical zone occupant during various times in the simulation period. The choice from the Clothing Insulation Calculation Method field should be "**ClothingInsulationSchedule**". This parameter must be a positive real number and has units of Clo. Typical values for Clo can be seen in the ASHRAE 2009 HOF Table 7, page 9.8 (for clothing ensembles) and Table 8, page 9.9 (for garment values) or [www.cbe.berkeley.edu/comfortool/](http://www.cbe.berkeley.edu/comfortool/).

### 1.13.1.19 Field: Air Velocity Schedule Name

This field is the name of the schedule that approximates the amount of air movement in the space as a function of time throughout the simulation period. The user has control over this parameter through the schedule that requires the individual numbers in the schedule to be positive real numbers having units of meters per second.

### 1.13.1.20 Field: Thermal Comfort Model Type (up to 5 allowed)

The final one to five fields are optional and are intended to trigger various thermal comfort models within EnergyPlus. By entering the keywords Fanger, Pierce, KSU, AdaptiveASH55, and AdaptiveCEN15251, the user can request the Fanger, Pierce Two-Node, Kansas State UniversityTwo-Node, and the adaptive comfort models of the ASHRAE Standard 55 and CEN Standard 15251 results for this particular people statement. Note that since up to five models may be specified, the user may opt to have EnergyPlus calculate the thermal comfort for people identified with this people statement using all five models if desired. Note that the KSU model is computationally intensive and may noticeably increase the execution time of the simulation. For descriptions of the thermal comfort calculations, see the Engineering Reference document.

The following IDF example allows for a maximum of 31 people with scheduled occupancy of "Office Occupancy", 60% radiant using an Activity Schedule of "Activity Sch". The example allows for thermal comfort reporting.

```
People,
  Kitchen_ZN_1_FLR_1,  !- Name
  Kitchen_ZN_1_FLR_1,  !- Zone or ZoneList Name
  BLDG_OCC_SCH,        !- Number of People Schedule Name
  People,              !- Number of People Calculation Method
  25.2000,,,          !- Number of People, People per Zone Floor Area, Zone Floor Area per Person
  0.3000,              !- Fraction Radiant
  AUTOCALCULATE,      !- Sensible Heat Fraction
  ACTIVITY_SCH,        !- Activity Level Schedule Name
  3.82E-8              !- Carbon Dioxide Generation Rate {m3/s-W}
  No,                  !- Enable ASHRAE 55 Comfort Warnings
  ZoneAveraged,        !- Mean Radiant Temperature Calculation Type
  ,                    !- Surface Name/Angle Factor List Name
  WORK_EFF_SCH,        !- Work Efficiency Schedule Name
  CLOTHING_SCH,        !- Clothing Insulation Schedule Name
  AIR_VELO_SCH,        !- Air Velocity Schedule Name
  Fanger;              !- Thermal Comfort Model 1 Type
```

A simpler example, without using the thermal comfort reporting option:

```
People,
  RIGHT FORK,          !- Name
  RIGHT FORK,          !- Zone or ZoneListName
  Dorm Occupancy,      !- Number of People Schedule Name
  people,              !- Number of People Calculation Method
  8.00000,             !- Number of People,
  ,                    !- People per Zone Floor Area
  ,                    !- Zone Floor Area per Person
  0.6000000,          !- Fraction Radiant
  Autocalculate,      !- Sensible Heat Fraction
  Activity Sch,        !- Activity level Schedule Name
```

And with the sensible fraction specified:

```
People,
  SPACE1-1 People 1,  !- Name
  SPACE1-1,           !- Zone or ZoneListName
  OCCUPY-1,           !- Number of People Schedule Name
  people,             !- Number of People Calculation Method
  11,                 !- Number of People
  ,                   !- People per Zone Floor Area
  ,                   !- Zone Floor Area per Person
  0.3,                !- Fraction Radiant
  0.55,               !- Sensible Heat Fraction
  ActSchd;            !- Activity level Schedule Name
```

Global People Object:

```
ZoneList,AllOccupiedZones,SPACE1-1,SPACE2-1,SPACE3-1,SPACE4-1,SPACE5-1;
```

```
People,
  AllZones with People,  !- Name
  AllOccupiedZones,      !- Zone or ZoneList Name
  OCCUPY-1,              !- Number of People Schedule Name
  People/Area,           !- Number of People Calculation Method
  ,                      !- Number of People
  .11,                   !- People per Zone Floor Area {person/m2}
  ,                      !- Zone Floor Area per Person {m2/person}
```

```

,             ! - Sensible Heat Fraction
ActSchd;      ! - Activity Level Schedule Name

```

### 1.13.2 People Outputs

People objects have output variables for individual objects and for zone totals.

People specific outputs include:

- Zone,Average,People Occupant Count []
- Zone,Sum,People Radiant Heating Energy [J]
- Zone,Average,People Radiant Heating Rate [W]
- Zone,Sum,People Convective Heating Energy [J]
- Zone,Average,People Convective Heating Rate [W]
- Zone,Sum,People Sensible Heating Energy [J]
- Zone,Average,People Sensible Heating Rate [W]
- Zone,Sum,People Latent Gain Energy [J]
- Zone,Average,People Latent Gain Rate [W]
- Zone,Sum,People Total Heating Energy [J]
- Zone,Average,People Total Heating Rate [W]
- Zone,Average,Zone People Occupant Count []
- Zone,Sum,Zone People Radiant Heating Energy [J]
- Zone,Average,Zone People Radiant Heating Rate [W]
- Zone,Sum,Zone People Convective Heating Energy [J]
- Zone,Average,Zone People Convective Heating Rate [W]
- Zone,Sum,Zone People Sensible Heating Energy [J]
- Zone,Average,Zone People Sensible Heating Rate [W]
- Zone,Sum,Zone People Latent Gain Energy [J]
- Zone,Average,Zone People Latent Gain Rate [W]
- Zone,Sum,Zone People Total Heating Energy [J]
- Zone,Average,People Air Temperature [C]
- Zone,Average,People Air Relative Humidity [%]
- Zone,Average,Zone People Total Heating Rate [W]
- Zone,Average,Zone Thermal Comfort Mean Radiant Temperature [C]
- Zone,Average,Zone Thermal Comfort Operative Temperature [C]
- Zone,Average,Zone Thermal Comfort Fanger Model PMV []
- Zone,Average,Zone Thermal Comfort Fanger Model PPD [%]
- Zone,Average,Zone Thermal Comfort Clothing Surface Temperature [C]
- Zone,Average,Zone Thermal Comfort Pierce Model Effective Temperature PMV []
- Zone,Average,Zone Thermal Comfort Pierce Model Standard Effective Temperature PMV []
- Zone,Average,Zone Thermal Comfort Pierce Model Discomfort Index []
- Zone,Average,Zone Thermal Comfort Pierce Model Thermal Sensation Index []

- Zone,Average,Zone Thermal Comfort KSU Model Thermal Sensation Index []
- Zone,Average,Zone Thermal Comfort ASHRAE 55 Adaptive Model 80% Acceptability Status []
- Zone,Average,Zone Thermal Comfort ASHRAE 55 Adaptive Model 90% Acceptability Status []
- Zone,Average,Zone Thermal Comfort ASHRAE 55 Adaptive Model Running Average Outdoor Air Temperature [C]
- Zone,Average,Zone Thermal Comfort ASHRAE 55 Adaptive Model Temperature [C]
- Zone,Average,Zone Thermal Comfort CEN 15251 Adaptive Model Category I Status []
- Zone,Average,Zone Thermal Comfort CEN 15251 Adaptive Model Category II Status []
- Zone,Average,Zone Thermal Comfort CEN 15251 Adaptive Model Category III Status
- Zone,Average,Zone Thermal Comfort CEN 15251 Adaptive Model Running Average Outdoor Air Temperature [C]
- Zone,Average,Zone Thermal Comfort CEN 15251 Adaptive Model Temperature [C]

#### 1.13.2.1 People Occupant Count []

This field is the number of people for this PEOPLE object during the timestep in question.

#### 1.13.2.2 People Radiant Heating Rate [W]

#### 1.13.2.3 People Radiant Heating Energy [J]

These output variables are the amount of radiant heat gain for this People object in Watts (for rate) or Joules. This is determined by the current sensible heat gain from people to the zone and the “Fraction Radiant” specified in the input. The radiant gains from people are distributed to the surfaces using an area weighting scheme.

#### 1.13.2.4 People Convective Heating Rate [W]

#### 1.13.2.5 People Convective Heating Energy [J]

These output variables are the amount of convective heat gain for this People object in Watts (for rate) or Joules. This is determined by the current sensible heat gain from people to the zone and the “Fraction Radiant” specified in input. Note that the radiant and convective gains should add up to the sensible heat gain from people. The convective heat gain from people is added to the zone air heat balance directly.

#### 1.13.2.6 People Latent Gain Rate [W]

#### 1.13.2.7 People Latent Gain Energy [J]

These output variables are the amount of latent heat gain for this People object in Watts (for rate) or Joules. This amount is based on the number of people in the space as well as the total amount of energy produced by a typical person defined by the activity schedule in the input. An internal algorithm is used to determine what fraction of the total is sensible and what fraction is latent. Details about this split are included in the Engineering Reference document.

#### 1.13.2.8 People Sensible Heating Rate [W]

#### 1.13.2.9 People Sensible Heating Energy [J]

These output variables are the amount of sensible heat gain for this People object in Watts (for rate) or Joules. This amount is based on the number of people in the space as well as the total amount of energy produced by a typical person defined by the activity schedule in the input. An internal algorithm (described in the Engineering Reference document) is used to determine what fraction of the total is sensible and what fraction is latent. The sensible plus the latent heat gain from people equals the total gain specified in the input.

#### 1.13.2.10 People Total Heating Rate [W]

#### 1.13.2.11 People Total Heating Energy [J]

These output variables are the total amount of heat gain for this People object in Watts (for rate) or Joules. This is derived from the activity level times the number of occupants.

#### 1.13.2.12 People Air Temperature [C]

This output variable represents the zone air temperature based on the Fanger thermal comfort model. If there is a ZoneControl:Thermostat:ThermalComfort object specified and the thermal zone is occupied, then the value of “People Air Temperature” is determined based on the thermal comfort that satisfies the thermal comfort setpoint PMV value specified; otherwise, it is set to average zone air temperature.

### 1.13.2.13 People Air Relative Humidity [%]

This output variable represents the zone air relative humidity based on the Fanger thermal comfort model. If there is a ZoneControl:Thermostat:ThermalComfort object specified and the thermal zone is occupied, then the value of "People Air Relative Humidity" is determined from the mean zone air temperature and zone air humidity ratio that satisfies the thermal comfort setpoint PMV value specified; otherwise, it is calculated from the zone air temperature and humidity ratio averaged over the time step.

### 1.13.2.14 Zone People Occupant Count []

This field is the total number of people within the zone during the timestep in question.

### 1.13.2.15 Zone People Radiant Heating Rate [W]

### 1.13.2.16 Zone People Radiant Heating Energy [J]

These output variables are the amount of radiant heat gain from people within the zone in Watts (for rate) or Joules. This is determined by the current sensible heat gain from people to the zone and the "Fraction Radiant" specified in the input. The radiant gains from people are distributed to the surfaces using an area weighting scheme.

### 1.13.2.17 Zone People Convective Heating Rate [W]

### 1.13.2.18 Zone People Convective Heating Energy [J]

These output variables are the amount of convective heat gain from people within the zone in Watts (for rate) or Joules. This is determined by the current sensible heat gain from people to the zone and the "Fraction Radiant" specified in input. Note that the radiant and convective gains should add up to the sensible heat gain from people. The convective heat gain from people is added to the zone air heat balance directly.

### 1.13.2.19 Zone People Latent Gain Rate [W]

### 1.13.2.20 Zone People Latent Gain Energy [J]

These output variables are the amount of latent heat gain from people within the zone in Watts (for rate) or Joules. This amount is based on the number of people in the space as well as the total amount of energy produced by a typical person defined by the activity schedule in the input. An internal algorithm is used to determine what fraction of the total is sensible and what fraction is latent. Details about this split are included in the Engineering Reference document.

### 1.13.2.21 Zone People Sensible Heating Rate [W]

### 1.13.2.22 Zone People Sensible Heating Energy [J]

These output variables are the amount of sensible heat gain from people within the zone in Watts (for rate) or Joules. This amount is based on the number of people in the space as well as the total amount of energy produced by a typical person defined by the activity schedule in the input. An internal algorithm (described in the Engineering Reference document) is used to determine what fraction of the total is sensible and what fraction is latent. The sensible plus the latent heat gain from people equals the total gain specified in the input.

### 1.13.2.23 Zone People Total Heating Rate [W]

### 1.13.2.24 Zone People Total Heating Energy [J]

These output variables are the total amount of heat gain from people within the zone in Watts (for rate) or Joules. Derived from the activity level times the number of occupants, this is summed for each people object within a zone.

### 1.13.2.25 Zone Thermal Comfort Mean Radiant Temperature [C]

This output variable is the mean radiant temperature used in the thermal comfort calculations. This value is computed according to the "MRT Calculation Type" specified in the PEOPLE object. If a high temperature radiant system is present in the zone, this value will be adjusted according to the current heater operation and the "Fraction of radiant energy incident on people" specified in the HIGH TEMP RADIANT SYSTEM object.

### 1.13.2.26 Zone Thermal Comfort Operative Temperature [C]

This output variable is the operative temperature as defined by the thermal comfort operations. Specifically, it is the average of the thermal comfort mean radiant temperature and the zone air temperature.

Note for all Thermal Comfort reporting: Though the published values for thermal comfort "vote" have a discrete scale (e.g. -3 to +3 or -4 to +4), the calculations in EnergyPlus are carried out on a continuous scale and, thus, reporting may be "off the scale" with specific conditions encountered in the space. This is not necessarily an error in EnergyPlus – rather a different approach that does not take the "limits" of the discrete scale values into account.

### 1.13.2.27 Zone Thermal Comfort Fanger Model PMV []

This field is the “predicted mean vote” (PMV) calculated using the Fanger thermal comfort model.

#### **1.13.2.28 Zone Thermal Comfort Fanger Model PPD [%]**

This field is the “predicted percentage of dissatisfied” (PPD) calculated using the Fanger thermal comfort model.

#### **1.13.2.29 Zone Thermal Comfort Clothing Surface Temperature [C]**

This output variable is the calculation of the clothing surface temperature using the Fanger thermal comfort model.

#### **1.13.2.30 Zone Thermal Comfort Pierce Model Effective Temperature PMV []**

This field is the “predicted mean vote” (PMV) calculated using the effective temperature and the Pierce two-node thermal comfort model.

#### **1.13.2.31 Zone Thermal Comfort Pierce Model Standard Effective Temperature PMV []**

This field is the “predicted mean vote” (PMV) calculated using the “standard” effective temperature and the Pierce two-node thermal comfort model.

#### **1.13.2.32 Zone Thermal Comfort Pierce Model Discomfort Index []**

This field is the “discomfort index” calculated using the the Pierce two-node thermal comfort model.

#### **1.13.2.33 Zone Thermal Comfort Pierce Model Thermal Sensation Index []**

This field is the “thermal sensation index” (PMV) calculated using the Pierce two-node thermal comfort model.

#### **1.13.2.34 Zone Thermal Comfort KSU Model Thermal Sensation Vote []**

This field is the “thermal sensation vote” (TSV) calculated using the KSU two-node thermal comfort model.

#### **1.13.2.35 Zone Thermal Comfort ASHRAE 55 Adaptive Model 90% Acceptability Status []**

This field is to report whether the operative temperature falls into the 90% acceptability limits of the adaptive comfort in ASHRAE 55-2010. A value of 1 means within (inclusive) the limits, a value of 0 means outside the limits, and a value of -1 means not applicable.

#### **1.13.2.36 Zone Thermal Comfort ASHRAE 55 Adaptive Model 80% Acceptability Status [ ]**

This field is to report whether the operative temperature falls into the 80% acceptability limits of the adaptive comfort in ASHRAE 55-2010. A value of 1 means within (inclusive) the limits, a value of 0 means outside the limits, and a value of -1 means not applicable.

#### **1.13.2.37 Zone Thermal Comfort ASHRAE 55 Adaptive Model Running Average Outdoor Air Temperature [C]**

This field reports the mean monthly outdoor air temperature, an input parameter for the ASHRAE-55 adaptive comfort model. This can be computed in two ways. If the .stat file is provided for the simulation, this field will reflect the monthly daily average temperature.

If the .epw file is used, the field reports the simple running average of the daily average outdoor dry-bulb temperatures of the previous 30 days.

#### **1.13.2.38 Zone Thermal Comfort ASHRAE 55 Adaptive Model Temperature [C]**

This field reports the ideal indoor operative temperature, or comfort temperature, as determined by the ASHRAE-55 adaptive comfort model. The 80% acceptability limits for indoor operative temperature are defined as no greater than 2.5 degrees C from the adaptive comfort temperature. The 90% acceptability limits are defined as no greater than 3.5 degrees C from the adaptive comfort temperature.

#### **1.13.2.39 Zone Thermal Comfort CEN 15251 Adaptive Model Category I Status**

This field is to report whether the operative temperature falls into the Category I (90% acceptability) limits of the adaptive comfort in the European Standard EN15251-2007. A value of 1 means within (inclusive) the limits, a value of 0 means outside the limits, and a value of -1 means not applicable.

#### **1.13.2.40 Zone Thermal Comfort CEN 15251 Adaptive Model Category II Status**

This field is to report whether the operative temperature falls into the Category II (80% acceptability) limits of the adaptive comfort in the European Standard EN15251-2007. A value of 1 means within (inclusive) the limits, a value of 0 means outside the limits, and a value of -1 means not applicable.

#### **1.13.2.41 Zone Thermal Comfort CEN 15251 Adaptive Model Category III Status**

This field is to report whether the operative temperature falls into the Category III (65% acceptability) limits of the adaptive comfort in the European Standard EN15251-2007. A value of 1 means within (inclusive) the limits, a value of 0 means outside the limits, and a value of -1 means not applicable.

### 1.13.2.42 Zone Thermal Comfort CEN 15251 Adaptive Model Running Average Outdoor Air Temperature

This field reports the weighted average of the outdoor air temperature of the previous five days, an input parameter for the CEN-15251 adaptive comfort model.

### 1.13.2.43 Zone Thermal Comfort CEN 15251 Adaptive Model Temperature

This field reports the ideal indoor operative temperature, or comfort temperature, as determined by the CEN-15251 adaptive comfort model. Category I, II, and III limits for indoor operative temperature are defined as no greater than 2, 3, and 4 degrees C from this value respectively.

### 1.13.3 Simplified ASHRAE 55-2004 Graph Related Outputs

The following output variables are all based on whether the humidity ratio and the operative temperature is within the region shown in ASHRAE Standard 55-2004 in Figure 5.2.1.1. For these outputs the operative temperature is simplified to be the average of the air temperature and the mean radiant temperature. For summer, the 0.5 Clo level is used and, for winter, the 1.0 Clo level is used. The graphs below are based on the following tables which extend the ASHRAE values to zero humidity ratio.

Table 12. Winter Clothes (1.0 Clo)

Operative Temperature (C)	Humidity Ratio (kgWater/kgDryAir)
19.6	0.012
23.9	0.012
26.3	0.000
21.7	0.000

Figure 49. Winter Comfort Range

Table 13. Summer Clothes (0.5 Clo)

Operative Temperature (C)	Humidity Ratio (kgWater/kgDryAir)
23.6	0.012
26.8	0.012
28.3	0.000
25.1	0.000

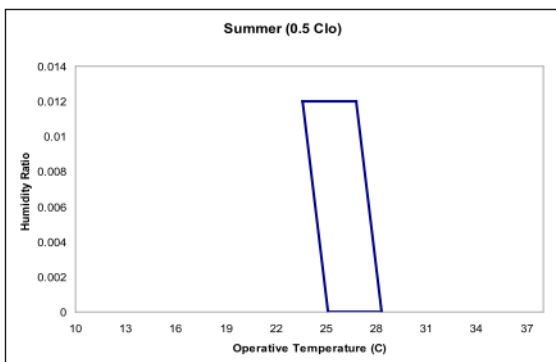

Figure 50. Summer Comfort Range

### 1.13.3.1 Zone Thermal Comfort ASHRAE 55 Simple Model Summer Clothes Not Comfortable Time[hr]

The time when the zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 summer clothes region (see above)

#### 1.13.3.2 Zone Thermal Comfort ASHRAE 55 Simple Model Winter Clothes Not Comfortable Time[hr]

The time when the zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 winter clothes region (see above)

#### 1.13.3.3 Zone Thermal Comfort ASHRAE 55 Simple Model Summer or Winter Clothes Not Comfortable Time[hr]

The time when the zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 summer or winter clothes region (see above)

#### 1.13.3.4 Facility Thermal Comfort ASHRAE 55 Simple Model Summer Clothes Not Comfortable Time[hr]

The time when any zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 summer clothes region (see above)

#### 1.13.3.5 Facility Thermal Comfort ASHRAE 55 Simple Model Winter Clothes Not Comfortable Time [hr]

The time when any zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 winter clothes region (see above)

#### 1.13.3.6 Facility Thermal Comfort ASHRAE 55 Simple Model Summer or Winter Clothes Not Comfortable Time [hr]

The time when any zone is occupied that the combination of humidity ratio and operative temperature is not in the ASHRAE 55-2004 summer or winter clothes region (see above)

### 1.13.4 Simplified ASHRAE 55 Warnings

The simplified ASHRAE 55 calculations may be computed for occupied zones and, possibly, warnings are shown on the .err file at the end of each simulated environment. To enable this option set the "Enable ASHRAE 55 comfort warnings" field of the People object to Yes. These warnings will not be generated by default.

If you enable the warnings, the simplified ASHRAE 55 calculations are done for occupied zones and, possibly, warnings are shown on the .err file at the end of each simulated environment.

```
** Warning ** More than 4% of time (350.4 hours) uncomfortable in zone ZSF1
**   ~~~   ** 553.0 hours were uncomfortable based on ASHRAE 55-2004 graph (Section 5.2.1.1)
**   ~~~   ** During Environment [10/01 - 09/30]: CHICAGO IL USA TMY2-94846 WMO\#=725300
** Warning ** More than 4% of time (350.4 hours) uncomfortable in zone ZNF1
**   ~~~   ** 827.8 hours were uncomfortable based on ASHRAE 55-2004 graph (Section 5.2.1.1)
**   ~~~   ** During Environment [10/01 - 09/30]: CHICAGO IL USA TMY2-94846 WMO\#=725300
** Warning ** More than 4% of time (350.4 hours) uncomfortable in zone ZSF2
**   ~~~   ** 593.5 hours were uncomfortable based on ASHRAE 55-2004 graph (Section 5.2.1.1)
**   ~~~   ** During Environment [10/01 - 09/30]: CHICAGO IL USA TMY2-94846 WMO\#=725300
** Warning ** More than 4% of time (350.4 hours) uncomfortable in zone ZNF2
**   ~~~   ** 875.8 hours were uncomfortable based on ASHRAE 55-2004 graph (Section 5.2.1.1)
**   ~~~   ** During Environment [10/01 - 09/30]: CHICAGO IL USA TMY2-94846 WMO\#=725300
```

You may decide if you need to change parameters to reduce these "uncomfortable" hours. The individual output variables shown previously may help you get more details on when these are occurring.

Following are some suggestions that might be applicable:

- Eliminate occupancy when conditioning equipment is off.
- Note that the ASHRAE graph lower limit is (19.6C to 21.7C) – heating setpoints may need to be nearer 22.2C (72F) than 21.1C (70F).
- Unoccupied heating setpoint should be nearer 16.7C (62F) rather than 12.8C (55F) to reduce the start up recovery.
- Start the occupied setpoint schedule, fan availability schedule, cooling pump availability schedule, reheat coil availability, one hour before occupancy. Seasonal turn on and off of equipment may cause more warnings (but potentially more energy consumption).
- Unoccupied cooling setpoint should be nearer 29.4C (85F) rather than 40.0 (104F) to reduce the start up recovery.

### 1.13.5 ComfortViewFactorAngles

When requesting EnergyPlus to do a thermal comfort calculation, the program user has three options for defining how the mean radiant temperature will be calculated. The user may select "zoneaveraged" which results in a mean radiant temperature that is characteristic of an "average" location near the center of the zone. The user may also elect to place the person near a particular surface by selecting "surfaceweighted" in the People statement. This takes the average of the

zone mean radiant temperature and the temperature of the surface that the person is near and uses this value as the mean radiant temperature when calculating thermal comfort.

The third option is for the user to more explicitly position the person within the space by defining the angle factors from the person to the various surfaces in the zone. This option requires the user to list the surfaces that the person can see from a radiation standpoint and also define the angle (or view) factor for each surface. The AngleFactorList input line is intended to give the user this opportunity.

#### 1.13.5.1 Field: Name

This field is an unique user assigned name for the list of surfaces that can be seen radiantly by the person for whom thermal comfort is to be evaluated. Any reference to this list by a People statement will use this name.

#### 1.13.5.2 Field: Zone Name

Zone Name for this surface list. Each of the surfaces listed must be in this zone.

#### 1.13.5.3 Field: Surface <#> Name

This field is the name of a surface in the zone seen by the person.

#### 1.13.5.4 Field: Angle Factor <#>

This field is the fraction that this surface contributes to the total mean radiant temperature. This can be thought of as a weighting factor for this surface and the actual mean radiant temperature used in the thermal comfort model is simply the sum of all angle factors multiplied by the corresponding inside surface temperature. Note that the Surface Name/Angle Factor pair can be repeated up to 20 times. The sum of all angle factors within any angle factor list must equal unity, otherwise the program will not accept the input as valid.

An example IDF with an electric low temperature radiant system is shown below.

```
ComfortViewFactorAngles,
  South Zone Angle Factors, !- name of angle factor list
  South Zone,              !- Zone Name
  Zn001:Flr001,           !- Surface name 1
  0.75,                   !- Angle factor for surface 1
  Zn001:Wall001,         !- Surface name 2
  0.15,                   !- Angle factor for surface 2
  Zn001:Roof001,         !- Surface name 3
  0.10;                   !- Angle factor for surface 3
```

### 1.13.6 Lights

The Lights statement allows you to specify information about a zone's electric lighting system, including design power level and operation schedule, and how the heat from lights is distributed thermally.

A zone may have multiple Lights statements. For example, one statement may describe the general lighting in the zone and another the task lighting. Or you can use multiple Lights statements for a zone that has two or more general lighting systems that differ in design level, schedule, etc.

#### 1.13.6.1 Field: Name

The name of the Lights object.

#### 1.13.6.2 Field: Zone or ZoneList Name

The field is the name of the thermal zone (ref: Zone) or ZoneList (ref: ZoneList) and links this Lights statement to a thermal zone or set of thermal zones in the building. When the ZoneList option is used then this lights definition is applied to each of the zones in the zone list effecting a global definition for the amount of light wattage in the zone. The Zonelist option can be used effectively with the watts/area and watts/person options of the Design Level Calculation Method.

The name of the actual lights object becomes <Zone Name> <Lights Object Name> and should be less than the standard length (100 characters) for a name field. If it is greater than this standard length, it may be difficult to specify in output reporting as it will be truncated. A warning will be shown if the generated name is greater than 100 characters. If it duplicates another such concatenated name, there will be a severe error and terminate the run.

#### 1.13.6.3 Field: Schedule Name

The name of the schedule that modifies the lighting power design level (see Design Level Calculation Method field and related subsequent fields). The schedule values can be any positive number. The electrical input for lighting in a particular timestep is the product of the design level and the value of this schedule in that timestep. If the design level is the maximum lighting power input the schedule should contain values between 0.0 and 1.0.

#### 1.13.6.4 Field: Design Level Calculation Method

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal lighting level in the

Zone. The key/choices are:

- LightingLevel

With this choice, the method used will be a straight insertion of the lighting level (Watts) for the Zone. (The Lighting Level field should be filled.)

- Watts/Area

With this choice, the method used will be a factor per floor area of the zone. (The Watts per Zone Floor Area field should be filled.)

- Watts/Person

With this choice, the method used will be a factor of lighting level (watts) per person. (The Watts per person field should be filled.)

#### 1.13.6.5 Field: Lighting Level

This is typically the maximum electrical power input (in Watts) to lighting in a zone, including ballasts, if present. This value is multiplied by a schedule fraction (see previous field) to get the lighting power in a particular timestep. In EnergyPlus, this is slightly more flexible in that the lighting design level could be a “diversity factor” applied to a schedule of real numbers.

#### 1.13.6.6 Field: Watts per Zone Floor Area

This factor (watts/m<sup>2</sup>) is used, along with the Zone Floor Area to determine the maximum lighting level as described in the Lighting Level field. The choice from the method field should be “watts/area”.

#### 1.13.6.7 Field: Watts per Person

This factor (watts/person) is used, along with the number of occupants (people) to determine the maximum lighting level as described in the Lighting Level field. The choice from the method field should be “watts/person”.

#### 1.13.6.8 Heat Gains from Lights:

The electrical input to lighting ultimately appears as heat that contributes to zone loads or to return air heat gains. In EnergyPlus this heat is divided into four different fractions. Three of these are given by the input fields Return Air Fraction, Fraction Radiant and Fraction Visible. A fourth, defined as the fraction of the heat from lights convected to the zone air, is calculated by the program as:

$$f_{\text{convected}} = 1.0 - (\text{Return Air Fraction} + \text{Fraction Radiant} + \text{Fraction Visible})$$

You will get an error message if Return Air Fraction + Fraction Radiant + Fraction Visible exceeds 1.0.

These fractions depend on the type of lamp and luminaire, whether the luminaire is vented to the return air, etc.

#### 1.13.6.9 Field: Return Air Fraction

The fraction of the heat from lights that goes into the zone return air (i.e., into the zone outlet node). If the return air flow is zero or the zone has no return air system, the program will put this fraction into the zone air. Return Air Fraction should be non-zero only for luminaires that are return-air ducted (see Table 14 and Figure 51). (However, see the field “Return Air Fraction Is Calculated from Plenum Temperature,” below, for an approach to modeling the case where Return Air Fraction is caused by *conduction* between a luminaire that is in contact with a return-air plenum.)

#### 1.13.6.10 Field: Fraction Radiant

The fraction of heat from lights that goes into the zone as long-wave (thermal) radiation. The program calculates how much of this radiation is absorbed by the inside surfaces of the zone according to the area times thermal absorptance product of these surfaces.

#### 1.13.6.11 Field: Fraction Visible

The fraction of heat from lights that goes into the zone as visible (short-wave) radiation. The program calculates how much of this radiation is absorbed by the inside surfaces of the zone according to the area times solar absorptance product of these surfaces.

Approximate values of Return Air Fraction, Fraction Radiant and Fraction Visible are given in Table 14 for overhead fluorescent lighting for the luminaire configurations shown in Figure 51.

Table 14. Approximate values of Return Air Fraction, Fraction Radiant and Fraction Visible for overhead fluorescent lighting for different luminaire configurations. These values assume that no light heat goes into an adjacent zone. Source: *Lighting Handbook: Reference & Application*, 8<sup>th</sup> Edition, Illuminating Engineering Society of North America, New York, 1993, p. 355.

#### Luminaire Configuration, Fluorescent Lighting

Field Name	Suspended	Surface Mount	Recessed	Luminous and louvered ceiling	Return-air ducted
------------	-----------	---------------	----------	-------------------------------	-------------------

Return Air Fraction	0.0	0.0	0.0	0.54
Fraction Radiant	0.42	0.72	0.37	0.37
Fraction Visible	0.18	0.18	0.18	0.18
$f_{\text{convected}}$	0.40	0.10	0.45	0.45

Figure 51. Overhead fluorescent luminaire configurations.

**1.13.6.12 Field: Fraction Replaceable**

This field defines the daylighting control for the LIGHTS object.

If **Daylighting:Controls** or **Daylighting:DELight:Controls** is specified for the zone, this field is used as an on/off flag for dimming controls. If set to 0.0, the lights are not dimmed by the daylighting controls. If set to 1.0, the lights are allowed to be dimmed by the daylighting controls.

**1.13.6.13 Field: End-Use Subcategory**

Allows you to specify a user-defined end-use subcategory, e.g., "Task Lights", "Hall Lights", etc. A new meter for reporting is created for each unique subcategory (ref: Output:Meter objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the lights will be assigned to the "General" end-use subcategory.

**1.13.6.14 Field: Return Air Fraction Calculated from Plenum Temperature**

Accepts values Yes or No (the default). Yes is for advanced used only. In this case the program will calculate the return air fraction by assuming that it is due to conduction of some of the light heat into the zone's return air plenum and that the amount of the conduction depends on the plenum air temperature. A Yes value should only be used for luminaires that are recessed and non-vented, as shown in Figure 52.

The value you enter for the Return Air Fraction field will be ignored and you can enter, for fluorescent lighting, Fraction Radiant = 0.37 and Fraction Visible = 0.18, as indicated in Table 14.

This feature requires that the coefficients described below be determined from measurements or detailed calculations since they are very sensitive to the luminaire type, lamp type, thermal resistance between fixture and plenum, etc.

If "Return Air Fraction Is Calculated from Plenum Temperature" = Yes, the return air fraction is calculated *each timestep* from the following empirical correlation:

$$(\text{Return Air Fraction})_{\text{calculated}} = C_1 - C_2 \times T_{\text{plenum}}$$

where  $T_{\text{plenum}}$  is the previous-time-step value of the return plenum air temperature (C),

and  $C_1$  and  $C_2$  are the values of the coefficients entered in the next two fields.

To compensate for the change in the return air fraction relative to its input value, the program modifies Fraction Radiant and  $f_{\text{convected}}$  by a scale factor such that

$$(\text{Return Air Fraction})_{\text{calculated}} + (\text{Fraction Radiant})_{\text{modified}} + (f_{\text{convected}})_{\text{modified}} + (\text{Fraction Visible})_{\text{input}} = 1.0$$

It is assumed that Fraction Visible is a constant equal to its input value.

**1.13.6.15 Field: Return Air Fraction Function of Plenum Temperature Coefficient 1**

The coefficient  $C_1$  in the equation for  $(\text{Return Air Fraction})_{\text{calculated}}$ .

**1.13.6.16 Field: Return Air Fraction Function of Plenum Temperature Coefficient 2**

The coefficient  $C_2$  in the equation for  $(\text{Return Air Fraction})_{\text{calculated}}$ . Its units are  $1/^\circ\text{C}$ .

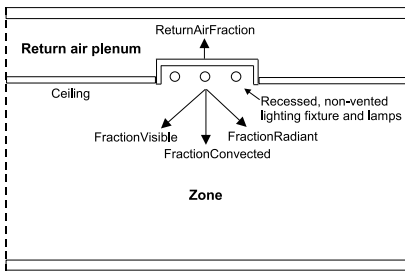

Figure 52. Vertical section through a zone and its return air plenum showing recessed lighting (not to scale). The heat from lights is divided into four fractions, three of which—ReturnAirFraction, FractionRadiant and FractionConvected—depend on plenum air temperature.

### 1.13.7 Lights Report Outputs

If daylighting controls are operating in the zone, all of the Lights objects with a Fraction Replaceable greater than zero will be reduced by a multiplicative factor that accounts for how much the electric lighting is lowered due to daylighting.

Lights objects have output variables for individual objects and for zone totals.

- Zone,Average,Lights Electric Power [W]
- Zone,Sum,Lights Radiant Heat Gain [J]
- Zone,Average,Lights Radiant Heating Rate [W]

- Zone,Average,Zone Lights Return Air Heating Rate [W]
- Zone,Sum,Zone Lights Total Heating Energy [J]
- Zone,Average,Zone Lights Total Heating Rate [W]
- Zone,Sum,Zone Lights Electric Energy [J]

#### **1.13.7.1 Lights Electric Power [W]**

The electric power input for the lights.

#### **1.13.7.2 Lights Radiant Heating Rate [W]**

#### **1.13.7.3 Lights Radiant Heating Energy [J]**

The amount of heat gain from lights that is in the form of long-wave (thermal) radiation entering the zone. This heat is absorbed by the inside surfaces of the zone according to an area times long-wave absorptance weighting scheme.

#### **1.13.7.4 Lights Visible Radiation Heating Rate [W]**

#### **1.13.7.5 Lights Visible Radiation Heating Energy [J]**

The amount of heat gain from lights that is in the form of visible (short-wave) radiation entering the zone. This heat is absorbed by the inside surfaces of the zone according to an area times short-wave absorptance weighting scheme.

#### **1.13.7.6 Lights Convective Heating Rate [W]**

#### **1.13.7.7 Lights Convective Heating Energy [J]**

The amount of heat gain from lights that is convected to the zone air.

#### **1.13.7.8 Lights Return Air Heating Rate [W]**

#### **1.13.7.9 Lights Return Air Heating Energy [J]**

The amount of heat gain from lights that goes into the zone's return air (and, therefore, does not directly contribute to the zone load). If the zone has no return air system or the zone's air system is off, this heat will be added to the zone air.

#### **1.13.7.10 Lights Total Heating Rate [W]**

#### **1.13.7.11 Lights Total Heating Energy [J]**

The total heat gain from lights. It is the sum of the following four outputs, i.e., Total Heat Gain = Return Air Heat Gain + Radiant Heat Gain + Visible Heat Gain + Convective Heat Gain. It is also equal to the electrical input to the lights.

#### **1.13.7.12 Lights Electric Energy [J]**

The lighting electrical consumption including ballasts, if present. These will have the same value as Lights Total Heating Energy (above).

#### **1.13.7.13 Zone Lights Electric Power [W]**

The electric power input for all lights in the zone.

#### 1.13.7.14 Zone Lights Radiant Heating Rate [W]

#### 1.13.7.15 Zone Lights Radiant Heating Energy [J]

The amount of heat gain from all lights in the zone that is in the form of long-wave (thermal) radiation entering the zone. This heat is absorbed by the inside surfaces of the zone according to an area times long-wave absorptance weighting scheme.

#### 1.13.7.16 Zone Lights Visible Radiation Heating Rate [W]

#### 1.13.7.17 Zone Lights Visible Radiation Heating Energy [J]

The amount of heat gain from all lights in the zone that is in the form of visible (short-wave) radiation entering the zone. This heat is absorbed by the inside surfaces of the zone according to an area times short-wave absorptance weighting scheme.

#### 1.13.7.18 Zone Lights Convective Heating Rate [W]

#### 1.13.7.19 Zone Lights Convective Heating Energy [J]

The amount of heat gain from all lights in the zone that is convected to the zone air.

#### 1.13.7.20 Zone Lights Return Air Heating Rate [W]

#### 1.13.7.21 Zone Lights Return Air Heating Energy [J]

The amount of heat gain from all lights in the zone that goes into the zone's return air (and, therefore, does not directly contribute to the zone load). If the zone has no return air system or the zone's air system is off, this heat will be added to the zone air.

#### 1.13.7.22 Zone Lights Total Heating Rate [W]

#### 1.13.7.23 Zone Lights Total Heating Energy [J]

The total heat gain from all lights in the zone. It is the sum of the following four outputs, i.e., Total Heat Gain = Return Air Heat Gain + Radiant Heat Gain + Visible Heat Gain + Convective Heat Gain. It is also equal to the electrical input to the lights.

#### 1.13.7.24 Zone Lights Electric Energy [J]

The lighting electrical consumption for all lights in the zone including ballasts, if present. This will have the same value as Zone Lights Total Heating Energy (above). However, this amount is also shown in the Electricity meters that are associated with the zone:

Electricity:Facility,

Electricity:Building,

Electricity:Zone:<Zone Name>.

In addition, depending on use, it will be shown in:

InteriorLights: Electricity and

InteriorLights:Electricity:Zone :<Zone Name>.

### 1.13.8 Meters for Lights Outputs

As described in the Lights Outputs, values for lights will show up on the following meters:

Table 15. Distribution of Lights to Meters

Meter Name	Scope	Lights Specifics
Electricity:Facility	Entire Facility	All
Electricity:Building	All Zones	All
Electricity:Zone:<Zone Name>	Specific Zone	All
InteriorLights:Electricity	All Zones	Lights Use
InteriorLights:Electricity:Zone:<Zone Name>	Specific Zone	Lights Use
<End-Use Subcategory>:InteriorLights:Electricity Specific Subcategory		Lights Use

### 1.13.9 ElectricEquipment

The object models equipment in the zone which consumes electricity, such as computers, televisions, and cooking equipment, also known as "plug loads." All of

the energy consumed by the equipment becomes a heat gain in the zone or is lost (exhausted) as specified below.

#### 1.13.9.1 Field: Name

The name of the ElectricEquipment object.

#### 1.13.9.2 Field: Zone or ZoneList Name

This field is the name of the zone (ref: Zone) or ZoneList (ref: ZoneList) and attaches a particular electric equipment statement to a thermal zone or set of thermal zones in the building. When the ZoneList option is used then this electric equipment definition is applied to each of the zones in the zone list effecting a global definition for the amount of electric wattage in the zone. The ZoneList option can be used effectively with the watts/area and watts/person options of the Design Level Calculation Method.

The name of the actual electric equipment object becomes <Zone Name> <ElectricEquipment Object Name> and should be less than the standard length (100 characters) for a name field. If it is greater than this standard length, it may be difficult to specify in output reporting as it will be truncated. A warning will be shown if the generated name is greater than 100 characters. If it duplicates another such concatenated name, there will be a severe error and terminate the run.

#### 1.13.9.3 Field: Schedule Name

This field is the name of the schedule that modifies the design level parameter for electric equipment (see Design Level Calculation Method field and related subsequent fields). The schedule values can be any positive number. The actual electrical input for equipment in a zone as defined by this statement is the product of the design level field and the value of the schedule specified by name in this field.

#### 1.13.9.4 Field: Design Level Calculation Method

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal electric equipment level in the Zone. The key/choices are:

- EquipmentLevel

With this choice, the method used will be a straight insertion of the electric equipment level (Watts) for the Zone. (The Design Level field should be filled.)

- Watts/Area

With this choice, the method used will be a factor per floor area of the zone. (The Watts per Zone Floor Area field should be filled.)

- Watts/Person

With this choice, the method used will be a factor of equipment level (watts) per person. (The Watts per Person field should be filled.)

#### 1.13.9.5 Field: Design Level

This field (in Watts) is typically used to represent the maximum electrical input to equipment in a zone that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the electric equipment design level could be a "diversity factor" applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour, the design level field is constant for all simulation environments.

#### 1.13.9.6 Field: Watts per Zone Floor Area

This factor (watts/m<sup>2</sup>) is used, along with the Zone Area to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be "Watts/Area".

#### 1.13.9.7 Field: Watts per Person

This factor (watts/person) is used, along with the number of occupants (people) to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be "Watts/Person".

#### 1.13.9.8 Heat Gains from Electric Equipment:

The electrical input to the equipment ultimately appears as heat that contributes to zone loads. In EnergyPlus this heat is divided into four different fractions. Three of these are given by the input fields Fraction Latent, Fraction Radiant and Fraction Lost. A fourth, defined as the fraction of the heat from electric equipment convected to the zone air, is calculated by the program as:

$$f_{\text{convected}} = 1.0 - (\text{Fraction Latent} + \text{Fraction Radiant} + \text{Fraction Lost})$$

You will get an error message if Fraction Latent + Fraction Radiant + Fraction Lost exceeds 1.0.

#### 1.13.9.9 Field: Fraction Latent

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of latent heat given off by electric equipment in a zone. The number

specified in this field will be multiplied by the total energy consumed by electric equipment to give the amount of latent energy produced by the electric equipment. This energy affects the moisture balance within the zone.

#### 1.13.9.10 Field: Fraction Radiant

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of long-wave radiant heat being given off by electric equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by electric equipment to give the amount of long wavelength radiation gain from electric equipment in a zone.

#### 1.13.9.11 Field: Fraction Lost

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of "lost" heat being given off by electric equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by electric equipment to give the amount of heat which is "lost" and does not impact the zone energy balances. This might correspond to electrical energy converted to mechanical work or heat that is vented to the atmosphere.

#### 1.13.9.12 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Computers", "Copy Machines", etc. A new meter for reporting is created for each unique subcategory (ref: Output:Meter objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the equipment will be assigned to the "General" end-use subcategory.

An IDF example:

```
ElectricEquipment,
  DORM ROOMS AND COMMON AREAS ElecEq 1,  !- Name
  DORM ROOMS AND COMMON AREAS,  !- Zone Name
  Residence Equipment,  !- SCHEDULE Name
  EquipmentLevel,  !- Design Level calculation method
  9210.921,  !- Design Level {W}
  ,  !- Watts per Zone Floor Area {watts/m2}
  ,  !- Watts per Person {watts/person}
  0.0000000E+00,  !- Fraction Latent
  0.3000000,  !- Fraction Radiant
  0.0000000E+00,  !- Fraction Lost
  Computers;  !- End-use Subcategory
```

Global ElectricEquipment example:

```
ZoneList,AllOccupiedZones,SPACE1-1,SPACE2-1,SPACE3-1,SPACE4-1,SPACE5-1;
```

```
ElectricEquipment,
  AllZones with Electric Equipment,  !- Name
  AllOccupiedZones,  !- Zone or ZoneList Name
  EQUIP-1,  !- Schedule Name
  Watts/Person,  !- Design Level Calculation Method
  ,  !- Design Level {W}
  ,  !- Watts per Zone Floor Area {W/m2}
  96,  !- Watts per Person {W/person}
  0,  !- Fraction Latent
  0.3,  !- Fraction Radiant
  0;  !- Fraction Lost
```

### 1.13.10 GasEquipment

The object models equipment in the zone which consumes natural gas, such as cooking equipment or a gas fireplace. All of the energy consumed by the equipment becomes a heat gain in the zone or is lost (exhausted) as specified below.

#### 1.13.10.1 Field: Name

The name of the GasEquipment object.

#### 1.13.10.2 Field: Zone or ZoneList Name

This field is the name of the thermal zone (ref: Zone) or ZoneList (ref: ZoneList) and attaches a particular gas equipment statement to a thermal zone or set of thermal zones in the building. When the ZoneList option is used then this gas equipment definition is applied to each of the zones in the zone list effecting a global definition for the amount of gas in the zone. The Zonelist option can be used effectively with the watts/area and watts/person options of the Design Level Calculation Method.

The name of the actual gas equipment object becomes <Zone Name> <GasEquipment Object Name> and should be less than the standard length (100 characters) for a name field. If it is greater than this standard length, it may be difficult to specify in output reporting as it will be truncated. A warning will be shown if the generated name is greater than 100 characters. If it duplicates another such concatenated name, there will be a severe error and terminate the run.

#### 1.13.10.3 Field: Schedule Name

This field is the name of the schedule that modifies the design level parameter for gas equipment (see Design Level Calculation Method field and related subsequent fields). The schedule values can be any positive number. The actual energy input for gas equipment in a zone as defined by this statement is the product of the design level field and the value of the schedule specified by name in this field.

#### 1.13.10.4 Field: Design Level Calculation Method

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal gas equipment level in the Zone. The key/choices are:

- EquipmentLevel

With this choice, the method used will be a straight insertion of the gas equipment level (Watts) for the Zone. (The Design Level field should be filled.)

- Watts/Area or Power/Area

With this choice, the method used will be a factor per floor area of the zone. (The Power per Zone Floor Area field should be filled).

- Watts/Person or Power/Person

With this choice, the method used will be a factor of equipment level (watts) per person. (The Power per Person field should be filled).

#### 1.13.10.5 Field: Design Level

This field (in Watts) is typically used to represent the maximum energy input to gas equipment in a zone that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the gas equipment design level could be a "diversity factor" applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour, the design level field is constant for all simulation environments.

#### 1.13.10.6 Field: Power per Zone Floor Area

This factor (watts/m<sup>2</sup>) is used, along with the Zone Area to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be "Watts/Area" or "Power/Area".

#### 1.13.10.7 Field: Power per Person

This factor (watts/person) is used, along with the number of occupants (people) to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be "Watts/Person" or "Power/Person".

#### 1.13.10.8 Heat Gains from Gas Equipment:

The fuel input to the equipment ultimately appears as heat that contributes to zone loads. In EnergyPlus this heat is divided into four different fractions. Three of these are given by the input fields Fraction Latent, Fraction Radiant and Fraction Lost. A fourth, defined as the fraction of the heat from gas equipment convected to the zone air, is calculated by the program as:

$$f_{\text{convected}} = 1.0 - (\text{Fraction Latent} + \text{Fraction Radiant} + \text{Fraction Lost})$$

You will get an error message if Fraction Latent + Fraction Radiant + Fraction Lost exceeds 1.0.

#### 1.13.10.9 Field: Fraction Latent

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of latent heat given off by gas equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by gas equipment to give the amount of latent energy produced by the gas equipment. This energy affects the moisture balance within the zone.

#### 1.13.10.10 Field: Fraction Radiant

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of long-wave radiant heat being given off by gas equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by gas equipment to give the amount of long wavelength radiation gain from gas equipment in a zone.

#### 1.13.10.11 Field: Fraction Lost

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of "lost" heat being given off by gas equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by gas equipment to give the amount of heat which is "lost" and does not impact the zone energy balances. This might correspond to input energy converted to mechanical work or heat that is vented to the atmosphere.

#### 1.13.10.12 Field: Carbon Dioxide Generation Rate

This numeric input field specifies carbon dioxide generation rate with units of m3/s-W. The default value of 0.0 assumes the equipment is fully vented to outdoors. In the absence of better information, the user might consider using a value of 3.45E-8 m3/s-W which assumes the equipment is not vented to outdoors. This value is converted from natural gas CO<sub>2</sub> emission rate at 11.7 lbs CO<sub>2</sub> per therm. The CO<sub>2</sub> emission rate is provided by U.S. Energy Information Administration, "Frequently Asked Questions - Environment, Questions About Environmental Emissions", [http://tonto.eia.doe.gov/ask/environment\\_faqs.asp#CO2\\_quantity](http://tonto.eia.doe.gov/ask/environment_faqs.asp#CO2_quantity), January 2010. The maximum value for this input field is 3.45E-7 m3/s-W.

### 1.13.10.13 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Cooking", "Clothes Drying", etc. A new meter for reporting is created for each unique subcategory (ref: Output:Meter objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the equipment will be assigned to the "General" end-use subcategory.

An IDF example:

```
GasEquipment,
  DORM ROOMS AND COMMON AREAS GasEq 1,  !- Name
  DORM ROOMS AND COMMON AREAS,  !- Zone Name
  Gas Eq Sch,  !- Schedule Name

### 1.13.11 HotWaterEquipment

The object models hot water equipment in the zone which consumes district heating, such as cooking equipment or process loads. All of the energy consumed by the equipment becomes a heat gain in the zone or is lost (exhausted) as specified below. This object consumes district heating energy directly and does not cause a load on a hot water plant loop or water heater. For domestic hot water uses, such as sinks and showers, see WaterUse:Equipment.

#### 1.13.11.1 Field: Name

The name of the HotWaterEquipment object.

#### 1.13.11.2 Field: Zone or ZoneList Name

This field is the name of the thermal zone (ref: Zone) or ZoneList (ref: ZoneList) and attaches a particular hot water equipment statement to a thermal zone or set of thermal zones in the building. When the ZoneList option is used then this hot water equipment definition is applied to each of the zones in the zone list effecting a global definition for the amount of hot water in the zone. The Zonelist option can be used effectively with the watts/area and watts/person options of the Design Level Calculation Method.

The name of the actual hot water equipment object becomes <Zone Name> <HotWaterEquipment Object Name> and should be less than the standard length (100 characters) for a name field. If it is greater than this standard length, it may be difficult to specify in output reporting as it will be truncated. A warning will be shown if the generated name is greater than 100 characters. If it duplicates another such concatenated name, there will be a severe error and terminate the run.

#### 1.13.11.3 Field: Schedule Name

This field is the name of the schedule that modifies the design level parameter for hot water equipment (see Design Level Calculation Method field and related subsequent fields). The schedule values can be any positive number. The actual energy input for hot water equipment in a zone as defined by this statement is the product of the design level field and the value of the schedule specified by name in this field.

#### 1.13.11.4 Field: Design Level Calculation Method

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal hot water equipment level in the Zone. The key/choices are:

- EquipmentLevel

With this choice, the method used will be a straight insertion of the hot water equipment level (Watts) for the Zone. (The Design Level field should be filled.)

- Watts/Area or Power/Area

With this choice, the method used will be a factor per floor area of the zone. (The Power per Zone Floor Area field should be filled).

- Watts/Person or Power/Person

With this choice, the method used will be a factor of equipment level (watts) per person. (The Power per Person field should be filled).

#### 1.13.11.5 Field: Design Level

This field (in Watts) is typically used to represent the maximum energy input to hot water equipment in a zone that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the hot water equipment design level could be a "diversity factor" applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour, the design level field is constant for all simulation environments.

#### 1.13.11.6 Field: Power per Zone Floor Area

This factor (watts/m<sup>2</sup>) is used, along with the Zone Area to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be "Watts/Area" or "Power/Area".

#### 1.13.11.7 Field: Power per Person

This factor (watts/person) is used, along with the number of occupants (people) to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be "Watts/Person" or "Power/Person".

#### 1.13.11.8 Heat Gains from Hot Water Equipment:

The fuel input to the equipment ultimately appears as heat that contributes to zone loads. In EnergyPlus this heat is divided into four different fractions. Three of these are given by the input fields Fraction Latent, Fraction Radiant and Fraction Lost. A fourth, defined as the fraction of the heat from hot water equipment convected to the zone air, is calculated by the program as:

$$f_{\text{convected}} = 1.0 - (\text{Fraction Latent} + \text{Fraction Radiant} + \text{Fraction Lost})$$

You will get an error message if Fraction Latent + Fraction Radiant + Fraction Lost exceeds 1.0.

#### 1.13.11.9 Field: Fraction Latent

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of latent heat given off by hot water equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by hot water equipment to give the amount of latent energy produced by the hot water equipment. This energy affects the moisture balance within the zone.

#### 1.13.11.10 Field: Fraction Radiant

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of long-wave radiant heat being given off by hot water equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by hot water equipment to give the amount of long wavelength radiation gain from hot water equipment in a zone.

#### 1.13.11.11 Field: Fraction Lost

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of "lost" heat being given off by hot water equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by hot water equipment to give the amount of heat which is "lost" and does not impact the zone energy balances. This might correspond to input energy converted to mechanical work or heat that is vented to the atmosphere.

#### 1.13.11.12 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Cooking", "Clothes Drying", etc. A new meter for reporting is created for each unique subcategory (ref: Output:Meter object). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the equipment will be assigned to the "General" end-use subcategory.

IDF Examples:

  ,                                           !- Power per Person {W/Person}
  0.0000000E+00,                             !- Fraction Latent
  0.3000000,                                 !- Fraction Radiant
  0.0000000E+00;                             !- Fraction Lost

```

### 1.13.12 SteamEquipment

The object models steam equipment in the zone which consumes district heating, such as cooking equipment or process loads. All of the energy consumed by the equipment becomes a heat gain in the zone or is lost (exhausted) as specified below. This object consumes district heating energy directly and does not cause a load on a steam plant loop.

#### 1.13.12.1 Field: Name

The name of the SteamEquipment object.

#### 1.13.12.2 Field: Zone or ZoneList Name

This field is the name of the thermal zone (ref: Zone) and attaches a particular steam equipment statement to a thermal zone or set of thermal zones in the building. When the ZoneList option is used then this steam equipment definition is applied to each of the zones in the zone list effecting a global definition for the amount of steam in the zone. This option can be used effectively with the watts/area and watts/person options of the Design Level Calculation Method.

#### 1.13.12.3 Field: Schedule Name

This field is the name of the schedule that modifies the design level parameter for steam equipment (see Design Level Calculation Method field and related subsequent fields). The schedule values can be any positive number. The actual energy input for steam equipment in a zone as defined by this statement is the product of the design level field and the value of the schedule specified by name in this field.

#### 1.13.12.4 Field: Design Level Calculation Method

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal steam equipment level in the Zone. The key/choices are:

- EquipmentLevel

With this choice, the method used will be a straight insertion of the steam equipment level (Watts) for the Zone. (The Design Level field should be filled.)

- Watts/Area or Power/Area

With this choice, the method used will be a factor per floor area of the zone. (The Power per Zone Floor Area field should be filled).

- Watts/Person or Power/Person

With this choice, the method used will be a factor of equipment level (watts) per person. (The Power per Person field should be filled).

#### 1.13.12.5 Field: Design Level

This field (in Watts) is typically used to represent the maximum energy input to steam equipment in a zone that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the steam equipment design level could be a "diversity factor" applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour, the design level field is constant for all simulation environments.

#### 1.13.12.6 Field: Power per Zone Floor Area

This factor (watts/m<sup>2</sup>) is used, along with the Zone Area to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be "Watts/Area" or "Power/Area".

#### 1.13.12.7 Field: Power per Person

This factor (watts/person) is used, along with the number of occupants (people) to determine the maximum equipment level as described in the Design Level field. The choice from the method field should be "Watts/Person" or "Power/Person".

#### 1.13.12.8 Heat Gains from Steam Equipment:

The fuel input to the equipment ultimately appears as heat that contributes to zone loads. In EnergyPlus this heat is divided into four different fractions. Three of these are given by the input fields Fraction Latent, Fraction Radiant and Fraction Lost. A fourth, defined as the fraction of the heat from steam equipment convected to the zone air, is calculated by the program as:

$$f_{\text{convected}} = 1.0 - (\text{Fraction Latent} + \text{Fraction Radiant} + \text{Fraction Lost})$$

You will get an error message if Fraction Latent + Fraction Radiant + Fraction Lost exceeds 1.0.

#### 1.13.12.9 Field: Fraction Latent

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of latent heat given off by steam equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by steam equipment to give the amount of latent energy produced by the steam equipment. This energy affects the moisture balance within the zone.

#### 1.13.12.10 Field: Fraction Radiant

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of long-wave radiant heat being given off by steam equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by steam equipment to give the amount of long wavelength radiation gain from steam equipment in a zone.

#### 1.13.12.11 Field: Fraction Lost

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of "lost" heat being given off by steam equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by steam equipment to give the amount of heat which is "lost" and does not impact the zone energy balances. This might correspond to input energy converted to mechanical work or heat that is vented to the atmosphere.

#### 1.13.12.12 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Cooking", "Clothes Drying", etc. A new meter for reporting is created for each unique subcategory (ref: Output:Meter objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the equipment will be assigned to the "General" end-use subcategory.

IDF Examples:

```
SteamEquipment,
  SPACE4-1 ElecEq 1,      !- Name
  SPACE4-1,              !- Zone Name
  EQUIP-1,               !- SCHEDULE Name

  1050,                  !- Design Level {W}
  ,                      !- Power per Zone Floor Area {watts/m2}
  ,                      !- Power per Person {watts/person}
  0.5,                  !- Fraction Latent
  0.3,                  !- Fraction Radiant
  0,                    !- Fraction Lost
  Laundry;              !- End-Use Subcategory
```

#### 1.13.13 SwimmingPool:Indoor

The Indoor Swimming Pool object is used to describe the indoor swimming pools that are exposed to the internal environment. There are several rules that should be noted regarding the specification of an indoor pool in EnergyPlus. First, the pool is linked to a surface that must be a floor. The pool is assumed to cover the entire floor to which it is linked. If the pool only covers part of the floor in the actual building, then the user must break the floor up into multiple sections.

As pools attempt to achieve a particular water temperature and have a variety of heat losses, heating equipment is necessary to maintain the proper setpoint temperature. In EnergyPlus, the pool itself becomes part of the demand side of a plant loop with heating equipment on the supply side providing whatever heating is needed to maintain the desired temperature. This heating equipment as well as the loop connections must be entered separately and the input shown in this section only details what is needed to specify the pool itself.

The following information is useful for defining and modeling an indoor pool in EnergyPlus. For more information on the algorithm used for this model or details on

some of the input parameters, please reference the indoor pool section of the EnergyPlus Engineering Reference document.

#### **1.13.13.1 Field: Name**

This is a unique name associated with the indoor swimming pool.

#### **1.13.13.2 Field: Surface Name**

This is the name of the surface (floor) where the pool is located. Pools are not allowed on any surfaces other than a floor.

#### **1.13.13.3 Field: Average Depth**

This field is the average depth of the pool in meters. If the pool has variable depth, the average depth should be specified to achieve the proper volume of water in the pool.

#### **1.13.13.4 Field: Activity Factor Schedule Name**

This field references a schedule that contains values for pool activity. This parameter can be varied using the schedule named here, and it has an impact on the amount of evaporation that will take place from the pool to the surrounding zone air. For example values of the activity factor and what impact it will have on the evaporation of water from the pool, please refer to indoor swimming pool section of the EnergyPlus Engineering Reference document. If left blank, the activity factor will be assumed to be unity.

#### **1.13.13.5 Field: Make-up Water Supply Schedule Name**

The scheduled named by this field establishes a cold water temperature [C] for the water that replaces the water which is lost from the pool due to evaporation. If blank, water temperatures are calculated by the Site:WaterMainsTemperature object. This field (even if blank) overrides the Cold Water Supply Temperature Schedule in all of the listed WaterUse:Equipment objects.

#### **1.13.13.6 Field: Cover Schedule Name**

This schedule defines when the pool water cover is available and affects the evaporation, convection, and radiation rate calculations. A schedule value of 0.0 means that the pool is not covered. A schedule value of 1.0 means the pool is 100% covered. The pool may be fully covered, fully open (uncovered), or partially covered (a value between 0.0 and 1.0). The user also has the option to control the evaporation, convection, short-wavelength radiation, and long-wavelength radiation factors when the pool is covered. These terms are discussed in the next four fields.

#### **1.13.13.7 Field: Cover Evaporation Factor**

This input field can optionally be used to modify the pool evaporation rate and is used in conjunction with the pool cover factor defined by the Pool Cover Schedule field (see above). The value for this parameter can normally range from 0.0 to 1.0, where 1 means that the pool cover completely eliminates evaporation from the pool surface, 0 means the pool cover has no effect on evaporation, and fractions in between 0 and 1 result in a fractional reduction in evaporation by the pool cover. So, if this parameter is 0.5 and the pool is 50% covered, the overall reduction in evaporation from a fully uncovered pool is 25% or 0.25.

#### **1.13.13.8 Field: Cover Convection Factor**

This input field can optionally be used to modify the pool convection rate and is used in conjunction with the pool cover factor defined by the Pool Cover Schedule field (see above). The value for this parameter can normally range from 0.0 to 1.0, where 1 means that the pool cover completely eliminates convection from the pool surface, 0 means the pool cover has no effect on convection, and fractions in between 0 and 1 result in a fractional reduction in convection by the pool cover. So, if this parameter is 0.5 and the pool is 50% covered, the overall reduction in convection from a fully uncovered pool is 25% or 0.25.

#### **1.13.13.9 Field: Cover Short-Wavelength Radiation Factor**

This input field can optionally be used to modify the pool short-wavelength radiation rate and is used in conjunction with the pool cover factor defined by the Pool Cover Schedule field (see above). The value for this parameter can normally range from 0.0 to 1.0, where 1 means that the pool cover completely eliminates short-wavelength radiation from the pool surface, 0 means the pool cover has no effect on short-wavelength radiation, and fractions in between 0 and 1 result in a fractional reduction in short-wavelength radiation by the pool cover. So, if this parameter is 0.5 and the pool is 50% covered, the overall reduction in short-wavelength radiation from a fully uncovered pool is 25% or 0.25. Note that with radiation terms that whatever portion of the short-wavelength radiation is blocked by the cover is transferred via convection to the surrounding zone air.

#### **1.13.13.10 Field: Cover Long-Wavelength Radiation Factor**

This input field can optionally be used to modify the pool long-wavelength radiation rate and is used in conjunction with the pool cover factor defined by the Pool Cover Schedule field (see above). The value for this parameter can normally range from 0.0 to 1.0, where 1 means that the pool cover completely eliminates long-wavelength radiation from the pool surface, 0 means the pool cover has no effect on long-wavelength radiation, and fractions in between 0 and 1 result in a fractional reduction in long-wavelength radiation by the pool cover. So, if this parameter is 0.5 and the pool is 50% covered, the overall reduction in long-wavelength radiation from a fully uncovered pool is 25% or 0.25. Note that with radiation terms that whatever portion of the long-wavelength radiation is blocked

by the cover is transferred via convection to the surrounding zone air.

#### 1.13.13.11 Field: Pool Water Inlet Node

This input is the name of the node on the demand side of a plant loop that leads into the pool. From the standpoint of an EnergyPlus input file, the pool sits on a plant demand loop, and the pump and heater reside on the plant supply loop. The pool heater and pump must be defined by other existing EnergyPlus input.

#### 1.13.13.12 Field: Pool Water Outlet Node

This input is the name of the node on the demand side of a plant loop that leads out of the pool. From the standpoint of an EnergyPlus input file, the pool sits on a plant demand loop, and the pump and heater reside on the plant supply loop. The pool heater and pump must be defined by other existing EnergyPlus input.

#### 1.13.13.13 Field: Pool Water Maximum Flow Rate

This input is the maximum water volumetric flow rate in m<sup>3</sup>/s going between the pool and the water heating equipment. This along with the pool setpoint temperature and the heating plant equipment outlet temperature will establish the maximum heat addition to the pool. This flow rate to the pool will be varied in an attempt to reach the desired pool water setpoint temperature (see Setpoint Temperature Schedule below).

#### 1.13.13.14 Field: Pool Miscellaneous Equipment Power

This input defines the power consumption rate of miscellaneous equipment such as the filtering and chlorination technology associated with the pool. The units for this input are in power consumption per flow rate of water through the pool from the heater or W/(kg/s). This field will be multiplied by the flow rate of water through the pool to determine the power consumption of this equipment. Any heat generated by this equipment is assumed to have no effect on the pool water itself.

#### 1.13.13.15 Field: Setpoint Temperature Schedule

Pools attempt to maintain a particular water temperature. In EnergyPlus, this field defines the setpoint temperature for the desired pool water temperature. It is input as a schedule to allow the user to vary the pool setpoint temperature as desired. The equipment defined to provide heating for the pool will deliver the necessary hot water to the pool, up to the capacity of that equipment defined by other input by the user.

#### 1.13.13.16 Field: Maximum Number of People

This field defines the maximum occupancy of people actually in the pool and thus will be used with the next two inputs to determine how much heat people contribute to the pool heat balance. People who are not in the pool should be modeled separately using the standard People description for zones.

#### 1.13.13.17 Field: People Schedule

This field defines a schedule that establishes how many people are in the pool at any given time. The current value of this schedule is multiplied by the maximum number of people in the previous field determines how many people are currently in the pool.

#### 1.13.13.18 Field: People Heat Gain Schedule

This field defines the amount of heat given off by an average person in the pool in Watts. This field is a schedule so that this heat gain can be allowed to vary as the type of activity in a pool can vary greatly and thus the amount of heat gain per person also varies. This parameter times the number of people in the pool determines how much heat is added to the pool. All heat given off by people is added to the heat balance of the pool water.

An example of an indoor swimming pool definition is:

- HVAC, Average, Indoor Pool Current Activity Factor []
- HVAC, Average, Indoor Pool Current Cover Factor []
- HVAC, Average, Indoor Pool Evaporative Heat Loss Rate [W]
- HVAC, Sum, Indoor Pool Evaporative Heat Loss Energy [J]

#### **1.13.14.1 Indoor Pool Makeup Water Rate [m3/s]**

The water consumption rate for the makeup water of indoor swimming pool.

#### **1.13.14.2 Indoor Pool Makeup Water Volume [m3]**

The water consumption for the makeup water of indoor swimming pool.

#### **1.13.14.3 Indoor Pool Makeup Water Temperature [C]**

The temperature of the makeup water of indoor swimming pool.

#### **1.13.14.4 Indoor Pool Water Temperature [C]**

The average calculated pool water temperature during the simulation at the time frequency requested.

#### **1.13.14.5 Indoor Pool Inlet Water Temperature [C]**

The temperature of the water being sent to the pool from the plant heating equipment.

#### **1.13.14.6 Indoor Pool Inlet Water Mass Flow Rate [kg/s]**

The mass flow rate of water being sent to the pool from the plant heating equipment. Typically this water is being passed through a heater and miscellaneous equipment.

#### **1.13.14.7 Indoor Pool Miscellaneous Equipment Power [W]**

The miscellaneous equipment power includes the power consumption of pool filter and chlorinator in Watts.

#### **1.13.14.8 Indoor Pool Miscellaneous Equipment Energy [J]**

The miscellaneous equipment power consumption includes the energy consumption of pool filter and chlorinator in Joules.

#### **1.13.14.9 Indoor Pool Heating Rate [W]**

This is the rate of heating provided by the plant loop to the pool in Watts.

#### **1.13.14.10 Indoor Pool Heating Energy [J]**

This is the amount of heating provided by the plant loop to the pool in Joules over the time step requested.

#### **1.13.14.11 Indoor Pool Radiant to Convection by Cover [W]**

The pool cover may block some or all of short- and long-wavelength radiation incident on the pool. To account for this and to not have the cover result in energy that is not accounted for by the model, the radiation that is blocked by the cover is converted to a convective gain (or loss) to/from the zone air. This output field reports this value.

#### **1.13.14.12 Indoor Pool Current Activity Factor []**

This is the current activity factor as defined by the user input schedule.

#### 1.13.14.13 Indoor Pool Current Cover Factor []

This is the current cover factor as defined by the user input schedule.

#### 1.13.14.14 Indoor Pool Evaporative Heat Loss Rate [W]

This is the rate of evaporative heat loss (latent) to the zone from the pool in Watts.

#### 1.13.14.15 Indoor Pool Evaporative Heat Loss Energy [J]

This is the amount of evaporative heat loss (latent) to the zone from the pool in Joules over the time step requested.

### 1.13.15 OtherEquipment

Other Equipment object is provided as an additional source for heat gains or losses directly to the zone. That is to say, a loss can be entered by putting a negative value into the Design Level field(s). Note, too, that this object does not have an end-use component – gains or losses do not show up in the bottom energy lines (except as influencing overall zone gains or losses).

#### 1.13.15.1 Field: Name

The name of the OtherEquipment object.

#### 1.13.15.2 Field: Zone or ZoneList Name

This field is the name of the thermal zone (ref: Zone) and attaches a particular other equipment statement to a thermal zone or set of thermal zones in the building. When the ZoneList option is used then this other equipment definition is applied to each of the zones in the zone list effecting a global definition for the amount of other in the zone. This option can be used effectively with the watts/area and watts/person options of the Design Level Calculation Method.

#### 1.13.15.3 Field: Schedule Name

This field is the name of the schedule that modifies the design level parameter for other equipment (see Design Level Calculation Method field and related subsequent fields). The schedule values can be any positive number. The actual energy input for other equipment in a zone as defined by this statement is the product of the design level field and the value of the schedule specified by name in this field.

#### 1.13.15.4 Field: Design Level Calculation Method

This field is a key/choice field that tells which of the next three fields are filled and is descriptive of the method for calculating the nominal other equipment level in the Zone. The key/choices are:

- EquipmentLevel

With this choice, the method used will be a straight insertion of the other equipment level (Watts) for the Zone. (The Design Level field should be filled.)

- Watts/Area or Power/Area

With this choice, the method used will be a factor per floor area of the zone. (The Power per Zone Floor Area field should be filled).

- Watts/Person or Power/Person

With this choice, the method used will be a factor of equipment level (watts) per person. (The Power per Person field should be filled).

#### 1.13.15.5 Field: Design Level

This field (in Watts) is typically used to represent the maximum energy input to other equipment in a zone that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the other equipment design level could be a “diversity factor” applied to a schedule of real numbers. This value can be negative to denote a loss. Note that while the schedule value can vary from hour to hour, the design level field is constant for all simulation environments.

#### 1.13.15.6 Field: Power per Zone Floor Area

This factor (watts/m<sup>2</sup>) is used, along with the Zone Area to determine the maximum equipment level as described in the Design Level field. This value can be negative to denote a loss. The choice from the method field should be “Watts/Area” or “Power/Area”.

#### 1.13.15.7 Field: Power per Person

This factor (watts/person) is used, along with the number of occupants (people) to determine the maximum equipment level as described in the Design Level field. This value can be negative to denote a loss. The choice from the method field should be “Watts/Person” or “Power/Person”.

#### 1.13.15.8 Heat Gains/Losses from Other Equipment:

The fuel input to the equipment ultimately appears as heat that contributes to zone loads. In EnergyPlus this heat is divided into four different fractions. Three of these are given by the input fields Fraction Latent, Fraction Radiant and Fraction Lost. A fourth, defined as the fraction of the heat from other equipment convected to the zone air, is calculated by the program as:

$$f_{\text{convected}} = 1.0 - (\text{Fraction Latent} + \text{Fraction Radiant} + \text{Fraction Lost})$$

You will get an error message if Fraction Latent + Fraction Radiant + Fraction Lost exceeds 1.0.

#### 1.13.15.9 Field: Fraction Latent

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of latent heat given off by other equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by other equipment to give the amount of latent energy produced by the other equipment. This energy affects the moisture balance within the zone.

#### 1.13.15.10 Field: Fraction Radiant

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of long-wave radiant heat being given off by other equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by other equipment to give the amount of long wavelength radiation gain from other equipment in a zone.

#### 1.13.15.11 Field: Fraction Lost

This field is a decimal number between 0.0 and 1.0 and is used to characterize the amount of "lost" heat being given off by other equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by other equipment to give the amount of heat which is "lost" and does not impact the zone energy balances. This might correspond to input energy converted to mechanical work or heat that is vented to the atmosphere.

- Zone,Average,Other Equipment Total Heating Rate [W]
- Zone,Sum,Zone Other Equipment Radiant Heating Energy [J]
- Zone,Average,Zone Other Equipment Radiant Heating Rate [W]
- Zone,Sum,Zone Other Equipment Convective Heating Energy [J]
- Zone,Average,Zone Other Equipment Convective Heating Rate [W]
- Zone,Sum,Zone Other Equipment Latent Gain Energy [J]
- Zone,Average,Zone Other Equipment Latent Gain Rate [W]
- Zone,Sum,Zone Other Equipment Lost Heat Energy [J]
- Zone,Average,Zone Other Equipment Lost Heat Rate [W]
- Zone,Sum,Zone Other Equipment Total Heating Energy [J]
- Zone,Average,Zone Other Equipment Total Heating Rate [W]

#### **1.13.16.1 Electric Equipment Electric Power [W]**

#### **1.13.16.2 Electric Equipment Electric Energy [J]**

The electric equipment electric power consumption in Watts (for power) or Joules (for energy). It is the sum of the radiant, convective, latent and lost components. This energy use is added to the electricity meters that are associated with the zone – Electricity:Facility, Electricity:Building, Electricity:Zone:<Zone Name>, InteriorEquipment:Electricity: :Zone:<Zone Name>, and <End-Use Subcategory>:InteriorEquipment:Electricity.

#### **1.13.16.3 Gas Equipment Gas Rate [W]**

#### **1.13.16.4 Gas Equipment Gas Energy [J]**

The gas equipment natural gas consumption in Watts (for power) or Joules (for energy). It is the sum of the radiant, convective, latent and lost components. This energy use is added to the electricity meters that are associated with the zone – Gas:Facility, Gas:Building, Gas:Zone:<Zone Name>, InteriorEquipment:Gas:

:Zone:<Zone Name>, and <End-Use Subcategory>:InteriorEquipment:Gas.

#### **1.13.16.5 Hot Water Equipment District Heating Rate [W]**

#### **1.13.16.6 Hot Water Equipment District Heating Energy [J]**

The hot water equipment district heating consumption in Watts (for power) or Joules (for energy). It is the sum of the radiant, convective, latent and lost components. This energy use is added to the district heating meters that are associated with the zone – DistrictHeating:Facility, DistrictHeating:Building, DistrictHeating:Zone:<Zone Name>, InteriorEquipment: DistrictHeating: :Zone:<Zone Name>, and <End-Use Subcategory>:InteriorEquipment: DistrictHeating.

#### **1.13.16.7 Steam Equipment District Heating Rate [W]**

#### **1.13.16.8 Steam Equipment District Heating Energy [J]**

The steam equipment district heating consumption in Watts (for power) or Joules (for energy). It is the sum of the radiant, convective, latent and lost components. This energy use is added to the district heating meters that are associated with the zone – DistrictHeating:Facility, DistrictHeating:Building, DistrictHeating:Zone:<Zone Name>, InteriorEquipment: DistrictHeating: :Zone:<Zone Name>, and <End-Use Subcategory>:InteriorEquipment: DistrictHeating.

Note that zone energy consumption is not reported for OTHER EQUIPMENT and does not go on any meter.

#### **1.13.17 ElectricEquipment:ITE:AirCooled**

This object describes air-cooled electric information technology equipment (ITE) which has variable power consumption as a function of loading and temperature.

##### **1.13.17.1 Field: Name**

The name of this object.

##### **1.13.17.2 Field: Zone Name**

This field is the name of the thermal zone (ref: Zone) which contains this ElectricEquipment:ITE:AirCooled object.

##### **1.13.17.3 Field: Design Power Input Calculation Method**

This field is a key/choice field that tells which of the next two fields are filled and is descriptive of the method for calculating the nominal electric power input to the ITE. The key/choices are:

Watts/Unit

With this choice, the design power input will be the product of Design Level per Unit and Number of Units. (Both of these fields should be filled.) This is the default.

Watts/Area

With this choice, the design power input will be a factor per floor area of the zone. (The Watts per Zone Floor Area field should be filled).

##### **1.13.17.4 Field: Watts per Unit**

This field (in Watts) is typically used to represent the design electrical power input to the ITE when fully loaded and the entering air temperatures is at the specified design value. This field is used if the choice from the method field is "EquipmentLevel".

##### **1.13.17.5 Field: Number of Units**

This field is multiplied times the Design Level per Unit to determine the design electrical power input to this ITE object when fully loaded and the entering air temperature is at the specified design value. This field is used if the choice from the method field is "EquipmentLevel". The default is 1.

##### **1.13.17.6 Field: Watts per Zone Floor Area**

This factor (Watts/m2) is used, along with the Zone Area to determine the design electrical power input as described in the Design Level field above. This field is used if the choice from the method field is "Watts/Area".

##### **1.13.17.7 Field: Design Power Input Schedule Name**

This field is the name of the operating schedule that modifies the design level power input for this equipment This schedule specifies the fraction (typically 0.0 to 1.0) of this equipment which is available (powered up), regardless of CPU utilization. If this field is blank, the schedule is assumed to always be 1.0.

##### **1.13.17.8 Field: CPU Loading Schedule Name**

This field is the name of the schedule that specifies the CPU loading for this equipment as a fraction from 0.0 (idle) to 1.0 (full load). If this field is blank, the

schedule is assumed to always be 1.0.

#### **1.13.17.9 Field: CPU Power Input Function of Loading and Air Temperature Curve Name**

The name of a two-variable curve or table lookup object which modifies the CPU power input as a function of CPU loading (x) and air inlet node temperature (y). This curve (table) should equal 1.0 at design conditions (CPU loading = 1.0 and Design Entering Air Temperature).

#### **1.13.17.10 Field: Design Fan Power Input Fraction**

This field is a decimal number between 0.0 and 1.0 and is used to specify the fraction of the total power input at design conditions which is for the cooling fan(s). If fan power data is not available, set this fraction to 0.0. The default is 0.0.

#### **1.13.17.11 Field: Design Fan Air Flow Rate per Power Input**

Specifies the cooling fan air flow rate in m3/s per Watt of total electric power input at design conditions (CPU loading = 1.0 and Design Entering Air Temperature).

This is normalized by power input to allow the design power input to be changed without needing to change this value.

#### **1.13.17.12 Field: Air Flow Function of Loading and Air Temperature Curve Name**

The name of a two-variable curve or table lookup object which modifies the cooling air flow rate as a function of CPU loading (x) and air inlet node temperature (y). This curve (table) should equal 1.0 at design conditions (CPU loading = 1.0 and Design Entering Air Temperature).

#### **1.13.17.13 Field: Fan Power Input Function of Flow Curve Name**

The name of a single-variable curve or table lookup object which modifies the fan power input as a function of airflow fraction (x). This curve (table) should equal 1.0 at the design air flow rate (flow fraction = 1.0).

#### **1.13.17.14 Field: Design Entering Air Temperature**

Specifies the entering air temperature in deg. C at design conditions. The default is 15C.

#### **1.13.17.15 Field: Environmental Class**

Specifies the allowable operating conditions for the air inlet conditions. The available inputs are A1, A2, A3, A4, B, C, or None. This is used to report the "ITE Air Inlet Operating Range Exceeded Time" If None is specified (the default), then no reporting of time outside allowable conditions will be done.

#### **1.13.17.16 Field: Air Inlet Connection Type**

Specifies the type of connection between the zone and the ITE air inlet node. The choices are:

AdjustedSupply = This option is used to apply a recirculation adjustment to the ITE inlet conditions. If this option is specified, then the Supply Air Node Name is required and the air inlet temperature to the ITE will be the current supply air node temperature adjusted by the current recirculation fraction. All heat output is added to the zone air heat balance as a convective gain. AdjustedSupply is the default.

ZoneAirNode = This option is used if there is no containment and the ITE air inlet node is at the average zone condition. All heat output is added to the zone air heat balance as a convective gain.

RoomAirModel = This option connects the ITE air inlet and outlet nodes to a room air model (Ref. RoomAirModelType and RoomAir:Node).

#### **1.13.17.17 Field: Air Inlet Room Air Model Node Name**

Specifies the name of a room air model node (ref. RoomAir:Node) which is the air inlet to this equipment. This field is required if the Air Node Connection Type = RoomAirModel.

#### **1.13.17.18 Field: Air Outlet Room Air Model Node Name**

Specifies the node name of a room air model node (ref. RoomAir:Node) which is the air outlet from this equipment. This field is required if the Air Node Connection Type = RoomAirModel.

#### **1.13.17.19 Field: Supply Air Node Name**

Specifies the node name of the supply air inlet node service this ITE. If the Air Node Connection Type = AdjustedSupply ,then this field is required, and the conditions at this node will be used to determine the ITE air inlet conditions. This field is also required if reporting of the Supply Heat Index is desired.

#### **1.13.17.20 Field: Design Recirculation Fraction**

Specifies the recirculation fraction for this equipment at design conditions. This field is used only if the Air Node Connection Type = AdjustedSupply. The recirculation fraction is defined as the ratio of recirculated air flow to total air flow entering the ITE. Recirculation is dependent upon many factors including rack and containment configuration. The default is 0.0 (no recirculation).

#### 1.13.17.21 Field: Recirculation Function of Loading and Supply Temperature Curve Name

The name of a two-variable curve or table lookup object which modifies the Design Recirculation Fraction as a function of CPU loading (x) and supply air node temperature (y). This curve (table) should equal 1.0 at design conditions (CPU loading = 1.0 and Design Entering Air Temperature). This field is used only if the Air Node Connection Type = AdjustedSupply. If this curve is left blank, then the curve is assumed to always equal 1.0.

#### 1.13.17.22 Field: Design Electric Power Supply Efficiency

This field is a decimal number used to specify the efficiency of the power supply system serving this ITE. The default is 1.0.

#### 1.13.17.23 Field: Electric Power Supply Efficiency Function of Part Load Ratio Curve Name

The name of a single-variable curve or table lookup object which modifies the electric power supply efficiency as a function of part load ratio (x). This curve (table) should equal 1.0 at the design power consumption (part load ratio = 1.0). If this curve is left blank, then the curve is assumed to always equal 1.0.

#### 1.13.17.24 Field: Fraction of Electric Power Supply Losses to Zone

This field is a decimal number between 0.0 and 1.0 and is used to specify the fraction of the electric power supply losses which are a heat gain to the zone containing the ITE. If this value is less than 1.0, the remainder of the losses are assumed to be lost to the outdoors. The default is 1.0.

#### 1.13.17.25 Field: CPU End-Use Subcategory

This equipment is metered on the Interior Equipment end-use category for Electricity. This field allows you to specify a user-defined end-use subcategory for the CPU power consumption. A new meter for reporting is created for each unique subcategory (ref: Output:Meter object). Subcategories are also reported in the ABUPS table. The default is ITE-CPU.

#### 1.13.17.26 Field: Fan End-Use Subcategory

This equipment is metered on the Interior Equipment end-use category for Electricity. This field allows you to specify a user-defined end-use subcategory for the fan power consumption. A new meter for reporting is created for each unique subcategory (ref: Output:Meter object). Subcategories are also reported in the ABUPS table. The default is ITE-Fans

#### 1.13.17.27 Field: Electric Power Supply End-Use Subcategory

This equipment is metered on the Interior Equipment end-use category for Electricity. This field allows you to specify a user-defined end-use subcategory for the electric power supply power consumption. A new meter for reporting is created for each unique subcategory (ref: Output:Meter object). Subcategories are also reported in the ABUPS table. The default is ITE-UPS

### 1.13.17.28 Zone ITE CPU Electric Power [W]

ITE CPU Electric Power [W]

**1.13.17.29 Zone ITE CPU Electric Energy [J]**

**1.13.17.30 ITE CPU Electric Energy [J]**

The electric power (or energy) input to the ITE equipment CPU (total power input less cooling fan power). The ITE CPU Electric Energy output is also added to a meter object with Resource Type = Electricity, End Use Key = InteriorEquipment, Group Key = Building (Ref. Output: Meter object).

**1.13.17.31 Zone ITE CPU Electric Power at Design Inlet Conditions [W]**

**1.13.17.32 ITE CPU Electric Power at Design Inlet Conditions [W]**

**1.13.17.33 Zone ITE CPU Electric Energy at Design Inlet Conditions [J]**

**1.13.17.34 ITE CPU Electric Energy at Design Inlet Conditions [J]**

The electric power (or energy) input to the ITE equipment CPU (total power input less cooling fan power) if the air inlet temperature were held at the design condition. May be used to calculate "IT efficiency", the ratio of (IT energy consumed in the facility) / (IT energy that would have been consumed in the facility if the ITE were held at the reference temperature).

**1.13.17.35 Zone ITE Fan Electric Power [W]**

**1.13.17.36 ITE Fan Electric Power [W]**

**1.13.17.37 Zone ITE Fan Electric Energy [J]**

**1.13.17.38 ITE Fan Electric Energy [J]**

The electric power (or energy) input to the ITE cooling fan. The ITE Fan Electric Energy output is also added to a meter object with Resource Type = Electricity, End Use Key = InteriorEquipment, Group Key = Building (Ref. Output: Meter object).

**1.13.17.39 Zone ITE Fan Electric Power at Design Inlet Conditions [W]**

**1.13.17.40 ITE Fan Electric Power at Design Inlet Conditions [W]**

**1.13.17.41 Zone ITE Fan Electric Energy at Design Inlet Conditions [J]**

**1.13.17.42 ITE Fan Electric Energy at Design Inlet Conditions [J]**

The electric power (or energy) input to the ITE cooling fan if the air inlet temperature were held at the design condition. May be used to calculate "IT efficiency", the ratio of (IT energy consumed in the facility) / (IT energy that would have been consumed in the facility if the ITE were held at the reference temperature).

**1.13.17.43 Zone ITE UPS Electric Power [W]**

**1.13.17.44 ITE UPS Electric Power [W]**

**1.13.17.45 Zone ITE UPS Electric Energy [J]**

**1.13.17.46 ITE UPS Electric Energy [J]**

The net electric power (or energy) input to the ITE equipment UPS (total power input less power delivered to ITE). The ITE UPS Electric Energy output is also added to a meter object with Resource Type = Electricity, End Use Key = InteriorEquipment, Group Key = Building (Ref. Output: Meter object).

**1.13.17.47 Zone ITE UPS Heat Gain to Zone Rate [W]**

**1.13.17.48 ITE UPS Heat Gain to Zone Rate [W]**

**1.13.17.49 Zone ITE UPS Heat Gain to Zone Energy [J]**

**1.13.17.50 ITE UPS Heat Gain to Zone Energy [J]**

The heat gain rate (or energy) to the zone from the UPS.

**1.13.17.51 Zone ITE Total Heat Gain to Zone Rate [W]**

**1.13.17.52 ITE Total Heat Gain to Zone Rate [W]**

### **1.13.17.53 Zone ITE Total Heat Gain to Zone Energy [J]**

### **1.13.17.54 ITE Total Heat Gain to Zone Energy [J]**

The heat gain rate (or energy) to the zone from the UPS and from the CPU and fans if the ITE. Air Inlet Connection Type is AdjustedSupply or ZoneAirNode. If RoomAirModel is selected, then only the heat gain from the UPS is added directly to the zone air heat balance, the heat gain from the CPU and fans will be added to the ITE air Outlet Room Air Model Node

### **1.13.17.55 Zone ITE Standard Density Air Volume Flow Rate [m3/s]**

### **1.13.17.56 ITE Standard Density Air Volume Flow Rate [m3/s]**

Reports the average air volume flow rate through the ITE over the reporting interval. Standard density in EnergyPlus corresponds to 20°C dry bulb, dry air, and nominally adjusted for elevation.

### **1.13.17.57 Zone ITE Current Density Air Volume Flow Rate [m3/s]**

### **1.13.17.58 ITE Current Density Air Volume Flow Rate [m3/s]**

Reports the average air volume flow rate through the ITE over the reporting interval, calculated using the current density at the air inlet node.

### **1.13.17.59 Zone ITE Air Mass Flow Rate [kg/s]**

### **1.13.17.60 ITE Air Mass Flow Rate [kg/s]**

Reports the average air mass flow rate through the ITE over the reporting interval, calculated using the current density at the air inlet node.

### **1.13.17.61 ITE Air Inlet Dry-Bulb Temperature [C]**

The dry-bulb temperature of the air entering the ITE.

### **1.13.17.62 ITE Air Inlet Dewpoint Temperature [C]**

The dewpoint temperature of the air entering the ITE.

### **1.13.17.63 ITE Air Inlet Relative Humidity [%]**

The dewpoint temperature of the air entering the ITE.

### **1.13.17.64 ITE Air Outlet Dry-Bulb Temperature [C]**

The dry-bulb temperature of the air leaving the ITE.

### **1.13.17.65 Zone ITE Average Supply Heat Index []**

### **1.13.17.66 ITE Supply Heat Index []**

The supply heat index (SHI) for this equipment. SHI is a dimensionless measure of recirculation of hot air into the cold air intake of the ITE.  $SHI = (T_{in} - T_{supply}) / (T_{out} - T_{supply})$  where  $T_{in}$  is the dry-bulb temperature of the air entering the ITE,  $T_{out}$  is the dry-bulb temperature of the air leaving the ITE, and  $T_{supply}$  is the dry-bulb temperature at the Supply Air Node. If a Supply Air Node Name is not specified for this object, then this output will not be reported.

### **1.13.17.67 Zone ITE Any Air Inlet Operating Range Exceeded Time [hr]**

### **1.13.17.68 ITE Air Inlet Operating Range Exceeded Time [hr]**

Hours when the dry-bulb and/or dewpoint temperature of the air entering the ITE is outside the range specified by the ITE Environmental Class.

### **1.13.17.69 Zone ITE Any Air Inlet Dry-Bulb Temperature Above Operating Range Time [hr]**

### **1.13.17.70 ITE Air Inlet Dry-Bulb Temperature Above Operating Range Time [hr]**

Hours when the dry-bulb temperature of the air entering the ITE is above the range specified by the ITE Environmental Class.

### **1.13.17.71 ITE Air Inlet Dry-Bulb Temperature Difference Above Operating Range [deltaC]**

The temperature difference (in degrees DeltaC) between the air inlet dry-bulb temperature and the maximum allowable dry-bulb temperature specified by the ITE Environmental Class. Only positive values are reported. When the dry-bulb temperature of the air entering the ITE is below the maximum specified by the ITE Environmental Class, this output will be zero.

#### **1.13.17.72 Zone ITE Any Air Inlet Dry-Bulb Temperature Below Operating Range Time [hr]**

#### **1.13.17.73 ITE Air Inlet Dry-Bulb Temperature Below Operating Range Time [hr]**

Hours when the dry-bulb temperature of the air entering the ITE is above the range specified by the ITE Environmental Class.

#### **1.13.17.74 ITE Air Inlet Dry-Bulb Temperature Difference Below Operating Range [deltaC]**

The temperature difference (in degrees DeltaC) between the air inlet dry-bulb temperature and the minimum allowable dry-bulb temperature specified by the ITE Environmental Class. Only negative values are reported. When the dry-bulb temperature of the air entering the ITE is above the minimum specified by the ITE Environmental Class, this output will be zero.

#### **1.13.17.75 Zone ITE Any Air Inlet Dewpoint Temperature Above Operating Range Time [hr]**

#### **1.13.17.76 ITE Air Inlet Dewpoint Temperature Above Operating Range Time [hr]**

Hours when the dewpoint temperature of the air entering the ITE is above the range specified by the ITE Environmental Class.

#### **1.13.17.77 ITE Air Inlet Dewpoint Temperature Difference Above Operating Range [deltaC]**

The temperature difference (in degrees DeltaC) between the air inlet dewpoint temperature and the maximum allowable dewpoint temperature specified by the ITE Environmental Class. Only positive values are reported. When the dewpoint temperature of the air entering the ITE is below the maximum specified by the ITE Environmental Class, this output will be zero.

#### **1.13.17.78 Zone ITE Any Air Inlet Dewpoint Temperature Below Operating Range Time [hr]**

#### **1.13.17.79 ITE Air Inlet Dewpoint Temperature Below Operating Range Time [hr]**

Hours when the dewpoint temperature of the air entering the ITE is above the range specified by the ITE Environmental Class.

#### **1.13.17.80 ITE Air Inlet Dewpoint Temperature Difference Below Operating Range [deltaC]**

The temperature difference (in degrees DeltaC) between the air inlet dewpoint temperature and the minimum allowable dewpoint temperature specified by the ITE Environmental Class. Only negative values are reported. When the dewpoint temperature of the air entering the ITE is above the minimum specified by the ITE Environmental Class, this output will be zero.

#### **1.13.17.81 Zone ITE Any Air Inlet Relative Humidity Above Operating Range Time [hr]**

#### **1.13.17.82 ITE Air Inlet Relative Humidity Above Operating Range Time [hr]**

Hours when the relative humidity of the air entering the ITE is above the range specified by the ITE Environmental Class.

#### **1.13.17.83 ITE Air Inlet Relative Humidity Difference Above Operating Range [%]**

The temperature difference (in degrees DeltaC) between the air inlet relative humidity and the maximum allowable relative humidity specified by the ITE Environmental Class. Only positive values are reported. When the relative humidity of the air entering the ITE is below the maximum specified by the ITE Environmental Class, this output will be zero.

#### **1.13.17.84 Zone ITE Any Air Inlet Relative Humidity Below Operating Range Time [hr]**

#### **1.13.17.85 ITE Air Inlet Relative Humidity Below Operating Range Time [hr]**

Hours when the relative humidity of the air entering the ITE is above the range specified by the ITE Environmental Class.

#### **1.13.17.86 ITE Air Inlet Relative Humidity Difference Below Operating Range [%]**

The temperature difference (in degrees DeltaC) between the air inlet relative humidity and the minimum allowable relative humidity specified by the ITE Environmental Class. Only negative values are reported. When the relative humidity of the air entering the ITE is above the minimum specified by the ITE Environmental Class, this output will be zero.

### **1.13.18 ZoneContaminantSourceAndSink:CarbonDioxide**

The ZoneContaminantSourceAndSink:CarbonDioxide object allows users to input carbon dioxide sources or sinks in a zone. Note that carbon dioxide generation within a zone can also be specified using People and GasEquipment objects. Multiple ZoneContaminantSourceAndSink:CarbonDioxide objects can be specified for the same zone.

#### **1.13.18.1 Field: Name**

The name of the ZoneContaminantSourceAndSink:CarbonDioxide object. The name for each ZoneContaminantSourceAndSink:CarbonDioxide object must be unique.

#### 1.13.18.2 Field: Zone Name

This field is the name of the zone (ref:Zone) and links a particular ZoneContaminantSourceAndSink:CarbonDioxide object to a thermal zone in the building.

#### 1.13.18.3 Field: Design Generation Rate

This field denotes the design carbon dioxide generation rate ( $\text{m}^3/\text{s}$ ). The design value is modified by the schedule fraction (see Field: Schedule Name). The resulting volumetric generation rate is converted to mass generation rate using the current zone indoor air density at each time step. The rate can be either positive or negative. A positive value represents a source rate ( $\text{CO}_2$  addition to the zone air) and a negative value represents a sink rate ( $\text{CO}_2$  removal from the zone air).

#### 1.13.18.4 Field: Schedule Name

This field is the name of the schedule (ref: Schedules) that modifies the design carbon dioxide generation rate (see previous field). The schedule values can be any positive number between 0.0 and 1.0. For each simulation time step, the actual  $\text{CO}_2$  generation rate in a zone is the product of the Design Generation Rate field (above) and the value specified by this schedule.

An IDF example is provided below:

```
ZoneContaminantSourceAndSink:CarbonDioxide,
  NORTH_ZONE CO2,          !- Name
  NORTH_ZONE,             !- Zone Name
  1.e-6,                  !- Design Generation Rate {m3/s}
  CO2 Source Schedule;    !- Schedule Name
```

### 1.13.19 ZoneContaminantSourceAndSink:CarbonDioxide Outputs

HVAC,Average, Contaminant Source or Sink  $\text{CO}_2$  Gain Volume Flow Rate [ $\text{m}^3/\text{s}$ ]

HVAC,Average, Zone Contaminant Source or Sink  $\text{CO}_2$  Gain Volume Flow Rate [ $\text{m}^3/\text{s}$ ]

#### 1.13.19.1 Contaminant Source or Sink $\text{CO}_2$ Gain Volume Flow Rate [ $\text{m}^3/\text{s}$ ]

This output is the net carbon dioxide internal gain/loss in  $\text{m}^3/\text{s}$  for an individual ZoneContaminantSourceAndSink:CarbonDioxide object.

#### 1.13.19.2 Zone Contaminant Source or Sink $\text{CO}_2$ Gain Volume Flow Rate [ $\text{m}^3/\text{s}$ ]

This output variable reports the total (net) carbon dioxide internal gains/losses in cubic meters per second for a zone, including impacts from three objects: ZoneContaminantSourceAndSink:CarbonDioxide, People, and GasEquipment. Positive values denote carbon dioxide generation (gain or source), while negative values denote carbon dioxide removal (loss or sink).

### 1.13.20 ZoneContaminantSourceAndSink:GenericContaminant:Constant

The ZoneContaminantSourceAndSink:GenericContaminant:Constant object specifies the generic contaminant generation rate and removal rate coefficient in a zone. The associated fraction schedules are required for allowing users to change the magnitude of sources and sinks. The object is equivalent to the combination of the constant coefficient model and the burst source model defined in the sources and sinks element types of CONTAM 3.0. The basic equation used to calculate generic contaminant source and sink for the constant model is given below:

$$S_f(t) = G_f(t) * F_G - R_f(t)C_f(t) * 1.0E - 6 * F_R \quad (19)$$

where

$S_f$  = Contaminant generic contaminant source strength [ $\text{m}^3/\text{s}$ ]

$G_f$  = Generic contaminant generation rate [ $\text{m}^3/\text{s}$ ]

$F_G$  = Fraction value from the source fraction schedule at a given time [dimensionless]

$R_f$  = Generic contaminant effective removal rate [ $\text{m}^3/\text{s}$ ]

$F_R$  = Fraction value from the sink fraction schedule at a given time [dimensionless]

$C_f$  = Generic contaminant concentration value at a given previous time step [ppm]

#### 1.13.20.1 Field: Name

This field represents a unique identifying name in a group referring Generic contaminantSourceAndSinkNames.

#### 1.13.20.2 Field: Zone Name

This field signifies the Name of the zone with constant generic contaminant source and sink.

#### 1.13.20.3 Field: Maximum Generation Rate

This field denotes the full generic contaminant maximum generation rate ( $\text{m}^3/\text{s}$ ). The design generation rate is the maximum amount of generic contaminant expected at design conditions. The design value is modified by the schedule fraction (see Field:Generation Schedule Name).

#### 1.13.20.4 Field: Generation Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design generation rate ( $\dot{Q}$ ). This fraction between 0.0 and 1.0 is noted as  $F_G$  in the above equation.

#### 1.13.20.5 Field: Design Removal Coefficient

This field denotes the full generic contaminant design removal coefficient ( $\text{m}^3/\text{s}$ ). The design removal rate is the maximum amount of generic contaminant expected at design conditions times the generic contaminant concentration in the same zone. The design value is modified by the schedule fraction (see Field:Removal Schedule Name).

#### 1.13.20.6 Field: Removal Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design generation rate ( $\dot{R}$ ). This fraction between 0.0 and 1.0 is noted as  $F_R$  in the above equation.

An IDF example is provided below:

```
ZoneContaminantSourceAndSink:GenericContaminant:Constant,
NORTH ZONE GC,           !- Name
NORTH ZONE,             !- Zone Name
1.0E-6,                 !- Design Generation Rate {m3/s}
GC Source Schedule,     !- Schedule Name
1.0E-7,                 !- Design Removal Coefficient {m3/s}
GC Removal Schedule;    !- Removal Schedule Name
```

### 1.13.21 ZoneContaminantSourceAndSink:GenericContaminant:Constant Outputs

When a ZoneContaminantSourceAndSink:GenericContaminant:Constant object is specified, the following output variables are available:

ZONE,Average, Generic Air Contaminant Constant Source Generation Volume Flow Rate [m3/s]

#### 1.13.21.1 Generic Air Contaminant Constant Source Generation Volume Flow Rate [m3/s]

This output is the average generic contaminant generation rate from each ZoneContaminantSourceAndSink:GenericContaminant:Constant object. The generation rate is a sum of generation and removal rates. The zone air generic contaminant level at the previous zone time step is used in the removal rate calculation.

### 1.13.22 SurfaceContaminantSourceAndSink:GenericContaminant:PressureDriven

The SurfaceContaminantSourceAndSink:GenericContaminant:PressureDriven object specifies the generic contaminant generation rate coefficient, which is used to calculate the generation rate due to the pressure difference across the surface. The object is equivalent to the pressure driven model defined in the sources and sinks element types of CONTAM 3.0. This object assumes to work with the AirflowNetwork model. The surface has to be defined in the AirflowNetwork:Multizone:Surface. Although the model is designed to be applied to radon and soil gas entry, it is expanded to be applied to all contaminant transport, including generic contaminant. However, it should be used in caution. The basic equation used to calculate generic contaminant source for the pressure driven constant model is provided below:

$$S_f(t) = H_f(t) * F_G * (P_j - P_i)^n \quad (20)$$

where

$S_f$  = Generic contaminant source strength [ $\text{m}^3/\text{s}$ ]

$H_f$  = Generic contaminant generation rate coefficient [ $\text{m}^3/\text{s}$ ]

$F_G$  = Fraction value from the source fraction schedule at a given time [dimensionless]

$n$  = Flow power exponent

$P_i$  = Zone pressure [Pa]

$P_j$  = Pressure in an adjacent zone for a interior surface or outdoor for an exterior surface [Pa]

#### 1.13.22.1 Field: Name

The field signifies the unique identifying name in a group referring GenericContaminantSourceAndSinkNames.

#### 1.13.22.2 Field: Surface Name

This field represents the name of the surface as a generic contaminant source using the pressure driven model.

#### 1.13.22.3 Field: Design Generation Rate Coefficient

This field denotes the generic contaminant design generation coefficient ( $m^3/s$ ). The design generation rate is the maximum amount of generic contaminant expected at design conditions times the pressure difference with a power exponent across a surface. The design value is modified by the schedule fraction (see Field:Generation Schedule Name).

#### 1.13.22.4 Field: Generation Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design generation rate. This fraction between 0.0 and 1.0 is noted as  $\xi$  in the above equation.

An IDF example is provided below:

```
SurfaceContaminantSourceAndSink:GenericContaminant:PressureDriven,  
WEST ZONE GC BLD,           !- Name  
Zn001:Wall001,             !- Surface Name  
1.0E-6,                    !- Design Generation Rate Coefficient {m3/s}  
GC Source Schedule,        !- Generation Schedule Name  
0.5;                       !- Generation Exponent
```

### 1.13.23 SurfaceContaminantSourceAndSink:GenericContaminant:PressureDriven Outputs

When a SurfaceContaminantSourceAndSink:GenericContaminant:PressureDriven object is specified, the following output variables are available:

ZONE,Average,Generic Air Contaminant Pressure Driven Generation Volume Flow Rate [m3/s]

#### 1.13.23.1 Generic Air Contaminant Pressure Driven Generation Volume Flow Rate [m3/s]

This output is the average generic contaminant generation rate from each SurfaceContaminantSourceAndSink:GenericContaminant:PressureDriven object.

### 1.13.24 ZoneContaminantSourceAndSink:GenericContaminant:CutoffModel

The ZoneContaminantSourceAndSink:Generic contaminant:CutoffModel object specifies the generic contaminant generation rate based on the cutoff concentration model. The basic equation used to calculate generic contaminant source for the pressure driven constant model is given below:

$$S_f(t) = \begin{cases} G_f(t) * F_G * \left(1 - \frac{C_f(t)}{C_{cutoff}}\right) & C_f < C_{cutoff} \\ 0 & C_f \geq C_{cutoff} \end{cases} \quad (21)$$

where

$S_f$  = Generic contaminant source strength [ $m^3/s$ ]

$G_f$  = Generic contaminant generation rate [ $m^3/s$ ]

$F_G$  = Fraction value from the source fraction schedule at a given time [dimensionless]

$C_{cutoff}$  = Cutoff concentration at which emission ceases [ppm]

$C_f$  = Generic contaminant concentration value at a given previous time step [ppm]

#### 1.13.24.1 Field: Name

The field signifies the unique identifying name in a group referring GenericContaminantSourceAndSinkNames.

#### 1.13.24.2 Field: Zone Name

This field represents the name of the zone with generic contaminant source and sink using the cutoff model.

### 1.13.24.3 Field: Design Generation Rate

This field denotes the full generic contaminant design generation rate ( $m^3/s$ ). The design generation rate is the maximum amount of generic contaminant expected at design conditions. The design value is modified by the schedule fraction (see Field:Generation Schedule Name).

### 1.13.24.4 Field: Generation Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design generation rate ( $G$ ). This fraction between 0.0 and 1.0 is noted as  $F_G$  in the above equation.

### 1.13.24.5 Field: Cutoff Concentration

This field is the generic contaminant cutoff concentration level where the source ceases its emission.

An IDF example is provided below:

```
ZoneContaminantSourceAndSink:GenericContaminant:CutoffModel,
  NORTH ZONE GC CutoffModel,          !- Name
  NORTH ZONE,                          !- Zone Name
  1.0E-5,                                !- Design Generation Rate {m3/s}
  GC Source Schedule,                  !- Schedule Name
  100000;                                !- Cutoff Concentration {ppm}
```

### 1.13.25 ZoneContaminantSourceAndSink:GenericContaminant:CutoffModel Outputs

When a ZoneContaminantSourceAndSink:GenericContaminant:CutoffModel object is specified, the following output variables are available:

ZONE,Average, Generic Air Contaminant Cutoff Model Generation Volume Flow Rate [m3/s]

#### 1.13.25.1 Generic Air Contaminant Cutoff Model Generation Volume Flow Rate [m3/s]

This output is the average generic contaminant generation rate from each SurfaceContaminantSourceAndSink:GenericContaminant: CutoffModel object.

### 1.13.26 ZoneContaminantSourceAndSink:GenericContaminant:DecaySource

The ZoneContaminantSourceAndSink:GenericContaminant:DecaySource object specifies the generic contaminant generation rate based on the decay source model. The basic equation used to calculate generic contaminant source for the decay source model is given below:

$$S_f(t) = G_f(t)F_G \exp(-t/t_c) \quad (22)$$

where

$S_f$  = Generic contaminant source strength [ $m^3/s$ ]

$G_f$  = Initial generic contaminant generation rate [ $m^3/s$ ]

$F_G$  = Fraction value from the source fraction schedule at a given time [dimensionless]

$t$  = Time since the start of emission [second]

$t_c$  = Decay time constant [second]

#### 1.13.26.1 Field: Name

This field is the unique identifying name in a group referring GenericContaminantSourceAndSinkNames.

#### 1.13.26.2 Field: Zone Name

This field represents the name of the zone with a generic contaminant decaying source.

#### 1.13.26.3 Field: Initial Generation Rate

This field denotes the initial generic contaminant design generation rate ( $m^3/s$ ). The generation is controlled by a schedule, as defined in the next field. Generic contaminant generation begins when the schedule changes from a zero to a non-zero value (between zero and one). The initial generation rate is equal to the schedule value times the initial generation rate. A single schedule may be used to initiate several emissions at different times.(see Field:Generation Schedule Name).

#### 1.13.26.4 Field: Generation Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design generation rate ( $\mathbb{G}$ ). This fraction between 0.0 and 1.0 is noted as  $F_G$  in the above equation. When the value is equal to 1, the generation rate is used and time is reset to zero. When the value is equal to zero, the schedule value is ignored in the equation.

### 1.13.26.5 Field: Decay Time Constant

This field is the time at which the generation rate reaches 0.37 of the original rate.

Note: The variable  $t$ , time since the start of emission, will be reset to zero, when a new run period starts, or the generation schedule value is equal to zero.

An IDF example is provided below:

```
ZoneContaminantSourceAndSink:GenericContaminant:DecaySource,
WEST ZONE GC DecaySource,      !- Name
WEST ZONE,                    !- Zone Name
1.0E-5,                        !- Initial Emission Rate {m3/s}
GC Source Schedule,          !- Schedule Name
100000;                        !- Delay Time Constant {s}
```

### 1.13.27 ZoneContaminantSourceAndSink:GenericContaminant:DecaySource Outputs

When a ZoneContaminantSourceAndSink:GenericContaminant:DecaySource object is specified, the following output variables are available:

Zone,Average,Generic Air Contaminant Decay Model Generation Volume Flow Rate [m3/s]

Zone,Average,Generic Air Contaminant Decay Model Generation Emission Start Elapsed Time [s]

#### 1.13.27.1 Generic Air Contaminant Decay Model Generation Volume Flow Rate [m3/s]

This output is the average generic contaminant decay rate from each SurfaceContaminantSourceAndSink:GenericContaminant:DecaySource object.

#### 1.13.27.2 Generic Air Contaminant Decay Model Generation Emission Start Elapsed Time [s]

This output is the decay time since the start of emission. The start time is either at the beginning of each run period, including design day simulations, or the time when the egeneration schedule value is zero.

### 1.13.28 SurfaceContaminantSourceAndSink:GenericContaminant:BoudaryLayerDiffusion

The SurfaceContaminantSourceAndSink:GenericContaminant:BoudaryLayerDiffusion object specifies the generic contaminant generation rate from surface diffusion. The object is equivalent to the boundary layer diffusion model driven model defined in the sources and sinks element types of CONTAM 3.0.

The boundary layer diffusion controlled reversible sink/source model with a linear sorption isotherm follows the descriptions presented in [Axley 1991]. The boundary layer refers to the region above the surface of a material through which a concentration gradient exists between the near-surface concentration and the air-phase concentration. The rate at which a contaminant is transferred onto a surface (sink) is defined as:

$$S_f = h * \rho * A \left( C_f - \frac{C_s}{k} \right) * 1.0E - 6 \quad (23)$$

where

$h$  = Average film mass transfer coefficient over the sink [m/s]

$\rho$  = Film density of air [kg/m<sup>3</sup>]

$A$  = Surface area of the adsorbent [m<sup>2</sup>]

$C_f$  = Concentration in the air at the previous time step [ppm]

$C_s$  = Concentration in the adsorbent [ppm]

$k$  = Henry adsorption constant or partition coefficient [dimensionless]

#### 1.13.28.1 Field: Name

This field signifies a unique identifying name in a group referring GenericContaminanteSourceAndSinkNames.

#### 1.13.28.2 Field: Surface Name

This field denotes the name of the surface as a generic contaminant reversible source or sink using the boundary layer diffusion model.

#### 1.13.28.3 Field: Film Transfer Coefficient

This field specifies the average mass transfer coefficient of the contaminant generic contaminant within the boundary layer (or film) above the surface of the adsorbent.

#### 1.13.28.4 Field: Henry Partition Coefficient

This field denotes the generic contaminant Henry partition coefficient in the units of dimensionless. The coefficient relates the concentration of the contaminant generic contaminant in the bulk-air to that at the surface of the adsorption material.

An IDF example is provided below:

```
SurfaceContaminantSourceAndSink:GenericContaminant:BoudaryLayerDiffusion,
WEST ZONE GC BLD,          !- Name
Zn001:Wall001,            !- Surface Name
1.0E-2,                   !- Mass Transfer Coefficient {m/s}
GC Source Schedule,       !- Schedule Name
2.0;                      !- Henry adsorption constant or partition coefficient
```

#### 1.13.29 SurfaceContaminantSourceAndSink:GenericContaminant:BoundaryLayerDiffusion Outputs

When a SurfaceContaminantSourceAndSink:GenericContaminant:BoudaryLayerDiffusion object is specified, the following output variables are available:

ZONE,Average, Generic Air Contaminant Boundary Layer Diffusion Generation Volume Flow Rate [m3/s]

ZONE,Average, Generic Air Contaminant Boundary Layer Diffusion Inside Face Concentration [ppm]

##### 1.13.29.1 Generic Air Contaminant Boundary Layer Diffusion Generation Volume Flow Rate [m3/s]

This output is the average generic contaminant generation rate from each SurfaceContaminantSourceAndSink:GenericContaminant:BoudaryLayerDiffusion object.

##### 1.13.29.2 Generic Air Contaminant Boundary Layer Diffusion Inside Face Concentration [ppm]

This output is the average generic contaminant level at the interior surface.

#### 1.13.30 SurfaceContaminantSourceAndSink:GenericContaminant:DepositionVelocitySink

The SurfaceContaminantSourceAndSink:GenericContaminant:DepositionVelocitySink object specifies the generic contaminant removal rate from a surface. The object is equivalent to the deposition velocity sink model defined in CONTAM 3.0 sources and sinks element types.

The deposition velocity model provides for the input of a sink's characteristic in the familiar term of deposition velocity. The removal stops when the sink concentration level is higher than the zone air concentration level. The deposition velocity model equation is:

$$S_f(t) = \nu_d A_s m * C_f(t) * 1.0E - 6 * F_R \quad (24)$$

where

$S_f(t)$  = Removal rate at time t [m<sup>3</sup>/s]

$\nu_d$  = Deposition velocity [m/s]

$A_s$  = Deposition surface area [m<sup>2</sup>]

$m$  = Element multiplier [dimensionless]

$C_f(t)$  = Concentration of contaminant generic contaminant at the previous time step [ppm]

$F_R$  = Schedule or control signal value at time t [-]

##### 1.13.30.1 Field: Name

This field denotes a unique identifying name in a group referring GenericContaminant SourceAndSinkNames.

##### 1.13.30.2 Field: Surface Name

This field represents the name of the surface as a generic contaminant sink using the deposition velocity sink model.

##### 1.13.30.3 Field: Deposition Velocity

This field specifies the deposition velocity to the surface of the adsorbent in the units of m/s.

##### 1.13.30.4 Field: Removal Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design removal rate ( $\Phi$ ). This fraction between 0.0 and 1.0 is noted as  $F_R$  in the above equation.

An IDF example is provided below:

```
SurfaceContaminantSourceAndSink:GenericContaminant:DepositionVelocitySink,
  EAST_ZONE_GC_DVS,      !- Name
  Zn002:Wall001,        !- Surface Name
  1.0E-3,                !- Deposition Velocity {m/s}
  GC_Source_Schedule;    !- Schedule Name
```

### 1.13.31 SurfaceContaminantSourceAndSink:GenericContaminant:DepositionVelocitySink Outputs

The following output variables are available when the SurfaceContaminantSourceAndSink:GenericContaminant:DepositionVelocitySink object is specified.

ZONE,Average, Generic Air Contaminant Deposition Velocity Removal Volume Flow Rate [m3/s]

#### 1.13.31.1 Generic Air Contaminant Deposition Velocity Removal Volume Flow Rate [m3/s]

This output is the average generic contaminant generation rate from each SurfaceContaminantSourceAndSink:GenericContaminant:DepositionVelocitySink object.

### 1.13.32 ZoneContaminantSourceAndSink:GenericContaminant:DepositionRateSink

The ZoneContaminantSourceAndSink:GenericContaminant:DepositionRateSink object specifies the generic contaminant removal rate from a zone. The object is equivalent to the deposition rate sink model defined in CONTAM 3.0 sources and sinks element types.

The deposition rate model provides for the input of a sink's characteristic in the familiar term of deposition rate in a zone. The removal stops when the sink concentration level is higher than the zone air concentration level. The deposition rate model equation is:

$$S_f(t) = k_d V_z * C_f(t) * 1.0E - 6 * F_R m \quad (25)$$

Where

$S_f(t)$  = Removal rate at time  $t$  [ $m^3/s$ ]

$k_d$  = Deposition rate [1/T]

$V_z$  = Zone volume [ $m^3$ ]

$m$  = Element multiplier [dimensionless]

$C_f(t)$  = Concentration of generic contaminant at the previous timestep [ppm]

$F_R$  = Schedule or control signal value at time  $t$  [dimensionless]

#### 1.13.32.1 Field: Name

This field denotes a unique identifying name in a group referring GenericContaminantSourceAndSinkNames.

#### 1.13.32.2 Field: Zone Name

This field represents the name of the zone as a generic contaminant sink using the deposition rate sink model.

#### 1.13.32.3 Field: Deposition Rate

This field specifies the deposition rate to the zone in the units of 1/s.

#### 1.13.32.4 Field: Removal Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design removal rate ( $\Phi$ ). This fraction between 0.0 and 1.0 is noted as  $F_R$  in the above equation.

An IDF example is provided below:

```
ZoneContaminantSourceAndSink:GenericContaminant:DepositionRateSink,
  NORTH_ZONE_GC_DRS,    !- Name
  NORTH_ZONE,           !- Zone Name
  1.0E-5,                !- Deposition Rate {m3/s}
  GC_Source_Schedule;    !- Schedule Name
```

### 1.13.33 ZoneContaminantSourceAndSink:GenericContaminant:DepositionRateSink Outputs

When the ZoneContaminantSourceAndSink:GenericContaminant:DepositionRateSink object is specified, the following output variables are available:

ZONE,Average, Generic Air Contaminant Deposition Rate Removal Volume Flow Rate [m3/s]

#### 1.13.33.1 Generic Air Contaminant Deposition Rate Removal Volume Flow Rate [m3/s]

This output is the average generic contaminant generation rate from each ZoneContaminantSourceAndSink:GenericContaminant:DepositionRateSink object.

### 1.13.34 ZoneBaseboard:OutdoorTemperatureControlled

This object specifies outside temperature-controlled (OTC) baseboard heating. The capacities (high and low) are specified in W at the temperatures specified. The schedule allows both capacities to change hourly on a proportional basis. This baseboard heater does not operate if the outdoor dry-bulb is above the high temperature limit. Between the high temperature and the low temperature, the capacity is interpolated (linear) between the high and the low capacity values. Below the low temperature, the capacity is set at the low capacity value. This allows the user to add baseboard heat to a perimeter zone starting at a prescribed temperature and then slowly increases this capacity to a max value.

#### Example:

Temperature High = 10 C    Capacity High = 100,000 W

Temperature Low = 0 C    Capacity Low = 500,000 W

Table 16. Outdoor Temperature Controlled Baseboard Heat Temperature vs. Capacity

Outdoor Dry-bulb(C)	Baseboard Output
>10	0
10	100,000
8	180,000
6	260,000
4	340,000
2	420,000
0	500,000
< 0	500,000

#### 1.13.34.1 Field: Name

The name of the ZoneBaseboard:OutdoorTemperatureControlled object.

#### 1.13.34.2 Field: Zone Name

This field is the name of the zone and attaches the baseboard heat equipment statement to a thermal zone in the building.

#### 1.13.34.3 Field: Schedule Name

This field is the name of the schedule that modifies the capacities (high and low) for baseboard heat equipment (see next four fields). The schedule values can be any positive number. The actual energy input for the baseboard equipment in a zone as defined by this statement depends on the actual outdoor temperature and where that temperature is in the range of Low Temperature to High Temperature..

#### 1.13.34.4 Field: Capacity at Low Temperature

This is the baseboard equipment capacity (Watts) at the low temperature limit. This is the maximum capacity of the baseboard equipment in full load operation. This field is autosizable.

#### 1.13.34.5 Field: Low Temperature

If the outdoor dry-bulb temperature (degrees Celsius) is at or below the low temperature the baseboard heater operates at the low temperature capacity. This field is autosizable. The lowest design outdoor dry bulb temperature is chosen, if autosized.

#### 1.13.34.6 Field: Capacity at High Temperature

This is the baseboard equipment capacity (Watts) at the high temperature limit. This field is autosizable. The capacity at low temperature is prorated against the reference low and high temperature fields, if autosized.

### 1.13.34.7 Field: High Temperature

If the outdoor dry-bulb temperature (degrees Celsius) is greater than the high temperature the baseboard heater will not operate. This field is autosizable. If autosized, this is equal to the design zone heating setpoint temperature described below, so that the capacity at high temperature is zero.

### 1.13.34.8 Field: Fraction Radiant

This field is a decimal number between 0.0 and 1.0 and is used to characterize the type of heat being given off by baseboard heat equipment in a zone. The number specified in this field will be multiplied by the total energy consumed by the baseboard heat equipment to give the amount of long wavelength radiation gain to the zone.

### 1.13.34.9 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Perimeter Baseboards", etc. A new meter for reporting is created for each unique subcategory (ref: Output:Meter objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the baseboard equipment will be assigned to the "General" end-use subcategory.

### 1.13.34.10 Field: Design Zone Heating Setpoint

This is heating setpoint temperature in the zone where the unit serves. This is used to autosize high temperature and capacity at high temperature fields. The default value is 20°C.

An IDF example:

```
ZoneBaseboard:OutdoorTemperatureControlled,
  SPACE4-1 BBHeat 1,      !- Name
  SPACE4-1,              !- Zone Name
  EQUIP-1,               !- SCHEDULE Name
  1500,                  !- Capacity at low temperature {W}
  0,                     !- Low Temperature {C}
  500,                   !- Capacity at high temperature {W}
  10,                    !- High Temperature {C}
  0.5,                   !- Fraction Radiant
  Baseboard Heat,       !- End-Use Subcategory
  20;                    !- Design Zone Heating Setpoint
```

{C}

## 1.13.35 ZoneBaseboard:OutdoorTemperatureControlled Output

ZoneBaseboard:OutdoorTemperatureControlled objects have output variables for individual objects and for zone totals. The following outputs are available:

- Zone,Average,Baseboard Electric Power [W]
- Zone,Sum,Baseboard Electric Energy [J]
- Zone,Sum,Baseboard Radiant Heating Energy [J]
- Zone,Average,Baseboard Radiant Heating Rate [W]
- Zone,Sum,Baseboard Convective Heating Energy [J]
- Zone,Average,Baseboard Convective Heating Rate [W]
- Zone,Sum,Baseboard Total Heating Energy [J]
- Zone,Average,Baseboard Total Heating Rate [W]
- Zone,Average,Zone Baseboard Electric Power [W]
- Zone,Sum,Zone Baseboard Electric Energy [J]
- Zone,Sum,Zone Baseboard Radiant Heating Energy [J]
- Zone,Average,Zone Baseboard Radiant Heating Rate [W]
- Zone,Sum,Zone Baseboard Convective Heating Energy [J]
- Zone,Average,Zone Baseboard Convective Heating Rate [W]
- Zone,Sum,Zone Baseboard Total Heating Energy [J]
- Zone,Average,Zone Baseboard Total Heating Rate [W]

### **1.13.35.1 Baseboard Electric Power [W]**

This field is the electric power for the ZoneBaseboard:OutdoorTemperatureControlled object in Watts.

### **1.13.35.2 Baseboard Electric Energy [J]**

The outdoor temperature controlled baseboard heat option is assumed to be fueled by electricity. This field is the same as the Baseboard Total Heating Energy (above) in joules.

### **1.13.35.3 Baseboard Radiant Heating Rate [W]**

### **1.13.35.4 Baseboard Radiant Heating Energy [J]**

These output variables are the amount of radiant heat gain for the ZoneBaseboard:OutdoorTemperatureControlled object in Watts (for rate) or Joules. This is determined by the current heat gain from the heater to the zone and the "Fraction Radiant" specified in the input. The radiant gains (long wavelength) are distributed to the surfaces using an area weighting scheme.

### **1.13.35.5 Baseboard Convective Heating Rate [W]**

### **1.13.35.6 Baseboard Convective Heating Energy [J]**

These output variables are the amount of convective heat gain for the ZoneBaseboard:OutdoorTemperatureControlled object in Watts (for rate) or Joules. This is determined by the current heat gain from the heater to the zone and the "Fraction Radiant" specified in input ( $1 - \text{FractionRadiant} = \text{FractionConvected}$ ). The convective heat gain is added to the zone air heat balance directly.

### **1.13.35.7 Baseboard Total Heating Rate [W]**

### **1.13.35.8 Baseboard Total Heating Energy [J]**

These output variables are the amount of heat gain for the ZoneBaseboard:OutdoorTemperatureControlled object in Watts (for rate) or Joules. This is determined by the sum of the radiant and convective heat gains from the baseboard heat.

### **1.13.35.9 Zone Baseboard Electric Power [W]**

This field is the electric power for all ZoneBaseboard:OutdoorTemperatureControlled objects within the zone in Watts.

### **1.13.35.10 Zone Baseboard Electric Energy [J]**

The outdoor temperature controlled baseboard heat option is assumed to be fueled by electricity. This field is the same as the Baseboard Total Heating Energy (above) in joules. However, this amount is also shown in the Electricity meters that are associated with the zone – Electricity:Facility, Electricity:Building, Electricity:Zone:<Zone Name>, and InteriorEquipment:Electricity.

### **1.13.35.11 Zone Baseboard Radiant Heating Rate [W]**

### **1.13.35.12 Zone Baseboard Radiant Heating Energy [J]**

These output variables are the amount of radiant heat gain for all ZoneBaseboard:OutdoorTemperatureControlled objects within the zone in Watts (for rate) or Joules. This is determined by the current heat gain from the heater to the zone and the "Fraction Radiant" specified in the input. The radiant gains (long wavelength) are distributed to the surfaces using an area weighting scheme.

### **1.13.35.13 Zone Baseboard Convective Heating Rate [W]**

### **1.13.35.14 Zone Baseboard Convective Heating Energy [J]**

These output variables are the amount of convective heat gain for all ZoneBaseboard:OutdoorTemperatureControlled objects within the zone in Watts (for rate) or Joules. This is determined by the current heat gain from the heater to the zone and the "Fraction Radiant" specified in input ( $1 - \text{FractionRadiant} = \text{FractionConvected}$ ). The convective heat gain is added to the zone air heat balance directly.

### **1.13.35.15 Zone Baseboard Total Heating Rate [W]**

### **1.13.35.16 Zone Baseboard Total Heating Energy [J]**

These output variables are the amount of heat gain for all ZoneBaseboard:OutdoorTemperatureControlled objects within the zone in Watts (for rate) or Joules. This is determined by the sum of the radiant and convective heat gains from the baseboard heat.

## **1.13.36 Meters for Equipment Outputs**

As described in each of the equipment sections, values for specific equipments will show up on the following meters:

Table 17. Distribution of Equipment to Meters

Meter Name	Scope	Equipment Specifics
Electricity:Facility	Entire Facility	Electric Equipment, OTC Baseboard Heat
Electricity:Building	All Zones	Electric Equipment, OTC Baseboard Heat
Electricity:Zone:<Zone Name>	Specific Zone	Electric Equipment, OTC Baseboard Heat
InteriorEquipment:Electricity	AllZones	Electric Equipment, OTC Baseboard Heat
<End-Use Subcategory>:InteriorEquipment:Electricity	Specific Subcategory	Electric Equipment, OTC Baseboard Heat
Gas:Facility	Entire Facility	Gas Equipment
Gas:Building	All Zones	Gas Equipment
Gas:Zone:<Zone Name>	Specific Zone	Gas Equipment
InteriorEquipment:Gas	AllZones	Gas Equipment
<End-Use Subcategory>:InteriorEquipment:Gas	Specific Subcategory	Gas Equipment

## 1.14 Group – Daylighting

Daylighting can be invoked in EnergyPlus by the use of two objects:**Daylighting:Controls** and **Daylighting:DELight:Controls**. These are described in the following object descriptions.

Note that Daylighting:Controls and Daylighting:DELight:Controls objects may be intermixed in a single IDF but may not be used in the same zone.

### 1.14.1 Daylighting:Controls

In this method daylighting illuminance levels are calculated and then used to determine how much the electric lighting can be reduced. The daylight illuminance level in a zone depends on many factors, including sky condition; sun position; calculation point; location, size, and glass transmittance of windows; window shading devices; and reflectance of interior surfaces. Reduction of electric lighting depends on daylight illuminance level, illuminance set point, fraction of zone controlled and type of lighting control.

#### 1.14.1.1 Field: Zone name

The name of the zone to which the following daylighting-related input applies.

#### 1.14.1.2 Field: Total Daylighting Reference Points

Allowed values are 1 or 2. This the number of reference points in the zone at which horizontal daylighting illuminance will be calculated based on input for the following fields. It is assumed that the photocells that control the overhead electric lighting respond to the light levels at the specified reference points.

#### 1.14.1.3 Fields: (X,Y,Z) of First Reference Point

Required if Total Daylighting Reference Points = 1 or 2. These three fields are the X, Y and Z values of the First Reference point in the coordinate system you specified for daylighting reference points in the GlobalGeometryRules object. Figure 53 shows an example using the relative coordinate (to zone) system. Z is typically at desk height (0.8 m).

If you want to divide a thermal zone into two independently-controlled lighting zones, then Total Daylighting Reference Points should be set to 2 and (X,Y,Z) of the Second Reference Point (see following input fields) should also be specified.

#### 1.14.1.4 Fields: (X,Y,Z) of Second Reference Point

The X, Y, and Z coordinates, in the same coordinate system, of the second daylighting reference point. Required if Total Daylighting Reference Points = 2. See Figure 53 for an example.

Figure 53. Example showing location of daylighting reference points in the zone coordinate system (relative) of a rectangular zone with three windows. (a) Perspective view, (b) plan view, (c) elevation view. All dimensions are in meters.

#### 1.14.1.5 Field: Fraction of Zone Controlled by First Reference Point

The fraction of the zone's floor-area whose electric lighting is controlled by the daylight illuminance at the First Reference Point. If there is only one reference point then a fraction equal to

$$1.0 - (\text{Fraction of Zone Controlled by First Reference Point})$$

is assumed to have no lighting control.

#### 1.14.1.6 Field: Fraction of Zone Controlled by Second Reference Point

The fraction of the zone's floor-area whose electric lighting is controlled by the daylight illuminance at the Second Reference Point. Required if Total Daylighting Reference Points = 2. A fraction equal to

$$1.0 - ([\text{Fraction of Zone Controlled by First Reference Point}] + [\text{Fraction of Zone Controlled by Second Reference Point}])$$

is assumed to have no lighting control.

#### 1.14.1.7 Field: Illuminance SetPoint at First Reference Point

The desired lighting level (in lux) at the First Reference Point. This is the lighting level that would be produced at this reference point at night if the overhead electric lighting were operating at full input power. Recommended values depend on type of activity; they may be found, for example, in the Lighting Handbook of the Illuminating Engineering Society of North America. A typical value for general office work (excluding computer terminals) is 500 lux.

#### 1.14.1.8 Field: Illuminance SetPoint at Second Reference Point

The desired lighting level (in lux) at the Second Reference Point. Required if Total Daylighting Reference Points = 2. This is the lighting level that would be produced at this reference point at night if the overhead electric lighting were operating at full input power.

#### 1.14.1.9 Field: Lighting Control Type

The type of overhead electric lighting control. All reference points specified are assumed to have this type of control.

For Lighting Control Type = 1 (continuous), the overhead lights dim continuously and linearly from (maximum electric power, maximum light output) to (minimum electric power, minimum light output) as the daylight illuminance increases. The lights stay on at the minimum point with further increase in the daylight illuminance.

For Lighting Control Type = 2 (stepped), the electric power input and light output vary in discrete, equally spaced steps. The number of steps is given by Number of Steps (Excluding Off) of Stepped Control. For example, if Number of Steps = 3 and Illuminance Setpoint = 600, then the following table shows the fraction of the lights that are on vs. daylight illuminance.

Table 18. Stepped Lighting Control Example

#### Example of a Stepped Lighting Control System with Three Steps

Daylight illuminance	Fraction of lights that are on
0-200	1.0
200-400	2/3
400-600	1/3
600 and above	0.0

Lighting Control Type = 3 (continuous/off) is the same as Lighting Control Type = 1 except that the lights switch off completely when the minimum dimming point is reached.

#### 1.14.1.10 Field: Glare Calculation Azimuth Angle of View Direction Clockwise from Zone y-Axis

Daylight glare from a window depends on occupant view direction. It is highest when you look directly at a window and decreases as you look away from a window. This field specifies the view direction for calculating glare. It is the angle, measured clockwise in the horizontal plane, between the zone y-axis and the occupant view direction.

#### 1.14.1.11 Field: Maximum Allowable Discomfort Glare Index

If a daylit zone has windows with shading devices (except exterior screens), the shades will be deployed if the daylight glare at the First Reference Point exceeds the value of this field. To get this type of glare control you have to specify Trigger = Glare, GlareOrSolarOnWindow, GlareOrHorizontalSolar, GlareOrOutsideAirTemp, GlareOrZoneAirTemp or GlareOrZoneLoad in WindowProperty:ShadingControl for one or more windows in the zone (see WindowProperty:ShadingControl).

If a zone has two or more windows with glare control, the shading devices will be deployed one by one in the order in which the windows are input until the glare level at each reference point falls below Maximum Allowable Discomfort Glare Index or is as close as possible to it.

The following table gives recommended values of Maximum Allowable Discomfort Glare Index.

Table 19. Recommended Values -- Discomfort Glare Index

Recommended Values of Maximum Allowable Discomfort Glare Index	
Activity or zone type	Maximum Allowable Discomfort Glare Index
Art Galleries	16
Factories	
Rough work	28
Engine assembly	26
Fine assembly	24
Instrument assembly	22
Hospital wards	18
Laboratories	22
Museums	20
Offices	22
School classrooms	20

#### 1.14.1.12 Field: Minimum Input Power Fraction for Continuous Dimming Control

For Lighting Control Type = 1 (continuous), the lowest power the lighting system can dim down to, expressed as a fraction of maximum input power (see figure, below). For Lighting Control Type = 3 (continuous/off) this is the power fraction reached just before the lights switch off completely.

Figure 54. Illustration of continuous dimming relationship

The figure above shows the relationship between electric light output and electrical input.

#### 1.14.1.13 Field: Minimum Light Output Fraction for Continuous Dimming Control

For Lighting Control Type = 1 (continuous), the lowest lighting output the lighting system can dim down to, expressed as a fraction of maximum light output (see

figure, above). This is the fractional light output that the system produces at minimum input power. For Lighting Control Type = 3 (continuous/off) this is the light output fraction reached just before the lights switch off completely.

#### 1.14.1.14 Field: Number of Stepped Control Steps

The number of steps, excluding off, in a stepped lighting control system (see figure, below). Required and must be >0 if Lighting Control Type = 2. The steps are assumed to be equally spaced.

Figure 55. Stepped lighting control with Number of Steps = 3.

#### 1.14.1.15 Field: Probability Lighting will be Reset When Needed in Manual Stepped Control

May be specified if a stepped lighting control system (Lighting Control Type = 2) is manually operated, such as in a simple, one-step (on-off) system. Gives the probability the occupants of a daylit zone will set the electric lights to the correct level to obtain the required illuminance. The rest of the time the lights are assumed to be set one step too high. For example, consider an on-off lighting system (Number of Steps = 1) with a set point of 600 lux and 0.7 reset probability. Then, when daylighting exceeds 600 lux, the electric lights will be off 70% of the time and on 30% of the time.

#### 1.14.1.16 Field: Availability Schedule Name

This alpha field is optional and may be used to define the name of a schedule that denotes whether or not the control is available to operate during a given time period. If the schedule value is greater than zero, then the controls will be available to operate for that time period. If the schedule value is zero or less, then the controls will not be available. If this field is left blank, the controls will be always available. For example, this can be useful for scheduling the daylighting controls off during design days so that the daylighting controls do not affect lighting power during sizing.

An IDF example:

```
Daylighting:Controls, ! Zone Name
1, ! Total Daylighting Reference Points
3.048,3.048,0.9, ! X,Y,Z coordinates of first reference point {m}
0.0,0.0,0.0, ! X,Y,Z coordinates of second reference point, if present {m}
0.99, ! Fraction of zone controlled by first reference point
0.0, ! Fraction of zone controlled by second reference point, if present
500., ! Illuminance setpoint at first reference point {lux}
500., ! Illuminance setpoint at second reference point, if present {lux}
1, ! Lighting control type {1=continuous,2=stepped,3=continuous/off}
180.0, ! Azimuth angle of view direction for glare calculation {deg},
! measured clockwise from zone y-axis. Value of 180 gives view
! (from reference point) that is directly at window, maximizing glare.
20.0, ! Maximum discomfort glare index for window shade control
0.3, ! Minimum input power fraction for continuous dimming control
0.2, ! Minimum light output fraction for continuous dimming control
0, ! Number of steps, excluding off, for stepped control
1.0; ! Probability electric lighting will be reset when needed (used only
! for stepped control, to simulate manual on/off control)
```

### 1.14.2 Guidelines for Daylighting Modeling (Detailed Method)

Following are some guidelines for preparing EnergyPlus input to model the effects of daylighting. Before studying these guidelines, however, you should read the description of each input field under Daylighting:Controls, and review the IDF example, above, and the sample daylighting input, PurchAirWithDaylighting.idf.

#### 1.14.2.1 Use of Window Multipliers

If an exterior wall in a daylit zone has a number of identical windows, the windows should be entered separately rather than using a window multiplier (ref: FenestrationSurface:Detailed). Using a multiplier would give an incorrect illuminance calculation since individual windows would not be positioned correctly on the wall.

#### 1.14.2.2 Use of Zone Multipliers

A zone multiplier should not be used on a daylit zone if the windows in the zone are shadowed by exterior obstructions like trees or neighboring buildings, or by obstructions caused by other parts of building. The reason for this is that the shadowing on the windows of the multiplied zone may be different from zone to zone depending on exactly how the shadows fall on the zones. However, a zone multiplier may be used on a daylit zone if the shadowing is by overhangs, fins and/or

window setback.

### 1.14.2.3 Thermal Zoning for Daylighting

To correctly calculate both direct and inter-reflected daylight illuminance you should try to model a thermal zone consisting of several similar rooms separated by interior walls as a representative room with a zone multiplier (ref: Zone). An example of this is shown in Figure 56. Room-1 is the representative room, with a zone multiplier = 4.

Interior walls IW-1, IW-2 and IW-3 should be treated as adiabatic, i.e., they should have Outside Boundary Condition = Surface and Outside Boundary Condition Object = IW-1, IW-2, or IW-3, respectively (ref: BuildingSurface:Detailed). Similarly, if the ceiling and floor of Room-1 are interior surfaces, they should be treated as adiabatic.

Figure 56. For daylighting purposes the thermal zone enclosed by the dashed boundary line should be modeled as a typical zone (Room-1) with a zone multiplier of 4.

Sometimes a representative room cannot be found. Figure 57 shows a section of a building with four rooms having different daylighting characteristics because of different floor area, orientation and/or window size. In this case lumping the rooms into a single thermal zone would give nonsensical daylighting illuminance values because of the presence of the interior walls, which EnergyPlus ignores when calculating illuminance reaching a reference point directly from a window (i.e., without reflection). The solution in this case is to describe each room as a separate thermal zone with its own daylighting reference points, and input the interior walls because these will participate in the calculation of inter-reflected illuminance.

Figure 57. Rooms A, B, C and D have different daylighting characteristics. If lumped into a single thermal zone the daylighting calculation will be less accurate because the blockage of direct light by the interior walls between these rooms is modeled with some simplifications (see Interior Obstructions below). To get a good daylighting calculation each room should be input as a separate thermal zone.

### 1.14.2.4 Multiple Lighting Zones

The detailed daylighting calculation allows a thermal zone to be divided into two independently-controlled lighting zones. (See the fields: Fraction of Zone Controlled by First Reference Point, Fraction of Zone Controlled by Second Reference Point, Illuminance SetPoint at First Reference Point, and Illuminance SetPoint at Second Reference Point.) An example is shown in Figure 58, where a relatively deep thermal zone has two lighting zones of equal area.

Figure 58. Two independently-controlled lighting zones, each with 50% of the area of the thermal zone.

### 1.14.2.5 Fins, Overhangs and Other Exterior Obstructions

The daylighting calculation accounts for the presence of exterior obstructions in determining the amount of light that strikes the windows. For daylighting purposes exterior obstructions fall into three categories:

- (1) Fins, overhangs, trees, neighboring buildings, etc., entered with the objects Shading:Zone:Detailed, Shading:Site:Detailed, or Shading:Building:Detailed.
- (2) Building surfaces like walls and roofs (in an L-shaped building, for example).

(3) Surfaces associated with window setback.

Category (1) obstructions can have an associated solar transmittance schedule (see description of the field Transmittance Schedule Name for these shading surfaces). If this schedule is not specified, the surface is opaque (has zero transmittance).

The daylighting calculation takes the transmittance into account in determining, for example, how much light enters a window through a translucent awning. It is assumed that the solar and visible transmittance is the same and that the surfaces are non-diffusing, i.e., they do not change the direction of transmitted light. Ref:Daylighting:Controls.

Category (2) and (3) surfaces are assumed to be opaque.

Surfaces in all three categories are assumed to be black, i.e., they do not reflect light, unless you set if “Reflections” option is chosen in the Building object. Then obstructions can reflect light, such as the top of an overhang reflecting light onto the window above. Ref: Building, Field: Solar Distribution (with reflections options).

### 1.14.2.6 Interior Obstructions

The daylighting calculation accounts for the presence of interior obstructions that lie between a window and a reference point. Unlike exterior obstructions, which can be light transmitting, interior obstructions are assumed to be opaque. Interior obstructions can reduce or eliminate the light directly reaching the reference point through a window.

However, interior obstructions that are walls, ceilings or floors are reflecting so they contribute to the inter-reflected component of daylight illuminance as do the non-obstructing zone surfaces.

Interior obstructions can belong to the Shading object series. This type of obstruction is assumed to be non-reflecting so does not contribute to the inter-reflected component of daylight illuminance.

An example of an interior obstruction that is a wall in an L-shaped room is shown in Figure 59. Here, wall A (or, equivalently, Wall B) prevents light from directly getting to the Reference Point from the window.

Figure 59. Wall A (or Wall B) is an interior obstruction that prevents light from directly reaching the daylighting reference point from the window.

### 1.14.2.7 Double Façades: Daylighting through Interior Windows

The Daylighting:Controls method, with no additional user input, calculates the contribution of daylight that passes into a target zone through interior windows<sup>11</sup>. The origin of this daylight is exterior windows in adjacent zones that share interior windows with the target zone. This capability is aimed at daylighting through a **double façade** (also called “double envelope” or “double skin.”)

This is illustrated in Figure 60, which shows a double-façade buffer zone, Z0, with exterior windows EW1 and EW2. Z0 shares interior windows IW1, IW2 and IW3 with daylit occupied zones ZD1, ZD2 and ZD3, respectively (“daylit” here means the zone has an associated Daylighting:Controls object). The daylight illuminance at reference points RP1, RP2 and RP3 comes from the interior windows and has two main sources:

1. Daylight that passes through both an exterior window and an interior window in Z0 and reaches a reference point without reflection. This is called “direct illuminance.”
2. Daylight from Z0 that passes through an interior window and reaches a reference point by inter-reflection in the daylit zone. Because the program calculates this source from the interior solar distribution in Z0 it is recommended that the most accurate calculation of this distribution be made, which occurs if Solar Distribution = FullInteriorAndExterior in the Building object.

A third possible source is neglected because it is generally small in double-façade cases. This is daylight that is reflected from the surfaces of Z0, passes through an interior window and then reaches a reference point without inter-reflection in the daylit zone.

PurchAirWithDoubleFacadeDaylighting.idf is an input example of daylighting through an interior window.

Figure 60. Vertical section through a double-façade building showing daylighting through interior windows. The dashed lines show that (1) reference point RP1 receives direct light from exterior window EW1 via interior window IW1; (2) RP2 receives direct light from EW1 and EW2 via IW2; and (3) RP3 receives direct light from EW2 via IW3.

#### 1.14.2.8 Interior Window Daylighting Configurations that EnergyPlus Can Calculate

Figure 61 shows schematically the general configuration of daylighting through interior windows that can be calculated with EnergyPlus. Here, daylit zone ZD has one or more interior windows that are adjacent to other zones, each of which has one or more exterior windows. ZD itself may or may not have exterior windows. If it does, then the daylight illuminance from its exterior and interior windows will be additive. The zones adjacent to ZD may or may not be daylit and may or may not have other interior windows that are not adjacent to ZD. (The program does not consider the illuminance in ZD from electric lighting in adjacent zones.)

Figure 61. General configuration of daylighting through interior windows that can be calculated with EnergyPlus. IW = interior window, EW = exterior window.

#### 1.14.2.9 Interior Window Daylighting Configurations that EnergyPlus Cannot Calculate

Figure 62 shows schematically a configuration of daylighting through interior windows that cannot be calculated with EnergyPlus. Here, zone Z has an interior window that is adjacent to zone Z1 which in turn has an interior window adjacent to zone Z2. However, the daylight from the exterior window in Z2 that enters Z after passing through Z1 is not calculated because Z2 is not adjacent to Z.

Figure 62. Configuration in which daylighting of zone Z through its interior window cannot be calculated with EnergyPlus. IW = interior window, EW = exterior window.

#### 1.14.2.10 Restrictions on Shading Devices

There are two restrictions on the use of exterior-window shading devices when a daylit zone has interior windows:

- 1) If two daylit zones share an interior window, neither zone can have an exterior window whose shading device does glare control (i.e., the WindowProperty:ShadingControl for the exterior window has Glare Control Is Active = Yes).
- 2) If two daylit zones share an interior window, neither zone can have an exterior window with a WindowProperty:ShadingControl that has Shading Control Type = MeetDaylightIlluminanceSetpoint.

### 1.14.3 DELight Daylighting Method

The DELight method of analyzing daylighting in buildings is very similar to that used in the Detailed method. For each point in time, DELight calculates the interior daylighting illuminance at specified reference points and then determines how much the electric lighting can be reduced while still achieving a combined daylighting and electric lighting illuminance target. The daylight illuminance level in a zone depends on many factors, including exterior light sources; location, size, and visible light transmittance of simple and complex fenestration systems; reflectance of interior surfaces; and location of calculation reference points. The subsequent reduction of electric lighting depends on daylight illuminance level, illuminance set point, fraction of zone controlled, and type of lighting control.

There are two primary differences between the Detailed and DELight methods of calculating interior illuminance levels. The first is that DELight includes the capability of analyzing complex fenestration systems that include geometrically complicated shading systems (e.g., roof monitors) and/or optically complicated glazings (e.g., prismatic or holographic glass). The second key difference is that DELight uses a radiosity method to calculate the effects of light reflection inside a zone. These methods are discussed in more detail in the engineering documentation.

There are other important differences between the two methods. One is the inability of DELight to perform the type of dynamic shading controls possible using the Detailed method at each point in time during the thermal simulation (e.g., changes in electrochromic glazing transmittances and blind slat angles). Another is the DELight ability to include more than two reference points in its interior illuminance and electric lighting reduction calculations. A third is the current lack of visual quality (e.g., glare) calculations performed by DELight. Fourth, the modeling of interior obstructions is different in the two methods. In the DELight method interior obstructions block interreflections but do not block the initial direct illuminance. In the Detailed method, interior obstructions block the initial direct illuminance but do not block interreflections. See the engineering documentation for more details.

Input for invoking the DELight method involves three object types: **Daylighting:DELight:Controls**, **Daylighting:DELight:ReferencePoint**, and **Daylighting:DELight:ComplexFenestration**. Each of these objects is described below.

#### 1.14.4 Daylighting:DELight:Controls

The first input object required for invoking the DELight method is the Daylighting:DELight:Controls object, which defines the parameters of each daylighting zone within a building. This object must be associated with a specific thermal zone within the building for which the reduction in electric lighting due to daylight illuminance will be accounted.

**1.14.4.1 Field: Name**

User name of the DELight daylighting zone to which the following input applies.

**1.14.4.2 Field: Zone Name**

The name of the thermal Zone hosting this DELight daylighting zone. This must be a valid name that has been associated with a thermal Zone contained in the same EnergyPlus input data file.

**1.14.4.3 Field: Lighting Control Type**

The type of overhead electric lighting control. All reference points specified are assumed to have this type of control.

For Lighting Control Type = 1 (continuous), the overhead lights dim continuously and linearly from (maximum electric power, maximum light output) to (minimum electric power, minimum light output) as the daylight illuminance increases. The lights stay on at the minimum point with further increase in the daylight illuminance.

For Lighting Control Type = 2 (stepped), the electric power input and light output vary in discrete, equally spaced steps. The number of steps is given by Number of Steps (Excluding Off) of Stepped Control. For example, if Number of Steps = 3 and Illuminance Setpoint = 600, then the following table shows the fraction of the lights that are on vs. daylight illuminance.

Table 20. Stepped Lighting Control Example

**Example of a Stepped Lighting Control System with Three Steps**

Daylight illuminance	Fraction of lights that are on
0-200	1.0
200-400	2/3
400-600	1/3
600 and above	0.0

Lighting Control Type = 3 (continuous/off) is the same as Lighting Control Type = 1 except that the lights switch off completely when the minimum dimming point is reached.

**1.14.4.4 Field: Minimum Input Power Fraction for Continuous Dimming Control**

For Lighting Control Type = 1 (continuous), the lowest power the lighting system can dim down to, expressed as a fraction of maximum input power (see figure, below). For Lighting Control Type = 3 (continuous/off) this is the power fraction reached just before the lights switch off completely.

Figure 63. Illustration of continuous dimming relationship

The figure above shows the relationship between electric light output and electrical input.

**1.14.4.5 Field: Minimum Light Output Fraction for Continuous Dimming Control**

For Lighting Control Type = 1 (continuous), the lowest lighting output the lighting system can dim down to, expressed as a fraction of maximum light output (see figure, above). This is the fractional light output that the system produces at minimum input power. For Lighting Control Type = 3 (continuous/off) this is the power fraction reached just before the lights switch off completely.

**1.14.4.6 Field: Number of Steps (Excluding Off) for Stepped Control**

The number of steps, excluding off, in a stepped lighting control system (see figure, below). Required and must be >0 if Lighting Control Type = 2. The steps are assumed to be equally spaced.

Figure 64. Stepped lighting control with Number of Steps = 3.

#### 1.14.4.7 Field: Probability Lighting Will Be Reset When Needed in Manual Stepped Control

May be specified if a stepped lighting control system (Lighting Control Type = 2) is manually operated, such as in a simple, one-step (on-off) system. Gives the probability the occupants of a daylit zone will set the electric lights to the correct level to obtain the required illuminance. The rest of the time the lights are assumed to be set one step too high. For example, consider an on-off lighting system (Number of Steps = 1) with a set point of 600 lux and 0.7 reset probability. Then, when daylighting exceeds 600 lux, the electric lights will be off 70% of the time and on 30% of the time.

#### 1.14.4.8 Field: Gridding Resolution

The maximum surface area for nodes in gridding (subdividing) all surfaces in the DELight zone. All reflective and transmitting surfaces will be subdivided into approximately square nodes that do not exceed this maximum. Higher resolution subdivisions require greater calculation times, but generally produce more accurate results. This same gridding resolution is also used to subdivide any Complex Fenestration System surfaces. It is advisable to perform at least one simulation of new input using a small gridding resolution such as 0.1m<sup>2</sup> to compare these results against simulation runs at lower resolution (i.e., higher maximum area nodal grids) to get a sense of possible levels of error.

An IDF example:

```
Daylighting:DELIGHT:Controls,
  DELIGHT NORTH ZONE, !- DELight Zone Name
  NORTH ZONE, !- Zone Name
  1, !- Lighting control type
  0.3, !- Minimum input power fraction for continuous dimming control
  0.2, !- Minimum light output fraction for continuous dimming control
  0, !- Number of steps (excluding off) for stepped control
  1.0, !- Probability lighting will be reset when needed in manual stepped control
  1.0; !- Gridding Resolution {m2}
```

### 1.14.5 Daylighting:DELIGHT:ReferencePoint

The second input object required for invoking the DELight method is the Daylighting:DELIGHT:ReferencePoint object, which defines the parameters of each Reference Point within the associated DELight daylighting zone. This object must be associated with a specific Daylighting:DELIGHT:Controls object instance. There may be up to a maximum of 100 Reference Points for each DELight daylighting zone. Each Reference Point that is input does NOT need to be included in the control of the electric lighting system within the zone. This is determined by the fraction of the zone controlled by each Reference Point, which can be input as 0. Note that the sum of all Reference Point control fractions must equal 1 to obtain correct overall results.

#### 1.14.5.1 Field: Name

User name of the DELight daylighting Reference Point to which the following input applies.

#### 1.14.5.2 Field: DELight Name

The name of the Daylighting:DELIGHT:Controls object instance hosting this Reference Point. This must be a valid name that has been associated with a DELight daylighting Zone contained in the same EnergyPlus input data file.

#### 1.14.5.3 Fields: (X,Y,Z) of Reference Point

These three fields are the X, Y and Z values of the Reference point in the coordinate system you specified for daylighting reference points in the GlobalGeometryRules object. Figure 65 shows an example using the relative coordinate (to zone) system. Z is typically at work surface height (e.g., 0.8m for a desk).

Figure 65. Example showing location of two daylighting reference points in the zone coordinate system (relative) of a rectangular zone with three windows. (a) Perspective view, (b) plan view, (c) elevation view. All dimensions are in meters.

#### 1.14.5.4 Field: Fraction of Zone Controlled by Reference Point

The zone floor-area fraction of the electric lighting that is controlled by the daylight illuminance at this Reference Point. If the sum of the values for this field for all Reference Points input for a given daylighting zone is less than 1.0, then the remaining fraction (i.e.,  $1.0 - \text{Sum}$ ) is assumed to not have lighting control.

Note that Reference Points may be input with a 0.0 value for this fraction. In this case, daylight factors and interior illuminance values will be calculated for the Reference Point, but it will play no role in controlling the electric lighting within the daylighting zone to which it belongs.

#### 1.14.5.5 Field: Illuminance Setpoint at Reference Point

The desired lighting level (in lux) at this Reference Point. This is assumed to be the lighting level that would be produced at this reference point at night if the overhead electric lighting were operating at full input power. Recommended values depend on the type of activity and may be found, for example, in the Lighting Handbook of the Illuminating Engineering Society of North America. A typical value for general office work (excluding computer terminals) is 500 lux.

An IDF example:

```
Daylighting:DELight:ReferencePoint,
  RefPt 2,           !- Reference Point Name
  DElight NORTH ZONE, !- DElight Zone Name
  5.0,              !- X-coordinate of reference point {m}
  3.0,              !- Y-coordinate of reference point {m}
  0.9,              !- Z-coordinate of reference point {m}
  0.5,              !- Fraction of zone controlled by reference point
  500.;            !- Illuminance setpoint at reference point {lux}
```

#### 1.14.6 Daylighting:DELight:ComplexFenestration

The third input object related to the DElight method is the Daylighting:DELight: Complex Fenestration object. The DElight daylighting analysis method can be applied to daylighting zones that contain only simple fenestration systems such as windows and skylights that are standard EnergyPlus sub-surfaces. In this situation, no Daylighting:DELight: Complex Fenestration object would be input.

In addition to analyzing simple fenestration systems, DElight includes the capability of analyzing complex fenestration systems such as geometrically complicated static shading systems (e.g., roof monitors) and/or optically complicated glazings (e.g., prismatic or holographic glass). This capability is based on characterizing these complex fenestration systems (CFS) using bi-directional transmittance distribution functions (BTDF). In general, BTDF data for a specific CFS must be either measured or simulated (e.g., using ray-tracing techniques) prior to employing DElight to analyze it within EnergyPlus. The current implementation of DElight CFS calculations within EnergyPlus supports two approaches to the input of BTDF, an analytical approach and a file-based approach. The details of inputting these two approaches are described below under the User Complex Fenestration Type field.

Two analytical CFS BTDF types are currently supported, window and light shelf. The file-based approach requires that a user has access to a data file containing raw BTDF data that DElight reads as additional input during its analysis calculations. BTDF data files are described separately since it is anticipated that individual EnergyPlus users will not create these data files themselves.

The methods related to characterizing and analyzing CFS using BTDF are still evolving. DElight is an early implementation of CFS analysis methods. These methods, and the input associated with them here, will likely change in the future.

##### 1.14.6.1 Field: User Name

User name of the DELight daylighting Complex Fenestration to which the following input applies.

#### 1.14.6.2 Field: Complex Fenestration Type

Type name of the DELight daylighting Complex Fenestration system to be analyzed. This type name must take one of the following two forms.

BTDF^GEN^Analytical Type^Normal Visible Transmittance^Dispersion Angle

BTDF^FILE^Filename

The first form above is for supported analytical CFS types which currently include WINDOW and LIGHTSHELF. While these analytical types are relatively simple, they represent flexible ways to explore diffusing CFS systems and the impact of light shelves in redirecting light through an aperture. Each of these types also requires the visible transmittance of the CFS at normal incidence angle, and a dispersion angle (in degrees) that represents the “spread” of transmitted light. A small dispersion angle of 10 corresponds to clear glazing while a large angle of 90 corresponds to perfectly diffusing glazing. The “^” symbol must be used as a delimiter between sub-fields within this Complex Fenestration type name string as shown in the IDF example for WINDOW below, and in the DELight sample input data files.

The second form above is for CFS types for which there is pre-measured or pre-simulated BTDF data. In this case the Filename sub-field must be a valid data file name that is associated with an existing BTDF dataset that DELight can use in its calculations.

#### 1.14.6.3 Field: Building Surface Name

The name of the heat transfer surface object instance hosting this Complex Fenestration, analogous to the Building Surface Name field for subsurfaces such as Windows. This must be a valid name that has been associated with a heat transfer surface contained in the same EnergyPlus input data file.

#### 1.14.6.4 Field: Window Name

The name of the Window (ref: FenestrationSurface:Detailed object) instance that will be used to account for the geometry, and the solar/thermal gains/losses, of the Complex Fenestration system surface. This must be a valid name that has been associated with a Window contained in the same EnergyPlus input data file. The geometry for the Complex Fenestration is taken from the geometry input for this standard EnergyPlus subsurface, hence the term “Doppelganger.”

Note that DELight only deals with the visible spectrum of light transmitted through a Complex Fenestration. To account for the solar/thermal influences of a Complex Fenestration, a geometrically coincident subsurface that will be accounted for by methods already within EnergyPlus must be defined in the input data file. This is an interim solution to the issue of accounting for solar/thermal influences that will likely change as techniques analogous to the daylighting analysis of BTDF are developed.

#### 1.14.6.5 Field: Fenestration Rotation

The in-plane counter-clockwise rotation angle between the Complex Fenestration optical reference direction and the base edge of the Doppelganger Surface geometry. The Complex Fenestration optical reference direction is the direction of the zero azimuth angle for the BTDF dataset. This Rotation angle will typically be zero when the Doppelganger surface is rectangular and its width edge is aligned with the Complex Fenestration optical reference direction.

An IDF example for an analytical WINDOW type CFS:

```
Daylighting:DELight:ComplexFenestration,  
Window CFS,          !- DELight Complex Fenestration User Name  
BTDF^GEN^WINDOW^1.0^20.0,    !- Complex Fenestration Type  
Zn003:WALL001,    !- Complex Fenestration Host Surface  
Zn003:Wall001:Doppel001, !- Doppelganger Surface Name  
0.0;                !- Fenestration Rotation {deg}
```

### 1.14.7 DELight Output

In addition to the daylighting-specific outputs for DELight listed below, two ASCII text files are created during an EnergyPlus run that includes DELight analysis. Following completion of an EnergyPlus run, these files are given names that consist of the project name appended with DELight.in and DELight.out. The format of these files is described in the Output Details and Examples document.

Zone,Average,Daylighting Reference Point Illuminance [lux]

Zone,Average,Daylighting Lighting Power Multiplier []

#### 1.14.7.1 Daylighting Reference Point Illuminance [lux]

The total daylight illuminance at a DELight reference point from all of the exterior windows in a daylit zone.

#### 1.14.7.2 Daylighting Lighting Power Multiplier []

The amount by which the overhead electric lighting power in a zone is multiplied due to usage of DELight calculated daylighting to dim or switch electric lights. For example, if the multiplier is M and the electric power without dimming is P, then the electric power with dimming is M\*P. The multiplier varies from 0.0, which corresponds to maximum dimming (zero electric lighting), to 1.0, which corresponds to no dimming.

## 1.14.8 Daylighting Output

The following daylighting-specific outputs are available for Daylighting:Controls:

- Zone,Average,Site Exterior Beam Normal Illuminance [lux]
- Zone,Average,Site Exterior Horizontal Beam Illuminance [lux]
- Zone,Average,Site Exterior Horizontal Sky Illuminance [lux]
- Zone,Average,Site Beam Solar Radiation Luminous Efficacy [lum/W]
- Zone,Average,Site Sky Diffuse Solar Radiation Luminous Efficacy [lum/W]
- Zone,Average,Site Daylighting Model Sky Clearness []
- Zone,Average,Site Daylighting Model Sky Brightness []
- Surface,Average,Daylighting Window Reference Point 1 View Luminance [cd/m2]
- Surface,Average,Daylighting Window Reference Point 1 Illuminance [lux]
- Zone,Average,Daylighting Reference Point 1 Illuminance [lux]
- Zone,Average,Daylighting Reference Point 1 Glare Index []
- Zone,Sum,Daylighting Reference Point 1 Glare Index Setpoint Exceeded Time [hr]
- Zone,Sum,Daylighting Reference Point 1 Daylight Illuminance Setpoint Exceeded Time [hr]
- Surface,Average,Daylighting Window Reference Point 2 View Luminance [cd/m2]
- Surface,Average,Daylighting Window Reference Point 2 Illuminance [lux]
- Zone,Average,Daylighting Reference Point 2 Illuminance [lux], if applicable
- Zone,Average,Daylighting Reference Point 2 Glare Index [], if applicable
- Zone,Sum,Daylighting Reference Point 2 Glare Index Setpoint Exceeded Time [hr]
- Zone,Sum,Daylighting Reference Point 2 Daylight Illuminance Setpoint Exceeded Time [hr]
- Zone,Average,Daylighting Lighting Power Multiplier []

### 1.14.8.1 Site Exterior Beam Normal Illuminance [lux]

Beam normal illuminance of the sun at the earth's surface, measured in lux (lumens/m<sup>2</sup>)

### 1.14.8.2 Site Exterior Horizontal Beam Illuminance [lux]

Beam illuminance on an unobstructed horizontal plane at the earth's surface. Equals "Site Exterior Beam Normal Illuminance" times sine of solar altitude.

### 1.14.8.3 Site Exterior Horizontal Sky Illuminance [lux]

Illuminance from sky solar radiation on an unobstructed horizontal plane at the earth's surface. The total exterior horizontal illuminance is the sum of "Site Exterior Horizontal Beam Illuminance" and "Site Exterior Horizontal Sky Illuminance."

### 1.14.8.4 Site Beam Solar Radiation Luminous Efficacy [lum/W]

A measure of the visible light content of beam solar radiation; equal to the number of lumens per watt of beam solar radiation. Depends on atmospheric conditions (moisture, turbidity, cloudiness) and solar altitude.

### 1.14.8.5 Site Sky Diffuse Solar Radiation Luminous Efficacy [lum/W]

A measure of the visible light content of sky diffuse solar radiation; equal to the number of lumens per watt of sky diffuse solar radiation. Depends on atmospheric conditions (moisture, turbidity, cloudiness) and solar altitude.

### 1.14.8.6 Site Daylighting Model Sky Clearness [ ]

Clearness of sky. One of the factors used to determine sky type and luminous efficacy of solar radiation (see *EnergyPlus Engineering Document*). Sky Clearness close to 1.0 corresponds to an overcast sky. Sky Clearness > 6 is a clear sky.

#### 1.14.8.7 Site Daylighting Model Sky Brightness [ ]

Brightness of sky. One of the factors used to determine sky type and luminous efficacy of solar radiation (see *EnergyPlus Engineering Document*).

#### 1.14.8.8 Daylighting Window Reference Point 1 View Luminance [cd/m2]

The area-averaged luminance of an exterior window as viewed from the first reference point in the daylit zone containing the window. In general, higher window luminance values are associated with higher daylight glare values. (Printed only for exterior windows in daylit zones without interior windows.)

#### 1.14.8.9 Daylighting Window Reference Point 1 Illuminance [lux]

The contribution from a particular exterior window to the daylight illuminance at the first reference point in the daylit zone containing the window. (Not printed for exterior windows in daylit zones with interior windows.)

#### 1.14.8.10 Daylighting Reference Point 1 Illuminance [lux]

The total daylight illuminance at the first reference point from all of the windows in a daylit zone.

#### 1.14.8.11 Daylighting Reference Point 1 Glare Index [ ]

The daylight glare index at the first reference point in a daylit zone.

#### 1.14.8.12 Daylighting Reference Point 1 Glare Index Setpoint Exceeded Time [hr]

The number of hours when the calculated daylight glare index at the first reference point exceeds the glare index setpoint.

#### 1.14.8.13 Daylighting Reference Point 1 Daylight Illuminance Setpoint Exceeded Time [hr]

The number of hours when the calculated daylight illuminance at the first reference point exceeds the daylight illuminance setpoint.

#### 1.14.8.14 Daylighting Reference Point 2 Illuminance [lux]

The total daylight illuminance at the second reference point from all of the windows in a daylit zone.

#### 1.14.8.15 Daylighting Window Reference Point 2 View Luminance [cd/m2]

The area-averaged luminance of an exterior window as viewed from the second reference point, if present, in the daylit zone containing the window. Note that, for a bare window, this value can be different from the corresponding value at the first reference point since different regions of the sky and ground will be visible from the two reference points, and different ranges of angles of incidence and associated glass transmittance values will be involved. (Not printed for exterior windows in daylit zones with interior windows.)

#### 1.14.8.16 Daylighting Window Reference Point 2 Illuminance [lux]

The contribution from a particular exterior window to the daylight illuminance at the second reference point, if present, in the daylit zone containing the window. (Not printed for exterior windows in daylit zones with interior windows.)

#### 1.14.8.17 Daylighting Reference Point 2 Glare Index [ ]

The daylight glare index at the second reference point, if present, in a daylit zone.

#### 1.14.8.18 Daylighting Reference Point 2 Glare Index Setpoint Exceeded Time [hr]

The number of hours when the calculated daylight glare index at the second reference point exceeds the glare index setpoint.

#### 1.14.8.19 Daylighting Reference Point 2 Daylight Illuminance Setpoint Exceeded Time [hr]

The number of hours when the calculated daylight illuminance at the second reference point exceeds the daylight illuminance setpoint.

#### 1.14.8.20 Daylighting Lighting Power Multiplier [ ]

The amount by which the overhead electric lighting power in a zone is multiplied due to usage of daylighting to dim or switch electric lights. For example, if the multiplier is  $M$  and the electric power without dimming is  $P$ , then the electric power with dimming is  $M \cdot P$ . The multiplier varies from 0.0, which corresponds to maximum dimming (zero electric lighting), to 1.0, which corresponds to no dimming.

### 1.14.9 Output: IlluminanceMap

The Output:IlluminanceMap object expands on the reporting capabilities of the daylighting simulation. For any zone simulated with Daylighting:Controls, the illuminance map can generate up to 2,500 points of additional daylighting illuminance values. The resulting map is output as a comma delimited text file that can

be imported into a spreadsheet program for rapid visualization of the daylighting illuminance patterns in a zone. The values are produced on an hourly basis. The Z height of the map is constant (parallel to a flat floor). More than one illuminance map can be created for a zone.

#### 1.14.9.1 Field: Name

The name of the map object.

#### 1.14.9.2 Field: Zone Name

Reference to a zone with Daylighting:Controls.

#### 1.14.9.3 Field: Z Height

The height or elevation of the grid of daylighting points.

#### 1.14.9.4 Field: X Minimum Coordinate

The minimum X coordinate boundary for the map.

#### 1.14.9.5 Field: X Maximum Coordinate

The maximum X coordinate boundary for the map.

#### 1.14.9.6 Field: Number of X Grid Points

The number of daylighting reference points in the X direction from the minimum to the maximum boundaries. The maximum number of points that can be generated is 2500 (Number of X Grid Points X Number of Y Grid Points).

#### 1.14.9.7 Field: Y Minimum Coordinate

The minimum Y coordinate boundary for the map.

#### 1.14.9.8 Field: Y Maximum Coordinate

The maximum Y coordinate boundary for the map.

#### 1.14.9.9 Field: Number of Y Grid Points

The number of daylighting reference points in the Y direction from the minimum to the maximum boundaries. The maximum number of points that can be generated is 2500 (Number of X Grid Points X Number of Y Grid Points).

Note: Daylighting factors cannot be accurately calculated for reference points that are very close to a wall or window (less than 0.15 m or 6 inches). An error is reported for a reference point that is too close to a window, but no error is reported for a point that is too close to a wall.

```
Output: IlluminanceMap,  
  Daylit Map,      ! Map Name  
  Daylit Zone,    ! Zone Name  
  0,              ! Z Height [m]  
  0.1,            ! X Minimum Coordinate [m]  
  4.9,            ! X Maximum Coordinate [m]  
  10,             ! Number of X Grid Points  
  0.1,            ! Y Minimum Coordinate [m]  
  9.9,            ! Y Maximum Coordinate [m]  
  10;             ! Number of Y grid Points
```

Since not all zones are rectangular, it is possible to have map points that are outside the zone. Any illuminance registered at these points is inaccurate and, additionally, a "\*" marks these values for easy observance.

### 1.14.10 OutputControl:IlluminanceMap:Style

This object specifies the "style" for the illuminance map output (described in the Output Details and Examples document). As described early in the document (see: EnergyPlus Output Processing), the user may select the "style" for the daylighting illuminance map output file (eplusmap.<ext>).

#### 1.14.10.1 Field: Column Separator

For this field, the desired separator for columns is entered. "Comma" creates comma separated fields/columns in the outputs (eplusmap.csv file is created). "Tab" creates tab separated fields/columns in the outputs (eplusmap.tab file is created). "Fixed" creates space separated fields/columns in the outputs (eplusmap.txt file is created) but these are not necessarily lined up for easy printing.

Note that both tab and comma separated files easily import into Excel™ or other spreadsheet programs. The tab delimited files can also be viewed by text

editors, word processing programs and easily converted to "tables" within those programs.

### 1.14.11 Daylighting Devices

Daylighting devices work in conjunction with the Daylighting:Controls object to simulate components that can improve daylighting in a zone.

Daylighting devices are also tightly integrated into the zone heat balance. The thermal effects of these devices are simulated with or without the use of a Daylighting:Controls object.

There are two types of daylighting device in EnergyPlus: tubular daylighting devices and daylighting shelves.

### 1.14.12 DaylightingDevice:Tubular

Tubular daylighting devices (TDDs), also known as tubular skylights or light pipes, are used to bring natural exterior daylight into the hard-to-reach, interior spaces of a building.

TDDs consist of three components: a dome, a pipe, and a diffuser.

Figure 66. Tubular daylighting device diagram.

In EnergyPlus each of these components corresponds to an object in the input file.

The dome and diffuser are defined in the same way as windows using the FenestrationSurface:Detailed object. The *Surface Type* field must be specified as TubularDaylightDome or TubularDaylightDiffuser accordingly.

The location and orientation of the dome surface affect the total amount of daylight collected.

The *Base Surface* of the diffuser object determines to which zone the daylighting is delivered. The location and orientation of the diffuser surface affect the amount of daylight received at the Daylighting:Controls reference points.

Although the object definition is the same as for a window, there are several restrictions on TubularDaylightDome and TubularDaylightDiffuser objects:

- Shading control devices are not allowed.
- Frames and dividers are not allowed.
- Multipliers must be 1.0.
- Dome, diffuser, and pipe areas (as given by diameter) must be approximately equal.
- Outside face environment objects are not allowed.
- Dome and diffuser constructions cannot be more than one layer.

Since commercial TDDs are assumed to be cylindrical in shape, it is recommended that the circular areas of the actual dome and diffuser be approximated with a square of equivalent area for the TubularDaylightDome and TubularDaylightDiffuser objects. Although it is possible to use a triangular surface instead, a square is a much better geometric approximation of a circle.

Note that the TubularDaylightDome surface is allowed to have a different position and tilt from the roof base surface. If the actual TDD projects some height above the roof surface, the TubularDaylightDome coordinates should be located accordingly.

Figure 67. Tubular daylighting device DXF output.

The TubularDaylightDome surface automatically casts a shadow on the roof base surface. However, since the pipe is not represented by a surface, it will not cast a shadow. If this effect must be simulated, one or more SURFACE:SHADING objects can be used.

The dome and diffuser objects are connected by the DAYLIGHTING DEVICE:TUBULAR object:

**1.14.12.1 Field: Name**

The name of the TDD object.

**1.14.12.2 Field: Dome Name**

Reference to a FenestrationSurface:Detailed object with *Surface Type* TubularDaylightDome.

**1.14.12.3 Field: Diffuser Name**

Reference to a FenestrationSurface:Detailed object with *Surface Type* TubularDaylightDiffuser.

**1.14.12.4 Field: Construction Name**

The construction of the TDD pipe. The visible and solar absorptance of the inside material layer determines the reflectivity of the inner mirrored surface of the TDD. This is very important for the overall transmittance of the TDD.

**1.14.12.5 Field: Diameter**

The diameter [m] of the TDD pipe. The area of the pipe must match the areas of the dome and diffuser.

**1.14.12.6 Field: Total Length**

The total length [m] of the TDD pipe between the dome and the diffuser, including the exterior part above the roof. The exterior length is determined internally by subtracting the transition zone lengths from the total length.

**1.14.12.7 Field: Effective Thermal Resistance**

The effective thermal resistance [ $m^2 \cdot K/W$ ], i.e. R-value, of the TDD between the exterior dome surface and the interior diffuser surface.

**1.14.12.8 Field: Transition Zone<#> Name**

Name of zone that the TDD pipe passes through before reaching the delivery zone.

**1.14.12.9 Field: Transition Zone <#> Length**

Length of pipe [m] in the transition zone. This is used for determining heat gains due to solar absorbed by the pipe in each transition zone. The distribution of absorbed solar gains can be customized by adjusting the length of pipe in each transition zone. The transition zone gain is proportional to the length of pipe in the zone. If no transition zones are specified, all solar absorbed by the pipe is lost to the exterior environment.

The *Transition Zone Name* and *Transition Zone Length* fields can be repeated for additional transition zones.

### 1.14.13 Tubular Daylighting Device Output

- Zone,Average,Tubular Daylighting Device Transmitted Solar Radiation Rate [W]
- Zone,Average,Tubular Daylighting Device Pipe Absorbed Solar Radiation Rate [W]
- Zone,Average,Tubular Daylighting Device Heat Gain Rate [W]
- Zone,Average,Tubular Daylighting Device Heat Loss Rate [W]
- Zone,Average,Tubular Daylighting Device Beam Solar Transmittance []
- Zone,Average,Tubular Daylighting Device Beam Visible Transmittance []
- Zone,Average,Tubular Daylighting Device Diffuse Solar Transmittance []
- Zone,Average,Tubular Daylighting Device Diffuse Visible Transmittance []

#### 1.14.13.1 Tubular Daylighting Device Beam Solar Transmittance []

This is the transmittance of beam solar radiation through the TDD.

#### 1.14.13.2 Tubular Daylighting Device Beam Visible Transmittance []

This is the transmittance of beam visible radiation, or daylight, through the TDD.

#### 1.14.13.3 Tubular Daylighting Device Diffuse Solar Transmittance []

This is the transmittance of diffuse solar radiation through the TDD.

#### 1.14.13.4 Tubular Daylighting Device Diffuse Visible Transmittance []

This is the transmittance of diffuse visible radiation, or daylight, through the TDD.

#### 1.14.13.5 Tubular Daylighting Device Heat Gain Rate [W]

This is the rate of heat gain to the zone by the TDD, in Watts.

#### 1.14.13.6 Tubular Daylighting Device Heat Loss Rate [W]

This is the rate of heat loss from the zone by the TDD, in Watts.

#### 1.14.13.7 Tubular Daylighting Device Pipe Absorbed Solar Radiation Rate [W]

This is the rate at which solar radiation is absorbed by the pipe in the TDD, in Watts.

#### 1.14.13.8 Tubular Daylighting Device Transmitted Solar Radiation Rate [W]

This is the rate at which solar radiation is transmitted by the TDD, in Watts.

In addition, several surface and window variables are also reported for the TubularDaylightDome and TubularDaylightDiffuser objects. For the TubularDaylightDome:

- Zone,Average,Surface Outside Face Sunlit Area [m2]
- Zone,Average,Surface Outside Face Sunlit Fraction []
- Zone,Average,Surface Outside Face Incident Solar Radiation Rate per Area[W/m2]
- Zone,Average,Surface Outside Face Incident Beam Solar Radiation Rate per Area[W/m2]
- Zone,Average,Surface Outside Face Incident Sky Diffuse Solar Radiation Rate per Area[W/m2]
- Zone,Average,Surface Outside Face Incident Ground Diffuse Solar Radiation Rate per Area[W/m2]
- Zone,Average,Surface Outside Face Beam Solar Incident Angle Cosine Value[]
- Zone,Average,Surface Window Transmitted Solar Radiation Rate [W]
- Zone,Average,Surface Window Total Glazing Layers Absorbed Solar Radiation Rate [W]

For the TubularDaylightDiffuser:

- Zone,Average,Surface Outside Face Incident Solar Radiation Rate per Area[W/m2](*incident inside of pipe*)
- Zone,Average,Surface Window Transmitted Solar Radiation Rate [W](*same as Tubular Daylighting Device Transmitted Solar Radiation Rate*)
- Zone,Average,Surface Window Total Glazing Layers Absorbed Solar Radiation Rate [W]

#### 1.14.14 DaylightingDevice:Shelf

Daylighting shelves, or simply light shelves, are another device for bringing more daylight into a building. Installed as an accessory to a window, daylighting shelves work by reflecting exterior light onto the ceiling of a room. Daylighting shelves can have an inside shelf, an outside shelf, or both.

Figure 68. Daylighting shelf diagram.

The inside shelf redistributes light that would have entered the zone anyway. Instead of entering as a beam, all light is reflected onto the zone ceiling and is converted to diffuse shortwave radiation.

The outside shelf changes the amount of light entering the zone. If the shelf surface is more reflective than the ground, it can increase the amount of light incident on the upper part of the window. However, the shading effect of the outside shelf on the lower part of the window must also be considered as it can easily negate any gain achieved in the upper part of the window. All light reflected from the outside shelf that enters the upper window is assumed to strike the ceiling.

Figure 69. Daylighting shelf DXF output.

In EnergyPlus a daylighting shelf is simulated using a DaylightingDevice:Shelf object in combination with up to three other objects: a window, a heat transfer surface, and an attached shading surface.

The window must be divided into two window surfaces: an upper window and a lower window. The upper window interacts directly with the daylighting shelf object and is not allowed to have any shading control devices or frames or dividers. The lower window does not interact with the daylighting shelf object, but does receive shading from the outside shelf. There are no restrictions on the lower window.

The inside shelf is defined as a regular heat transfer surface in the zone. However, the surface must have the *Outside Boundary Condition* field set to Surface with itself as the other zone surface. Shading and thermal mass effects are taken into account.

The outside shelf is defined as a Shading:Zone:Detailed object. The visible and solar absorptance of the outside material layer determines the reflectivity of the shelf.

NOTE: Unlike a regular Shading:Zone:Detailed object, the vertices of the outside shelf surface must be ordered so that the outward normal vector points *upward*, i.e. toward the upper window. This is necessary in order for the outside shelf to properly receive sunlight and shading from other surfaces. A mirror shading surface with the outward normal vector pointing in the opposite direction is automatically created by the program to shade the lower window.

The inside shelf and outside shelf are both optional. However, if neither shelf is specified, the daylighting shelf object has no effect on the simulation.

#### 1.14.14.1 Field: Name

The name of the daylighting shelf object.

#### 1.14.14.2 Field: Window Name

Reference to a FenestrationSurface:Detailed object with *Surface Type* WINDOW.

#### 1.14.14.3 Field: Inside Shelf Name

Reference to a BuildingSurface:Detailed object. This field is optional. If used, this surface must have OTHERZONESURFACE specified for the *Outside Face Environment* field and the referenced other zone surface must be itself. The number of vertices of this surface object must be 4.

#### 1.14.14.4 Field: Outside Shelf Name

Reference to a Shading:Zone:Detailed object. This field is optional. If used, the number of vertices of this surface object must be 4.

#### 1.14.14.5 Field: Outside Shelf Construction Name

Reference to a CONSTRUCTION object. This field is required if an outside shelf is specified. The visible and solar absorptance of the outside material layer determines the shelf reflectivity.

#### 1.14.14.6 Field: View Factor To Outside Shelf

User defined value for the view factor from the window to the outside shelf. This field is optional. If not specified, an exact view factor is calculated for two perpendicular rectangles of the same width having a shared edge. If the given surfaces do not meet these geometric requirements, it is necessary to specify a value here.

NOTE: It is up to the user to adjust the view factor to ground of the upper window to account for the part of the view blocked by the outside shelf. The calculated *View Factor To Outside Shelf* is reported in the eio file for this purpose. For the typical case where the shelf is parallel to the ground and the upper window is perpendicular to the ground, the view factor to ground is simply:  $0.5 - \text{View Factor To Outside Shelf}$ .

```

### 1.14.15 Shelf Daylighting Device Output

The view factor to outside shelf calculation shows up in the .eio file along with the associated window and window view factors to sky and ground:

```
! <Shelf Details>,Name,View Factor to Outside Shelf,Window Name,Window View Factor to Sky,Window View Factor to Ground
SHELF,0.29,DAYLIT UPPER WINDOW,0.50,0.21
```

This variable reports the calculated *View Factor To Outside Shelf* so that the user can correctly adjust the view factor to ground of the upper window.

The usual window and surface variables are relevant for the upper window:

- Zone,Average,Surface Outside Face Sunlit Area [m2]
- Zone,Average,Surface Outside Face Sunlit Fraction []
- Zone,Average,Surface Outside Face Incident Solar Radiation Rate per Area[W/m2]
- Zone,Average,Surface Outside Face Incident Beam Solar Radiation Rate per Area[W/m2]
- Zone,Average,Surface Outside Face Incident Sky Diffuse Solar Radiation Rate per Area[W/m2]
- Zone,Average,Surface Outside Face Incident Ground Diffuse Solar Radiation Rate per Area[W/m2]
- Zone,Average,Surface Outside Face Beam Solar Incident Angle Cosine Value[]
- Zone,Average,Surface Window Transmitted Solar Radiation Rate [W]
- Zone,Average,Surface Window Total Glazing Layers Absorbed Solar Radiation Rate [W]

- Zone,Average,Surface Window Heat Gain Rate [W]
- Zone,Average,Surface Window Heat Loss Rate [W]

The following surface variables are reported for the outside shelf surface, if specified:

- Zone,Average,Surface Outside Face Sunlit Area [m2]
- Zone,Average,Surface Outside Face Sunlit Fraction []
- Zone,Average,Surface Outside Face Incident Solar Radiation Rate per Area[W/m2]
- Zone,Average,Surface Outside Face Incident Beam Solar Radiation Rate per Area[W/m2]
- Zone,Average,Surface Outside Face Incident Sky Diffuse Solar Radiation Rate per Area[W/m2]
- Zone,Average,Surface Outside Face Incident Ground Diffuse Solar Radiation Rate per Area[W/m2]
- Zone,Average,Surface Outside Face Beam Solar Incident Angle Cosine Value[]

### 1.14.16 DaylightingDevice:LightWell

This object is used to model the impacts on daylighting of a “light well” that might be associated with exterior windows such as skylights. The light well model attenuates the light transmitted by the skylight. The attenuation is characterized by the **well efficiency**, which is the ratio of the amount of light leaving the well to the amount of light entering the well. The well efficiency varies from close to 1.0 to close to zero if there is high attenuation. The well efficiency is used only in the EnergyPlus detailed daylighting calculation, where it multiplies the beam and diffuse light transmitted by the skylight. (The well efficiency is not used in calculating the solar gain through the skylight.)

The input object describes the light well using basic characteristics of the geometry along with the visible reflectance of the well's side walls. The following figure diagrams how the geometry is characterized.

Figure 70. Skylight with light well: (a) perspective view, (b) vertical section.

If the bottom of the light well is a rectangle of side lengths  $c$  and  $d$ , as shown in (a), then the perimeter of the bottom of the well =  $2(c+d)$  and the area =  $cd$  (see description of field names for the Light Well object).

#### 1.14.16.1 Field: Exterior Window Name

The name of the exterior window that this Light Well is associated with. Generally this is a skylight in a roof. However, light wells can be applied to an exterior window of any slope. Light wells can be assigned to both rectangular and triangular exterior windows, but they should not be assigned to interior windows. Note that the sides of the light well can be sloped and the bottom of the light well can be any shape, not just rectangular.

#### 1.14.16.2 Field: Height of Well

The distance from the bottom of the skylight to the bottom of the well. If the skylight and well bottom are not coplanar, this is the distance from the center of the bottom of the skylight to center of the bottom of the well. See Figure 70.

#### 1.14.16.3 Field: Perimeter of Bottom of Well

The perimeter of the bottom opening of the well. See Figure 70.

#### 1.14.16.4 Field: Area of Bottom of Well

The area of the bottom opening of the well. A warning will be issued if this area is less than the area of the skylight, including frame if present. See Figure 70.

#### 1.14.16.5 Field: Visible Reflectance of Well Walls

The visible reflectance of the side walls of the well. If the walls do not all have the same reflectance, an area-weighted average value can be used. This is the well-wall reflectance expressed as a fraction.

An IDF example:

```
DaylightingDevice:LightWell, ! The well is 60% reflecting, is 1.2m high and has a 2.5m x 5.5m bottom opening.
```

```

Skylight-1, !- Name of Exterior Window that this Light Well Applies To
1.2,        !- Height of Well(m)
16.0,      !- Perimeter of Bottom of Well (m)
13.75,     !- Area of Bottom of Well (m2)
0.60;      !- Visible Reflectance of Well Walls

```

### 1.14.17 Daylighting Modeling Options

The following table shows what input objects/fields to use to model different daylighting options. It also gives the name of an example input, if available, that demonstrates the option.

Table 21. Daylighting Modeling Options

Option	Object/Field or Output Variable	Input File
Allow a thermal zone to be daylight	Daylighting:Controls, Daylighting:DELIGHT:Controls	PurchAirWithDaylighting.idf, DELIGHT-Detailed-Comparison.idf
Specify visible transmittance of the glazing	WindowMaterial:Glazing	PurchAirWithDaylighting.idf
Specify the visible transmittance of a shading device	WindowMaterial:Shade, WindowMaterial:Screen or WindowMaterial:Blind	PurchAirWindowBlind.idf
Use a shading device to control glare	WindowMaterial:Shade or WindowMaterial:Blind; WindowProperty:ShadingControl*	PurchAirWindowBlind.idf
Use electrochromic glazing to control glare	WindowProperty:ShadingControl/Shading Type = SwitchableGlazing, Shading Control Type = On If High Glare, Glare Control Is Active = Yes*	PurchAirWithDaylighting.idf
Adjust electrochromic glazing to just meet daylighting illuminance setpoint	WindowProperty:ShadingControl/Shading Type = SwitchableGlazing, Shading Control Type = MeetDaylightIlluminanceSetpoint*	
Print an illuminance map	Daylighting:Illuminance Map*	
Control electric lighting response to daylight illuminance level	Daylighting:Controls/Lighting Control Type = Continuous, Stepped or Continuous/Off, plus other fields; or .... Daylighting:DELIGHT:Controls/Lighting Control Type = Continuous, Stepped or Continuous/Off, plus other fields	PurchAirWithDaylighting.idf; DELIGHT-Detailed-Comparison.idf
Add a light shelf (with Daylighting:Controls)	DaylightingDevice:Shelf *	DaylightingDeviceShelf.idf
Add a light shelf (with Daylighting:DELIGHT:Controls)	Daylighting:DELIGHT:Controls	DELIGHTCFSLightShelf.idf
Add a light pipe	DaylightingDevice:Tubular *	DaylightingDeviceTubular.idf
Model a skylight having a light well	DaylightingDevice:LightWell *	
Model daylighting through double facade	See "Double Facades: Daylighting through Interior Windows"	PurchAirWithDoubleFacadeDaylighting.idf
Add diffusing (translucent) glass	WindowMaterial:Glazing/Solar Diffusing = Yes*	
Model complex fenestration	Daylighting:DELIGHT:Controls	DELIGHTCFSWindow.idf
Get a radiosity-based interior light inter-reflection calculation	Daylighting:DELIGHT:Controls	DELIGHT-Detailed-Comparison.idf
Find effect on daylighting of solar reflected from overhangs, neighboring buildings, etc.	Building/SolarDistribution uses "withReflections" option	
Find visible transmittance effect of dirt on window	WindowMaterial:Glazing/Dirt Correction Factor for Solar and Visible Transmittance*	

\*Used only with Daylighting:Controls

[1] Formerly, only the exterior windows in a zone could provide daylight to that zone.

## 1.15 Group – Exterior Energy Use Equipment

To facilitate the reporting of exterior consumption (to the building's heat balance/loads considerations), several objects have been included. The consumption related to these items will appear on meters specific to the items.

### 1.15.1 Exterior:Lights

#### 1.15.1.1 Field: Name

This descriptive name allows the values of exterior lights consumption to appear in the “normal” output variable list as well as the meters. It cannot be blank nor can it be duplicated by other Exterior:Lights statements.

#### 1.15.1.2 Field: Schedule Name

A schedule will allow the exterior lights consumption to be operationally different, hour to hour as well as seasonally. Fractional values in the basic schedule will be applied to the design level field below.

#### 1.15.1.3 Field: Design Level

This field (in Watts) is typically used to represent the maximum electrical input to exterior lighting fixtures that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the lighting design level could be a “diversity factor” applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour and seasonally, the design level field is constant for all simulation environments.

#### 1.15.1.4 Field: Control Option

This field is used to determine how the exterior lights are controlled. There are currently two options, ‘ScheduleNameOnly’ and ‘AstronomicalClock.’ If this field is omitted or left blank then the program will default to Schedule Name Only mode. The ‘ScheduleNameOnly’ mode dictates that the exterior lights always follow the schedule named in the field above. The ‘AstronomicalClock’ mode dictates that despite what the schedule indicates, the exterior lights will not run when the sun is up. Using the Astronomical Clock mode makes it simple to model exterior lights that are controlled by a photocell or other controller that ensures that outdoor lights will not run during the daytime. However, the Astronomical Clock control works off of the position of the sun and therefore does not operate exactly like a photocell. During the night, the schedule values are still applied in the usual way.

#### 1.15.1.5 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., “Grounds Lights”, “Facade Lights”, etc. A new meter for reporting is created for each unique subcategory (ref: Output:Meter objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the lights will be assigned to the “General” end-use subcategory.

An IDF Example:

```
Exterior:Lights,  
  OutsideLights,      !- Name  
  ON,                 !- SCHEDULE Name  
  1000,               !- Design Level

### 1.15.2 Exterior Lights Outputs

Output for exterior lights appears in three possible places. It will appear on two meters (Electricity:Facility and ExteriorLights:Electricity) as well as in its own designated value in the standard output file.

Output for exterior lights appears in three possible places. It will appear on two meters (Electricity:Facility and ExteriorLights:Electricity) as well as in its own designated value in the standard output file.

- Zone,Average,Exterior Lights Electric Power [W]
- Zone,Sum,Exterior Lights Electric Energy [J]

#### 1.15.2.1 Exterior Lights Electric Power [W]

#### 1.15.2.2 Exterior Lights Electric Energy [J]

These are the electric power and energy consumed by the exterior lights.

### 1.15.3 Exterior:FuelEquipment

#### 1.15.3.1 Field: Name

This descriptive name allows the values of exterior equipment consumption to appear in the “normal” output variable list as well as the meters. It cannot be blank nor can it be duplicated by other Exterior:FuelEquipment or Exterior:WaterEquipment statements.

#### 1.15.3.2 Field: Fuel Use Type

This field designates the appropriate meter for the exterior fuel equipment. Valid fuel types are: Electricity, NaturalGas, PropaneGas, FuelOil#1, FuelOil#2, Diesel, Gasoline, Coal, Steam, DistrictHeating, DistrictCooling, OtherFuel1 and OtherFuel2. The fuel type triggers the application of consumption amounts to the appropriate energy meters.

### 1.15.3.3 Field: Schedule Name

A schedule will allow the exterior lights consumption to be operationally different, hour to hour as well as seasonally. Fractional values in the basic schedule will be applied to the design level field below.

### 1.15.3.4 Field: Design Level

This field (Watts) is typically used to represent the maximum input to exterior fixtures that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the design level could be a "diversity factor" applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour and seasonally, the design level field is constant for all simulation environments.

### 1.15.3.5 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Fountains", etc. A new meter for reporting is created for each unique subcategory (ref: Output:Meter objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the equipment will be assigned to the "General" end-use subcategory.

IDF Examples:

```
Exterior:FuelEquipment,OutsideGasEq,Gas,ON,1000;  
Exterior:FuelEquipment,OutsideCoalEq,Coal,ON,1000;  
Exterior:FuelEquipment,OutsideFuelOil1Eq,FuelOil#1,ON,1000;  
Exterior:FuelEquipment,OutsideFuelOil2Eq,FuelOil#2,ON,1000;  
Exterior:FuelEquipment,OutsideLPGEq,PropaneGas,ON,1000;
```

## 1.15.4 Exterior:WaterEquipment

### 1.15.4.1 Field: Name

This descriptive name allows the values of exterior equipment consumption to appear in the "normal" output variable list as well as the meters. It cannot be blank nor can it be duplicated by other Exterior:FuelEquipment or Exterior:WaterEquipment statements.

### 1.15.4.2 Field: FuelUseType

For Exterior:WaterEquipment, only "Water" is current allowed for this field.

### 1.15.4.3 Field: Schedule Name

A schedule will allow the exterior water consumption to be operationally different, hour to hour as well as seasonally. Fractional values in the basic schedule will be applied to the design level field below.

### 1.15.4.4 Field: Design Level

This field (in m3/s) is typically used to represent the maximum volumetric flow for water fixtures that is then multiplied by a schedule fraction (see previous field). In EnergyPlus, this is slightly more flexible in that the exterior water equipment design level could be a "diversity factor" applied to a schedule of real numbers. Note that while the schedule value can vary from hour to hour and seasonally, the design level field is constant for all simulation environments.

### 1.15.4.5 Field: End-Use Subcategory

Allows you to specify a user-defined end-use subcategory, e.g., "Landscaping", etc. A new meter for reporting is created for each unique subcategory (ref: Output:Meter objects). Subcategories are also reported in the ABUPS table. If this field is omitted or blank, the equipment will be assigned to the "General" end-use subcategory.

IDF Example:

```
Exterior:WaterEquipment,OutsideWaterEq,Water,ON,10000;
```

## 1.15.5 Exterior Fuel Equipment, Exterior Water Equipment Outputs

Output for exterior equipment consumption appears in three possible places. It will appear on two meters (<Fuel Type>:Facility and ExteriorEquipment:<Fuel Type>) as well as in its own designated value in the standard output file, Exterior Equipment <Fuel Type> Energy. Consumption also appears on any user-defined end-use subcategory meters, i.e., <End-Use Subcategory>:ExteriorEquipment:<Fuel Type>. All outputs are in [J] except water consumption which is in [m3]. There are also rate versions

- Zone, Average, Exterior Equipment Fuel Rate [W]
- Zone,Sum, Exterior Equipment Electric Energy [J]
- Zone,Sum, Exterior Equipment Gas Energy [J]

- Zone,Average, Exterior Equipment Water Volume Flow Rate [m3/s]
- Zone,Sum, Exterior Equipment Water Volume [m3]
- Zone,Sum, Exterior Equipment Mains Water Volume [m3]
- Zone,Sum, Exterior Equipment Coal Energy [J]
- Zone,Sum, Exterior Equipment FuelOil#1 Energy [J]
- Zone,Sum, Exterior Equipment FuelOil#2 Energy [J]
- Zone,Sum, Exterior Equipment Propane Energy [J]
- Zone,Sum, Exterior Equipment Gasoline Energy [J]
- Zone,Sum, Exterior Equipment Diesel Energy [J]
- Zone,Sum, Exterior Equipment Steam Energy [J]
- Zone,Sum, Exterior Equipment OtherFuel1 Energy [J]
- Zone,Sum, Exterior Equipment OtherFuel2 Energy [J]
- Zone,Sum, Exterior Equipment District Heating Energy [J]
- Zone,Sum, Exterior Equipment District Cooling Energy [J]

#### 1.15.5.1 Exterior Equipment Fuel Rate [W]

#### 1.15.5.2 Exterior Equipment <Fuel Type> Energy [J]

These are the fuel consumption rate and energy for the exterior equipment.

#### 1.15.5.3 Exterior Equipment Water Volume Flow Rate [m3/s]

#### 1.15.5.4 Exterior Equipment Water Volume [m3]

These are the water consumption rate and volume for the exterior equipment.

Exterior Equipment Mains Water Volume [m3] This is the water volume drawn for the mains water service to serve the exterior equipment.

## 1.16 Group – Airflow

An important characteristic of energy consumption in buildings is the airflow between zones and airflow due to natural ventilation (e.g., open windows) or mechanically-induced ventilation (e.g., exhaust air fans). This group of objects describes those elements.

The AirflowNetwork model can also be used to model infiltration and mixing (zone-to-zone air flow) with or without the HVAC air distribution system operating (see Group – Airflow Network).

### 1.16.1 ZoneInfiltration:DesignFlowRate

Infiltration is the unintended flow of air from the outdoor environment directly into a thermal zone. Infiltration is generally caused by the opening and closing of exterior doors, cracks around windows, and even in very small amounts through building elements. The basic equation used to calculate infiltration with this object is:

$$Infiltration = (I_{design}) (F_{schedule}) [A + B|(T_{zone} - T_{odb})| + C(WindSpeed) + D(WindSpeed^2)] \quad (26)$$

More advanced infiltration calculations are possible using the EnergyPlus AirflowNetwork model for natural infiltration driven by wind and/or by forced air. Infiltration described by the equation shown above is entered into EnergyPlus using the following syntax. Exfiltration (the leakage of zone air to the outside) is generally handled better as zone exhaust air in the zone equipment description. The equation must always yield a non-negative results; negative values are set to 0.0.

The question of typical values for these coefficients is subject to debate. Ideally, one should do a detailed analysis of the infiltration situation and then determine a custom set of coefficients using methods such as those laid out in Chapter 26 of the ASHRAE Handbook of Fundamentals. The EnergyPlus defaults are 1,0,0,0 which give a constant volume flow of infiltration under all conditions.

BLAST (one of the EnergyPlus predecessors) used the following values as defaults: 0.606, 0.03636, 0.1177, 0. These coefficients produce a value of 1.0 at 0C deltaT and 3.35 m/s (7.5 mph) windspeed, which corresponds to a typical summer condition. At a winter condition of 40C deltaT and 6 m/s (13.4 mph) windspeed, these coefficients would increase the infiltration rate by a factor of 2.75.

In DOE-2 (the other EnergyPlus predecessor), the air change method defaults are (adjusted to SI units) 0, 0, 0.224 (windspeed), 0. With these coefficients, the summer conditions above would give a factor of 0.75, and the winter conditions would give 1.34. A windspeed of 4.47 m/s (10 mph) gives a factor of 1.0.

The source of the BLAST defaults is noted in the BLAST documentation as:

"Empirical equation and the coefficient default were determined from ASHRAE journal articles and other data on the effects of outdoor weather conditions."

The source of the DOE-2 defaults is based on examining the infiltration relationships described in the ASHRAE Handbook of Fundamentals.

The EnergyPlus example files use all of the above, the BLAST defaults in some (e.g., GeometryTest), the DOE-2 defaults in some (e.g., 5ZoneAirCooled), and the EnergyPlus defaults in some (e.g., LgOffVAVDetCoil).

The local outdoor dry-bulb temperature used in the above basic equation ( $T_{db}$ ) is typically a function of the height of the zone centroid above ground. The corresponding zone name is given in the second field. The local outdoor dry-bulb temperature calculation procedure is given in the section of "Local Outdoor Air Temperature Calculation" in the Engineering Reference.

The local outdoor wind speed used in the above basic equation (WindSpeed) is also a function of the height of the zone centroid above ground. The corresponding zone name is given in the second field. The local outdoor wind speed calculation procedure is given in the section of "Local Wind Speed Calculation" in the Engineering Reference.

Note: When the value of the Wind Speed Profile Exponent field in the Site:HeightVariation is equal to 0.0. The local wind speed is always equal to the wind speed given in the weather data and will not be dependent on zone centroid height. Similarly, if the value of the Air Temperature Gradient Coefficient is set equal to 0 the local air dry-bulb temperature is also always equal to the air dry-bulb temperature given in the weather data and will not be dependent on zone centroid height.

One or more infiltration objects can be defined for each zone, and the resulting infiltration rate for the zone will simply be the summation of the flow rates specified by the infiltration objects.

#### 1.16.1.1 Field: Name

The name of the ZoneInfiltration:DesignFlowRate object. This needs to be unique across all different ZoneInfiltration objects.

#### 1.16.1.2 Field: Zone or ZoneList Name

This field is the name of the zone (ref: Zone) or ZoneList (ref: ZoneList) and attaches a particular infiltration statement to a thermal zone or set of thermal zones in the building. When the ZoneList option is used then this infiltration definition is applied to each of the zones in the zone list effecting a global definition for the amount of infiltration flow rate in the zone. The Zonelist option can be used effectively with the flow/area, flow/exteriorarea, flow/exteriorwallarea, or airchanges/hour of the Design Flow Rate Calculation Method.

The name of the actual infiltration object becomes <Zone Name> <ZoneInfiltration:DesignFlowRate Object Name> and should be less than the standard length (100 characters) for a name field. If it is greater than this standard length, it may be difficult to specify in output reporting as it will be truncated. A warning will be shown if the generated name is greater than 100 characters. If it duplicates another such concatenated name, there will be a severe error and terminate the run.

#### 1.16.1.3 Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design volume flow rate ( $\dot{V}_{design}$ ) (see Design Flow Rate Calculation Method field and related subsequent fields). This fraction between 0.0 and 1.0 is noted as  $F_{schedule}$  in the above equation.

#### 1.16.1.4 Field: Design Flow Rate Calculation Method

This field is a key/choice field that tells which of the next four fields are filled and is descriptive of the method for calculating the design volume flow rate. The key/choices are:

- Flow/Zone

With this choice, the method used will be a straight insertion of the design volume flow rate. (The Design Flow Rate field should be filled.)

- Flow/Area

With this choice, the method used will be a factor per floor area of the zone. (The flow per Zone Area field should be filled).

- Flow/ExteriorArea

With this choice, the method used will be a factor per exterior surface area of the zone. (The flow per Exterior Surface Area field should be filled).

- Flow/ExteriorWallArea

With this choice, the method used will be a factor per exterior wall surface area of the zone. (The flow per Exterior Surface Area field should be filled).

- AirChanges/Hour

With this choice, the method used will be the number of air changes per hour for the infiltration amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. (The Air Changes per Hour field should be filled).

#### 1.16.1.5 Field: Design Flow Rate

This field denotes the full design volume flow rate ( $m^3/s$ ). The previous field should choose "flow/zone" as the choice. The design volume flow rate (noted as  $I_{design}$  in the above equation) is the maximum amount of infiltration expected at design conditions. The design value is modified by the schedule fraction (see Field:Schedule Name) and user specified coefficients (see "coefficient" fields below). The resulting volume flow rate is converted to mass flow using the current outdoor air density at each time step.

#### 1.16.1.6 Field: Flow per Zone Floor Area

This factor ( $m^3/s-m^2$ ) is used, along with the Zone Area to determine the maximum Design Flow Rate as described in the Design Flow Rate field. The choice from the method field should be "Flow/Area".

#### 1.16.1.7 Field: Flow per Exterior Surface Area

This factor ( $m^3/s-m^2$ ) is used, along with the Exterior Surface Area in the Zone to determine the maximum Design Flow Rate as described in the Design Flow Rate field. The choice from the method field should be "Flow/Exteriorarea" or "Flow/ExteriorWallArea".

#### 1.16.1.8 Field: Air Changes per Hour

This factor is used, along with the Zone Volume to determine the maximum Design Flow Rate as described in the Design Flow Rate field. The choice from the method field should be "AirChanges/Hour".

#### 1.16.1.9 Field: Constant Term Coefficient

This number is the "A" parameter in the above infiltration equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter, however, is a constant under all conditions and is not modified by any environmental effect. As a result, it is dimensionless.

#### 1.16.1.10 Field: Temperature Term Coefficient

This number is the "B" parameter in the above infiltration equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the temperature difference between the outdoor and indoor air dry-bulb temperatures. The units for this parameter are inverse Celsius.

#### 1.16.1.11 Field: Velocity Term Coefficient

This number is the "C" parameter in the above infiltration equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the speed of wind being experienced outside the building. The units for this parameter are s/m.

#### 1.16.1.12 Field: Velocity Squared Term Coefficient

This number is the "D" parameter in the above infiltration equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by square of the speed of wind being experienced outside the building. The units for this parameter are  $s^2/m^2$ .

### 1.16.2 ZoneInfiltration:EffectiveLeakageArea

ZoneInfiltration:EffectiveLeakageArea model is similar to the other infiltration objects but uses a different equation to model the unintended flow of air from the outdoor environment directly into a thermal zone. Infiltration is generally caused by the opening and closing of exterior doors, cracks around windows, and even in very small amounts through building elements. This model is based on work by Sherman and Grimsrud (1980) and is appropriate for smaller, residential-type buildings. The equation used to calculate infiltration in the effective leakage area model is:

$$Infiltration = (F_{Schedule}) \frac{A_L}{1000} \sqrt{C_s \Delta T + C_w (WindSpeed)^2} \quad (27)$$

where  $\Delta T$  is the average difference between zone air temperature and the outdoor air temperature and the other coefficients are described below.

Note that the coefficients for the "EffectiveLeakageArea" model are not interchangeable with the similarly named coefficients in the "FlowCoefficient" model (see ZoneInfiltration:FlowCoefficient object).

One or more infiltration objects of different types can be defined for each zone, and the resulting infiltration rate for the zone will simply be the summation of the flow rates specified by the infiltration objects.

#### 1.16.2.1 Field: Name

The name of the ZoneInfiltration:EffectiveLeakageArea object. This needs to be unique across all different ZoneInfiltration objects.

#### 1.16.2.2 Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a particular infiltration statement to a thermal zone in the building.

#### 1.16.2.3 Field: Schedule Name

This field is the name of a schedule (ref: Schedule) that modifies the volume flow rate calculated by the model. This fraction between 0.0 and 1.0 is noted as  $F_{schedule}$  in the above equation.

#### 1.16.2.4 Field: Effective Air Leakage Area

This field is the effective air leakage area, in  $cm^2$ , at 4 Pa. This is the value  $A_L$  in the equation above. Effective leakage area data can be obtained from a whole-building pressure test (eg. blower door test). ASHRAE Handbook of Fundamentals also lists typical values component leakage areas for low-rise residential (e.g. Table 1 in Chapter 26 of HoF 2001). The value should correspond to a pressure difference of 4 Pa.

#### 1.16.2.5 Field: Stack Coefficient

This field is the value of the stack coefficient,  $C_s$  in the equation above. The coefficient has units of  $(L/s)^2/(cm^4 \cdot K)$ . Values for the "Basic Model Stack Coefficient" listed in the ASHRAE Handbook of Fundamentals (2005 and 2001) are:

One story house	Two story house	Three story house
0.000145	0.000290	0.000435

#### 1.16.2.6 Field: Wind Coefficient

This field is the value of the wind coefficient,  $C_w$  in the equation above. The coefficient has units of  $(L/s)^2/(cm^4 \cdot (m/s)^2)$ . Values for the "Basic Model Wind Coefficient" listed in the ASHRAE Handbook of Fundamentals (2005 chapter 27; 2001, Chapter 26) depend on the type of shelter and are listed in the following tables.

Shelter class	One story house	Two story house	Three story house
1	0.000319	0.000420	0.000494
2	0.000246	0.000325	0.000382
3	0.000174	0.000231	0.000271

4	0.000104	0.000137	0.000161
5	0.000032	0.000042	0.000049

Shelter class	Description
1	No obstructions or local shielding
2	Typical shelter for an isolated rural house
3	Typical shelter caused by other buildings across the street
4	Typical shelter for urban buildings on larger lots
5	Typical shelter produced by buildings that are immediately adjacent.

An example IDF object is

```

  0.000145,                !- Stack Coefficient
  0.000174 ;              !- Wind Coefficient
```

### 1.16.3 ZoneInfiltration:FlowCoefficient

ZoneInfiltration:FlowCoefficient model is similar to the other infiltration objects but uses a different equation to model the unintended flow of air from the outdoor environment directly into a thermal zone. Infiltration is generally caused by the opening and closing of exterior doors, cracks around windows, and even in very small amounts through building elements. This reformulated model is based on the AIM-2 model by Walker and Wilson (1998) and is appropriate for smaller, residential-type buildings. The equation used to calculate infiltration in the flow coefficient model is:

$$Infiltration = (F_{Schedule}) \sqrt{(cC_s \Delta T^n)^2 + (cC_w (s * WindSpeed)^{2n})^2} \quad (28)$$

Where  $\Delta T$  is the average difference between zone air temperature and the outdoor air temperature and the other coefficients are described below.

Note that the coefficients for the “Flow Coefficient” model are not interchangeable with the similarly named coefficients in the “Effective Leakage Area” model (see ZoneInfiltration:EffectiveLeakageArea object).

One or more infiltration objects of different types can be defined for each zone, and the resulting infiltration rate for the zone will simply be the summation of the flow rates specified by the infiltration objects.

#### 1.16.3.1 Field: Name

The name of the ZoneInfiltration:FlowCoefficient object. This needs to be unique across all different ZoneInfiltration objects.

#### 1.16.3.2 Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a particular infiltration statement to a thermal zone in the building.

#### 1.16.3.3 Field: Schedule Name

This field is the name of a schedule (ref: Schedule) that modifies the volume flow rate calculated by the model. This fraction between 0.0 and 1.0 is noted as  $F_{schedule}$  in the above equation.

#### 1.16.3.4 Field: Flow Coefficient

This field is the flow coefficient in  $m^3/(s \cdot Pa^n)$ . This is the value  $c$  in the equation above. The flow coefficient can be determined from the effective leakage area and whole-building pressure tests (eg. blower door test).

#### 1.16.3.5 Field: Stack Coefficient

This field is the value of the stack coefficient,  $C_s$  in the equation above. The coefficient has units of  $(Pa/K)^n$ . Values for the “Enhanced Model Stack Coefficient” listed in the ASHRAE Handbook of Fundamentals (2005 and 2001) are:

	One story house	Two story house	Three story house
With Flue	0.069	0.089	0.107
No Flue	0.054	0.078	0.098

### 1.16.3.6 Field: Pressure Exponent

This field is the value of the pressure exponent,  $n$  in the equation above. The pressure exponent generally lies between 0.6 and 0.7 with a typical value of 0.67 for the enhanced model.

### 1.16.3.7 Field: Wind Coefficient

This field is the value of the wind coefficient,  $C_w$  in the equation above. The coefficient has units of  $(\text{Pa} \cdot \text{s}^2/\text{m}^2)^n$ . Values for the “Enhanced Model Wind Coefficient” listed in the ASHRAE Handbook of Fundamentals (2005 and 2001) are:

	One story house	Two story house	Three story house
Basement/slab; With Flue	0.142	0.156	0.167
Basement/slab; No Flue	0.156	0.170	0.170
Crawlspace; With Flue	0.128	0.142	0.154
Crawlspace; No Flue	0.128	0.142	0.151

### 1.16.3.8 Field: Shelter Factor

This field is the value of the wind coefficient,  $s$  in the equation above. The coefficient is dimensionless. Values for the “Enhanced Model Shelter Factor” listed in the ASHRAE Handbook of Fundamentals (2005 and 2001) are:

Shelter class	No Flue	One story house with flue	Two story house with flue	Three story house with flue
1	1.00	1.10	1.07	1.06
2	0.90	1.02	0.98	0.97
3	0.70	0.86	0.81	0.79
4	0.50	0.70	0.64	0.61
5	0.30	0.54	0.47	0.43

Shelter class	Description
1	No obstructions or local shielding
2	Typical shelter for an isolated rural house
3	Typical shelter caused by other buildings across the street
4	Typical shelter for urban buildings on larger lots
5	Typical shelter produced by buildings that are immediately adjacent.

An Example IDF object is:

- HVAC,Sum,Zone Infiltration Total Heat Gain Energy [J]
- HVAC,Average,Zone Infiltration Current Density Volume Flow Rate [m3/s]
- HVAC,Average,Zone Infiltration Standard Density Volume Flow Rate [m3/s]

- HVAC,Sum,Zone Infiltration Current Density Volume [m3]
- HVAC,Sum,Zone Infiltration Standard Density Volume [m3]
- HVAC,Sum,Zone Infiltration Mass [kg]
- HVAC,Sum,Zone Infiltration Mass Flow Rate [kg/s]
- HVAC,Average,Zone Infiltration Air Change Rate [ach]

Note: If ZoneInfiltration:\* objects and ZoneAirBalance:OutdoorAir (with Air Balance Method = Quadrature) objects reference the same Zone Name, the above infiltration output variables will not be reported for that zone. Instead, output variables for zone outdoor air flow will be reported by the corresponding ZoneAirBalance:OutdoorAir object.

#### **1.16.4.1 Zone Infiltration Sensible Heat Loss Energy [J]**

The sensible (temperature) heat loss that occurs when the infiltration air temperature (outdoor) < zone air temperature.

#### **1.16.4.2 Zone Infiltration Sensible Heat Gain Energy [J]**

The sensible (temperature) heat gain that occurs when the infiltration air temperature (outdoor) >= zone air temperature.

#### **1.16.4.3 Zone Infiltration Latent Heat Loss Energy [J]**

The latent heat loss that occurs when the infiltration air humidity ratio (outdoor) < zone air humidity ratio.

#### **1.16.4.4 Zone Infiltration Latent Heat Gain Energy [J]**

The latent heat gain that occurs when the infiltration air humidity ratio (outdoor) >= zone air humidity ratio.

#### **1.16.4.5 Zone Infiltration Total Heat Loss Energy [J]**

The total heat loss that occurs when the sum of Zone Infiltration Sensible Heat Gain Energy and Zone Infiltration Latent Heat Gain Energy < the sum of Zone Infiltration Sensible Heat Loss Energy and Zone Infiltration Latent Heat Loss Energy.

#### **1.16.4.6 Zone Infiltration Total Heat Gain Energy [J]**

The total heat gain that occurs when the sum of Zone Infiltration Sensible Heat Gain Energy and Zone Infiltration Latent Heat Gain Energy >= the sum of Zone Infiltration Sensible Heat Loss Energy and Zone Infiltration Latent Heat Loss Energy.

#### **1.16.4.7 Zone Infiltration Current Density Volume [m3]**

#### **1.16.4.8 Zone Infiltration Current Density Volume Flow Rate [m3/s]**

These outputs are the total volume and volume flow rate of infiltration air based on the current density of zone air.

#### **1.16.4.9 Zone Infiltration Standard Density Volume [m3]**

#### **1.16.4.10 Zone Infiltration Standard Density Volume Flow Rate [m3/s]**

These outputs are the total volume and volume flow rate of infiltration air based on the standard density of air. Standard density in EnergyPlus corresponds to 20°C drybulb, dry air, and nominally adjusted for elevation.

#### **1.16.4.11 Zone Infiltration Mass [kg]**

The mass flow of the Infiltration air.

#### **1.16.4.12 Zone Infiltration Mass Flow Rate [kg/s]**

The mass flow rate of the Infiltration air.

#### **1.16.4.13 Zone Infiltration Air Change Rate [ach]**

The rate of infiltration in air changes per hour.

### **1.16.5 ZoneVentilation:DesignFlowRate**

Ventilation is the purposeful flow of air from the outdoor environment directly into a thermal zone in order to provide some amount of non-mechanical cooling. Ventilation, as specified by the input syntax for the ZoneVentilation:DesignFlowRate object, is intended to model "simple" ventilation as opposed to the more

detailed ventilation investigations that can be performed with the AirflowNetwork model or with air systems that have outdoor air mixers. Zone ventilation, as specified via this input object, can be controlled by a schedule and through the specification of minimum, maximum and delta temperatures as described below. The temperatures can be either single constant values for the entire simulation or schedules which can vary over time. As with infiltration, the actual flow rate of ventilation air can be modified by the temperature difference between the inside and outside environment and the wind speed. The basic equation used to calculate ventilation with this model is:

$$Ventilation = (V_{design}) (F_{schedule}) [A + B |T_{zone} - T_{odb}| + C (WindSpeed) + D (WindSpeed^2)] \quad (29)$$

Similar to infiltration, the question of typical values for these coefficients is subject to debate. Ideally, one should do a detailed analysis of the ventilation situation and then determine a custom set of coefficients using methods such as those laid out in Chapter 26 of the ASHRAE Handbook of Fundamentals. The EnergyPlus defaults are 1,0,0,0 which give a constant volume flow of ventilation under all conditions. The following discussion is duplicated from the infiltration design flow rate object. The equation must always yield a non-negative results; negative values are set to 0.0.

BLAST (one of the EnergyPlus predecessors) used the following values as defaults: 0.606, 0.03636, 0.1177, 0. These coefficients produce a value of 1.0 at 0C deltaT and 3.35 m/s (7.5 mph) windspeed, which corresponds to a typical summer condition. At a winter condition of 40C deltaT and 6 m/s (13.4 mph) windspeed, these coefficients would increase the infiltration rate by a factor of 2.75.

In DOE-2 (the other EnergyPlus predecessor), the air change method defaults are (adjusted to SI units) 0, 0, 0.224 (windspeed), 0. With these coefficients, the summer conditions above would give a factor of 0.75, and the winter conditions would give 1.34. A windspeed of 4.47 m/s (10 mph) gives a factor of 1.0.

The source of the BLAST defaults is noted in the BLAST documentation as:

"Empirical equation and the coefficient default were determined from ASHRAE journal articles and other data on the effects of outdoor weather conditions."

The source of the DOE-2 defaults is based on examining the *infiltration* relationships described in the ASHRAE Handbook of Fundamentals.

The local outdoor dry-bulb temperature used in the above basic equation ( $T_{db}$ ) is typically a function of the height of the zone centroid above ground. The corresponding zone name is given in the second field. The local outdoor dry-bulb temperature calculation procedure is described in the "Local Outdoor Air Temperature Calculation" section of the Engineering Reference.

The local outdoor wind speed used in the above basic equation (WindSpeed) is also a function of the height of the zone centroid above ground. The corresponding zone name is given in the second field. The local outdoor wind speed calculation procedure is described in the "Local Wind Speed Calculation" section of the Engineering Reference.

Note: When the value of the Wind Speed Profile Exponent field in the Site:HeightVariation object is equal to 0.0, the local wind speed is always equal to the wind speed given in the weather data and will not be dependent on zone centroid height. Similarly, if the value of the Air Temperature Gradient Coefficient is set equal to 0, the local air dry-bulb temperature is also always equal to the air dry-bulb temperature given in the weather data and will not be dependent on zone centroid height.

One or more ventilation objects (i.e., ZoneVentilation:DesignFlowRate and/or ZoneVentilation:WindandStackOpenArea) can be defined for each zone, and the resulting ventilation rate for the zone will simply be the summation of the flow rates specified by the ventilation objects.

More advanced ventilation calculations are possible using the EnergyPlus AirflowNetwork model.

#### 1.16.5.1 Field: Name

The name of the ZoneVentilation:DesignFlowRate object.

#### 1.16.5.2 Field: Zone or ZoneList Name

This field is the name of the zone (ref: Zone) or ZoneList (ref: ZoneList) and attaches a particular ventilation statement to a thermal zone or set of thermal zones in the building. When the ZoneList option is used then this ventilation definition is applied to each of the zones in the zone list effecting a global definition for the amount of infiltration flow rate in the zone. The Zonelist option can be used effectively with the flow/area, flow/person, or airchanges/hour of the Design Flow Rate Calculation Method.

The name of the actual ventilation object becomes <Zone Name> <ZoneVentilation:DesignFlowRate Object Name> and should be less than the standard length (100 characters) for a name field. If it is greater than this standard length, it may be difficult to specify in output reporting as it will be truncated. A warning will be shown if the generated name is greater than 100 characters. If it duplicates another such concatenated name, there will be a severe error and terminate the run.

#### 1.16.5.3 Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design volume flow rate ( $V_{design}$ ) (see Design Flow Rate Calculation Method field and related subsequent fields). This fraction between 0.0 and 1.0 is noted as  $F_{schedule}$  in the above equation.

#### 1.16.5.4 Field: Design Flow Rate Calculation Method

This field is a key/choice field that tells which of the next four fields are filled and is descriptive of the method for calculating the design volume flow rate. The key/choices are:

- Flow/Zone

With this choice, the method used will be a straight insertion of the design volume flow rate. (The Design Flow Rate field should be filled.)

- Flow/Area

With this choice, the method used will be a factor per floor area of the zone. (The Flow per Zone Floor Area field should be filled).

- Flow/Person

With this choice, the method used will be a factor per nominal number of people in the zone. (The Flow per Person field should be filled).

- AirChanges/Hour

With this choice, the method used will be the number of air changes per hour for the infiltration amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. (The Air Changes per Hour field should be filled).

#### **1.16.5.5 Field: Design Flow Rate**

This field denotes the full design volume flow rate ( $m^3/s$ ). The previous field should choose “flow/zone” as the choice. The design volume flow rate (noted as  $V_{\text{design}}$  in the above equation) is the maximum amount of ventilation expected at design conditions. The design value is modified by the schedule fraction (see Field: Schedule Name) and user specified coefficients (see four “coefficient” fields below).

#### **1.16.5.6 Field: Flow Rate per Zone Floor Area**

This factor ( $m^3/s\cdot m^2$ ) is used, along with the Zone Area to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “flow/area”.

#### **1.16.5.7 Field: Flow Rate per Person**

This factor ( $m^3/s\cdot\text{person}$ ) is used, along with the nominal (maximum) number of occupants (people) in the Zone to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “flow/person”.

#### **1.16.5.8 Field: Air Changes per Hour**

With this choice, the method used will be the number of air changes per hour for the ventilation amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. The choice from the method field should be “AirChanges/Hour”.

#### **1.16.5.9 Field: Ventilation Type**

This alpha character string defines the type of ventilation as one of the following options: Natural, Exhaust, Intake, or Balanced. Natural ventilation is assumed to be air movement/exchange as a result of openings in the building façade and will not consume any fan energy. Values for fan pressure and efficiency for natural ventilation are ignored. For either Exhaust or Intake, values for fan pressure and efficiency define the fan electric consumption. For Natural and Exhaust ventilation, the conditions of the air entering the space are assumed to be equivalent to outside air conditions. For Intake and Balanced ventilation, an appropriate amount of fan heat is added to the entering air stream. For Balanced ventilation, both an intake fan and an exhaust fan are assumed to co-exist, both having the same flow rate and power consumption (using the entered values for fan pressure rise and fan total efficiency). Thus, the fan electric consumption for Balanced ventilation is twice that for the Exhaust or Intake ventilation types which employ only a single fan.

#### **1.16.5.10 Field: Fan Pressure Rise**

This is the pressure rise experienced across the fan in Pascals ( $N/m^2$ ). This is a function of the fan and plays a role in determining the amount of energy consumed by the fan.

#### **1.16.5.11 Field: Fan Total Efficiency**

This value is the overall efficiency of the fan, i.e., the ratio of the power delivered to the fluid to the electrical input power. It is the product of the motor efficiency and the impeller efficiency. The motor efficiency is the power delivered to the shaft divided by the electrical power input to the motor. The impeller efficiency is power delivered to the fluid (air) divided by the shaft power. The power delivered to the fluid is the mass flow rate of the air multiplied by the pressure rise divided by the air density. This input value must be between 0 and 1."

#### **1.16.5.12 Field: Constant Term Coefficient**

This number is the “A” parameter in the above ventilation equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter, however, is a constant under all conditions and is not modified by any environmental effect. As a result, it is dimensionless.

#### **1.16.5.13 Field: Temperature Term Coefficient**

This number is the “B” parameter in the above ventilation equation. It is part of the user specified modifying parameters that are a function of environmental

factors. This parameter is modified by the temperature difference between the outdoor and indoor air dry-bulb temperatures. The units for this parameter are inverse Celsius.

#### **1.16.5.14 Field: Velocity Term Coefficient**

This number is the "C" parameter in the above ventilation equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the speed of wind being experienced outside the building. The units for this parameter are s/m.

#### **1.16.5.15 Field: Velocity Squared Term Coefficient**

This number is the "D" parameter in the above ventilation equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by square of the speed of wind being experienced outside the building. The units for this parameter are s<sup>2</sup>/m<sup>2</sup>.

#### **1.16.5.16 Field: Minimum Indoor Temperature**

This is the indoor temperature (in Celsius) below which ventilation is shutoff. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is -100.0°C if the field is left blank. This lower temperature limit is intended to avoid overcooling a space and thus result in a heating load. For example, if the user specifies a minimum temperature of 20°C, ventilation is assumed to be available if the zone air temperature is above 20°C. If the zone air temperature drops below 20°C, then ventilation is automatically turned off.

#### **1.16.5.17 Field: Minimum Indoor Temperature Schedule Name**

This alpha field defines the name of a schedule (ref. Schedule objects) which contains the minimum indoor temperature (in Celsius) below which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Minimum Indoor Temperature field. If the user enters a valid schedule name, the minimum temperature values specified in this schedule will override the constant value specified in the Minimum Indoor Temperature field.

#### **1.16.5.18 Field: Maximum Indoor Temperature**

This is the indoor temperature (in Celsius) above which ventilation is shutoff. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is 100.0°C if the field is left blank. This upper temperature limit is intended to avoid overheating a space and thus result in a cooling load. For example, if the user specifies a maximum temperature of 28°C, ventilation is assumed to be available if the zone air temperature is below 28°C. If the zone air temperature increases to 28°C, then ventilation is automatically turned off.

#### **1.16.5.19 Field: Maximum Indoor Temperature Schedule Name**

This alpha field defines the name of a schedule (ref. Schedule objects) which contains the maximum indoor temperature (in Celsius) above which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Maximum Indoor Temperature field. If the user enters a valid schedule name, the maximum temperature values specified in this schedule will override the constant value specified in the Maximum Indoor Temperature field.

#### **1.16.5.20 Field: Delta Temperature**

This is the temperature difference (in Celsius) between the indoor and outdoor air dry-bulb temperatures below which ventilation is shutoff. The minimum value for this field is -100.0°C and the default value is also -100.0°C if the field is left blank. This field allows ventilation to be stopped if the temperature outside is too warm and could potentially heat the space. For example, if the user specifies a delta temperature of 2°C, ventilation is assumed to be available if the outside air temperature is at least 2°C cooler than the zone air temperature. If the outside air dry-bulb temperature is less than 2°C cooler than the indoor dry-bulb temperature, then ventilation is automatically turned off.

The values for this field can include negative numbers. This allows ventilation to occur even if the outdoor temperature is above the indoor temperature. The Delta Temperature is used in the code in the following way:

IF ((IndoorTemp - OutdoorTemp) < DeltaTemperature) Then ventilation is not allowed.

Thus, if a large negative number is input for DeltaTemperature, the ventilation can be kept on even if the outdoor temperature is greater than the indoor temperature. This is useful for uncontrolled natural ventilation (open windows) or as a way to estimate the effect of required ventilation air for load calculations.

#### **1.16.5.21 Field: Delta Temperature Schedule Name**

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the temperature difference (in Celsius) between the indoor and outdoor air dry-bulb temperatures below which ventilation is shutoff as a function of time. The minimum temperature difference value in the schedule can be -100°C. This field is an optional field and has the same functionality as the Delta Temperature field. If the user enters a valid schedule name, the delta temperature values specified in this schedule will override the constant value specified in the Delta Temperature field.

#### **1.16.5.22 Field: Minimum Outdoor Temperature**

This is the outdoor temperature (in Celsius) below which ventilation is shut off. The minimum value for this field is -100.0°C and the maximum value is 100.0°C.

The default value is -100.0°C if the field is left blank. This lower temperature limit is intended to avoid overcooling a space, which could result in a heating load.

#### 1.16.5.23 Field: Minimum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum outdoor temperature (in Celsius) below which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Minimum Outdoor Temperature field. If the user enters a valid schedule name, the temperature values in this schedule will override the constant value specified in the Minimum Outdoor Temperature field.

#### 1.16.5.24 Field: Maximum Outdoor Temperature

This is the outdoor temperature (in Celsius) above which ventilation is shut off. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is 100.0°C if the field is left blank. This upper temperature limit is intended to avoid overheating a space, which could result in a cooling load.

#### 1.16.5.25 Field: Maximum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum outdoor temperature (in Celsius) above which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Maximum Outdoor Temperature field. If the user enters a valid schedule name, the temperature values in this schedule will override the constant value specified in the Maximum Outdoor Temperature field.

#### 1.16.5.26 Field: Maximum Wind Speed

This is the wind speed (m/s) above which ventilation is shut off. This can help simulate conditions where one would normally close windows to avoid chaos in a space (papers blowing around, etc.).

### 1.16.6 ZoneVentilation:WindandStackOpenArea

For this model, the ventilation air flow rate is a function of wind speed and thermal stack effect, along with the area of the opening being modeled. This object can be used alone or in combination with ZoneVentilation:DesignFlowRate objects. This model is intended for simplified ventilation calculations as opposed to the more detailed ventilation investigations that can be performed with the AirflowNetwork model. Using the “Wind and Stack with Open Area” model, the natural ventilation flow rate can be controlled by a multiplier fraction schedule applied to the user-defined opening area and through the specification of minimum, maximum and delta temperatures. The temperatures can be either single constant values for the entire simulation or schedules which can vary over time. The equation used to calculate the ventilation rate driven by wind is:

$$Q_w = C_w A_{opening} F_{schedule} V \quad (30)$$

where,

$Q_w$  = Volumetric air flow rate driven by wind [m<sup>3</sup>/s]

$C_w$  = Opening effectiveness [dimensionless]

$A_{opening}$  = Opening area [m<sup>2</sup>]

$F_{schedule}$  = Open area fraction [user-defined schedule value, dimensionless]

$V$  = Local wind speed [m/s]

The equation used to calculate the ventilation rate due to stack effect is:

$$Q_s = C_D A_{opening} F_{schedule} \sqrt{2g\Delta H_{NPL} (|T_{zone} - T_{odb}|/T_{zone})} \quad (31)$$

where,

$Q_s$  = Volumetric air flow rate due to stack effect [m<sup>3</sup>/s]

$C_D$  = Discharge coefficient for opening [dimensionless]

$A_{opening}$  = Opening area [m<sup>2</sup>]

$F_{schedule}$  = Open area fraction [user-defined schedule value, dimensionless]

$\Delta H_{NPL}$  = Height from midpoint of lower opening to the neutral pressure level [m].

Estimation of this value is difficult; refer to Chapter 16 of the 2009 ASHRAE Handbook of Fundamentals for guidance.

$T_{zone}$  = Zone air dry-bulb temperature [K]

$T_{odb}$  = Local outdoor air dry-bulb temperature [K]

The total ventilation rate calculated by this model is the quadrature sum of the wind and stack air flow components:

$$Ventilation_{WindAndStack} = \sqrt{Q_s^2 + Q_w^2} \quad (32)$$

The local outdoor air dry-bulb temperature used in the stack effect equation ( $T_{odb}$ ) is typically a function of the height of the zone centroid above ground. The corresponding zone name is given in the second field. The local outdoor air dry-bulb temperature calculation procedure is described in the "Local Outdoor Air Temperature Calculation" section of the Engineering Reference.

The local outdoor wind speed used in the above wind-driven equation ( $V$ ) is also a function of the height of the zone centroid above ground. The corresponding zone name is given in the second field. The local outdoor wind speed calculation procedure is described in the "Local Wind Speed Calculation" section of the Engineering Reference.

Note: When the value of the Wind Speed Profile Exponent field in the Site:HeightVariation object is equal to 0.0, the local wind speed is always equal to the wind speed given in the weather data and will not be dependent on zone centroid height. Similarly, if the value of the Air Temperature Gradient Coefficient is set equal to 0, the local air dry-bulb temperature is also always equal to the air dry-bulb temperature given in the weather data and will not be dependent on zone centroid height.

One or more ventilation objects (i.e., ZoneVentilation:DesignFlowRate and/or ZoneVentilation:WindandStackOpenArea) can be defined for each zone, and the resulting ventilation rate for the zone will simply be the summation of the flow rates specified by the ventilation objects.

More advanced ventilation calculations are possible using the EnergyPlus AirflowNetwork model.

#### 1.16.6.1 Field: Name

The name of the ZoneVentilation:WindandStackOpenArea object.

#### 1.16.6.2 Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a particular ventilation statement to a thermal zone in the building.

#### 1.16.6.3 Field: Opening Area

This is the opening area exposed to outdoors ( $m^2$ ) in a zone.

#### 1.16.6.4 Field: Opening Area Fraction Schedule Name

This field is the name of the schedule (ref: Schedule) which modifies the Opening Area value (see previous field). The schedule values must be any positive number between 0 and 1 as a fraction. The actual opening area in a zone for a particular simulation time step is defined as the product of the Opening Area input field and the value specified by the schedule named in this input field.

#### 1.16.6.5 Field: Opening Effectiveness

This field is the opening effectiveness ( $C_w$ ). The value must be between 0.0 and 1.0 or the value can be autocalculated. If a real value is input, that constant value will be used in the calculations. Otherwise, this field can be left blank (default = Autocalculate) or the user can input **Autocalculate**. Based on recommended values provided in Chapter 16 of the 2009 ASHRAE Handbook of Fundamentals,  $C_w = 0.55$  for perpendicular winds and  $C_w = 0.3$  for diagonal winds. For Autocalculate, any angles between perpendicular and diagonal are linearly interpolated between 0.3 and 0.55 by the model.

#### 1.16.6.6 Field: Effective Angle

This is the angle in degrees counting from the North clockwise to the opening outward normal. The value must be between 0 and 360, with the default being 0 if this input field is left blank. The Effective Angle is 0 if the opening outward normal faces North, 90 if faces East, 180 if faces South, and 270 if faces West. The value is fixed and independent of coordinate system defined in the GlobalGeometryRules object. This input field value is used to calculate the angle between the wind direction and the opening outward normal to determine the opening effectiveness values when the input field Opening Effectiveness = Autocalculate.

#### 1.16.6.7 Field: Height Difference

This is the height difference between the midpoint of the lower opening and the neutral pressure level in meters. This value is a required user input.

Note: Estimation of the height difference is difficult for natural ventilated buildings. Chapter 16 of the 2009 ASHRAE Handbook of Fundamentals may provide guidance for estimating the height difference.

#### 1.16.6.8 Field: Discharge Coefficient for Opening

This is the discharge coefficient for the opening ( $C_D$ ). The value must be between 0.0 and 1.0, or the value can be autocalculated. If a real value is input, that constant value will be used in the calculations. Otherwise, this field can be left blank (default = Autocalculate) or the user can input **Autocalculate**. For Autocalculate, the program will determine the discharge coefficient based on the following equation:

$$C_D = 0.40 + 0.0045 |T_{zone} - T_{odb}| \quad (33)$$

#### 1.16.6.9 Field: Minimum Indoor Temperature

This is the indoor temperature (in Celsius) below which ventilation is shutoff. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is -100.0°C if the field is left blank. This lower temperature limit is intended to avoid overcooling a space and thus result in a heating load. For example, if the user specifies a minimum temperature of 20°C, ventilation is assumed to be available if the zone air temperature is above 20°C. If the zone air temperature drops below 20°C, then ventilation is automatically turned off.

#### 1.16.6.10 Field: Minimum Indoor Temperature Schedule Name

This alpha field defines the name of a schedule (ref. Schedule objects) which contains the minimum indoor temperature (in Celsius) below which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Minimum Indoor Temperature field. If the user enters a valid schedule name, the minimum temperature values specified in this schedule will override the constant value specified in the Minimum Indoor Temperature field.

#### 1.16.6.11 Field: Maximum Indoor Temperature

This is the indoor temperature (in Celsius) above which ventilation is shutoff. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is 100.0°C if the field is left blank. This upper temperature limit is intended to avoid overheating a space and thus result in a cooling load. For example, if the user specifies a maximum temperature of 28°C, ventilation is assumed to be available if the zone air temperature is below 28°C. If the zone air temperature increases to 28°C, then ventilation is automatically turned off.

#### 1.16.6.12 Field: Maximum Indoor Temperature Schedule Name

This alpha field defines the name of a schedule (ref. Schedule objects) which contains the maximum indoor temperature (in Celsius) above which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Maximum Indoor Temperature field. If the user enters a valid schedule name, the maximum temperature values specified in this schedule will override the constant value specified in the Maximum Indoor Temperature field.

#### 1.16.6.13 Field: Delta Temperature

This is the temperature difference (in Celsius) between the indoor and outdoor air dry-bulb temperatures below which ventilation is shutoff. The minimum value for this field is -100.0°C and the default value is also -100.0°C if the field is left blank. This field allows ventilation to be stopped if the temperature outside is too warm and could potentially heat the space. For example, if the user specifies a delta temperature of 2°C, ventilation is assumed to be available if the outside air temperature is at least 2°C cooler than the zone air temperature. If the outside air dry-bulb temperature is less than 2°C cooler than the indoor dry-bulb temperature, then ventilation is automatically turned off.

The values for this field can include negative numbers. This allows ventilation to occur even if the outdoor temperature is above the indoor temperature. The Delta Temperature is used in the code in the following way:

IF ((IndoorTemp - OutdoorTemp) < DeltaTemperature) Then ventilation is not allowed.

Thus, if a large negative number is input for DeltaTemperature, the ventilation can be kept on even if the outdoor temperature is greater than the indoor temperature. This is useful for uncontrolled natural ventilation (open windows) or as a way to estimate the effect of required ventilation air for load calculations.

#### 1.16.6.14 Field: Delta Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the temperature difference (in Celsius) between the indoor and outdoor air dry-bulb temperatures below which ventilation is shutoff as a function of time. The minimum temperature difference value in the schedule can be -100°C. This field is an optional field and has the same functionality as the Delta Temperature field. If the user enters a valid schedule name, the delta temperature values specified in this schedule will override the constant value specified in the Delta Temperature field.

#### 1.16.6.15 Field: Minimum Outdoor Temperature

This is the outdoor temperature (in Celsius) below which ventilation is shut off. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is -100.0°C if the field is left blank. This lower temperature limit is intended to avoid overcooling a space, which could result in a heating load.

#### 1.16.6.16 Field: Minimum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum outdoor temperature (in Celsius) below which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Minimum Outdoor Temperature field. If the user enters a valid schedule name, the temperature values in this schedule will override the constant value specified in the Minimum Outdoor Temperature field.

#### 1.16.6.17 Field: Maximum Outdoor Temperature

This is the outdoor temperature (in Celsius) above which ventilation is shut off. The minimum value for this field is -100.0°C and the maximum value is 100.0°C. The default value is 100.0°C if the field is left blank. This upper temperature limit is intended to avoid overheating a space, which could result in a cooling load.

#### 1.16.6.18 Field: Maximum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum outdoor temperature (in Celsius) above which ventilation is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field and has the same functionality as the Maximum Outdoor Temperature field. If the user enters a valid schedule name, the temperature values in this schedule will override the constant value specified in the Maximum Outdoor Temperature field.

#### 1.16.6.19 Field: Maximum Wind Speed

This is the wind speed (m/s) above which ventilation is shut off. This can help simulate conditions where one would normally close windows to avoid chaos in a space (papers blowing around, etc.).

An IDF example is provided below:

```
ZoneVentilation:WindandStackOpenArea,
  ZONE 3 Vent1 1,      !- Name
  ZONE 3,              !- Zone Name
  0.5,                !- Opening Area {m2}
  Constant,           !- Opening Area Fraction Schedule Name
  AutoCalculate,      !- Opening Effectiveness
  0.0,                !- Effective Angle {deg}
  1.0,                !- Height Difference {m}
  AutoCalculate,      !- Discharge Coefficient for Opening
  18.0,               !- Minimum Indoor Temperature {C}
  ,                   !- Minimum Indoor Temperature Schedule Name
  ,                   !- Maximum Indoor Temperature {C}

```

### 1.16.7 ZoneVentilation Outputs

Current ventilation output variables:

- HVAC,Sum,Zone Ventilation Sensible Heat Loss Energy [J]
- HVAC,Sum,Zone Ventilation Sensible Heat Gain Energy [J]
- HVAC,Sum,Zone Ventilation Latent Heat Loss Energy [J]
- HVAC,Sum,Zone Ventilation Latent Heat Gain Energy [J]
- HVAC,Sum,Zone Ventilation Total Heat Loss Energy [J]
- HVAC,Sum,Zone Ventilation Total Heat Gain Energy [J]
- HVAC,Average,Zone Ventilation Current Density Volume Flow Rate [m3/s]
- HVAC,Average,Zone Ventilation Standard Density Volume Flow Rate [m3/s]
- HVAC,Sum,Zone Ventilation Current Density Volume [m3]
- HVAC,Sum,Zone Ventilation Standard Density Volume [m3]
- HVAC,Sum,Zone Ventilation Mass [kg]
- HVAC,Sum,Zone Ventilation Mass Flow Rate [kg/s]
- HVAC,Average,Zone Ventilation Air Change Rate [ach]
- HVAC,Sum,Zone Ventilation Fan Electric Energy [J]
- HVAC,Average,Zone Ventilation Air Inlet Temperature [C]

Note: If ZoneVentilation:\* objects and ZoneAirBalance:OutdoorAir (with Air Balance Method = Quadrature) objects reference the same Zone Name, the above ventilation output variables will not be reported for that zone. Instead, output variables for zone outdoor air flow will be reported by the corresponding ZoneAirBalance:OutdoorAir object.

#### **1.16.7.1 Zone Ventilation Sensible Heat Loss Energy [J]**

The sensible (temperature) heat loss that occurs when the ventilation inlet air temperature < zone air temperature. If multiple ventilation objects are specified for a particular zone, the ventilation inlet air temperature is from all ZoneVentilation:DesignFlowRate and ZoneVentilation:WindandStackOpenArea objects specified for the zone.

#### **1.16.7.2 Zone Ventilation Sensible Heat Gain Energy [J]**

The sensible (temperature) heat gain that occurs when the ventilation inlet air temperature >= zone air temperature. If multiple ventilation objects are specified for a particular zone, the ventilation inlet air temperature is from all ZoneVentilation:DesignFlowRate and ZoneVentilation:WindandStackOpenArea objects specified for the zone.

#### **1.16.7.3 Zone Ventilation Latent Heat Loss Energy [J]**

The latent heat loss that occurs when the Ventilation air humidity ratio (outdoor) < zone air humidity ratio from all ZoneVentilation:DesignFlowRate and ZoneVentilation:WindandStackOpenArea objects specified for the zone.

#### **1.16.7.4 Zone Ventilation Latent Heat Gain Energy [J]**

The latent heat gain that occurs when the Ventilation air humidity ratio (outdoor) >= zone air humidity ratio from all ZoneVentilation:DesignFlowRate and ZoneVentilation:WindandStackOpenArea objects specified for the zone.

#### **1.16.7.5 Zone Ventilation Total Heat Loss Energy [J]**

The total heat loss that occurs when the sum of Zone Ventilation Sensible Heat Gain Energy and Zone Ventilation Latent Heat Gain Energy < the sum of Zone Ventilation Sensible Heat Loss Energy and Zone Ventilation Latent Heat Loss Energy.

#### **1.16.7.6 Zone Ventilation Total Heat Gain Energy [J]**

The total heat gain that occurs when the sum of Zone Ventilation Sensible Heat Gain Energy and Zone Ventilation Latent Heat Gain Energy >= the sum of Zone Ventilation Sensible Heat Loss Energy and Zone Ventilation Latent Heat Loss Energy.

#### **1.16.7.7 Zone Ventilation Current Density Volume [m3]**

#### **1.16.7.8 Zone Ventilation Current Density Volume Flow Rate [m3/s]**

These outputs are the total volume and volume flow rate of ventilation air based on the current density of zone air.

#### **1.16.7.9 Zone Ventilation Standard Density Volume [m3]**

#### **1.16.7.10 Zone Ventilation Standard Density Volume Flow Rate [m3/s]**

These outputs are the total volume and volume flow rate of ventilation air based on the standard density of air. Standard density in EnergyPlus corresponds to 20°C drybulb, dry air, and nominally adjusted for elevation.

#### **1.16.7.11 Zone Ventilation Mass [kg]**

This output is the total mass flow into a particular zone from outdoors.

#### **1.16.7.12 Zone Ventilation Mass Flow Rate [kg/s]**

This output is the total mass flow rate into a particular zone from outdoors.

#### **1.16.7.13 Zone Ventilation Air Change Rate [ach]**

The volume flow rate of the ventilation air in air changes per hour.

#### **1.16.7.14 Zone Ventilation Fan Electric Energy [J]**

The fan electrical consumption for Intake or Exhaust ventilation types (for ZoneVentilation:DesignFlowRate objects only).

#### **1.16.7.15 Zone Ventilation Air Inlet Temperature [C]**

This is equal to the outdoor air temperature except when INTAKE fan power is included (for ZoneVentilation:DesignFlowRate objects only). When intake fan power is used, then the additional heat due to the fan is added to the outdoor temperature and this will be reported as the inlet air temperature. If multiple ventilation objects are specified for a particular zone, the reported value is the mass flow weighted temperature for the multiple ventilation objects specified for this zone.

### 1.16.8 ZoneAirBalance:OutdoorAir

This model calculates a combined zone outdoor airflow by including interactions between mechanical ventilation, infiltration and duct leakage. It is mainly applied to a single zone (e.g., residential) building. The model combines all outdoor airflows from ZoneInfiltration and ZoneVentilation objects in the same zone. This object also includes the induced outdoor airflows due to unbalanced duct leakage, and unbalanced outdoor airflows introduced by unbalanced airflows from ZoneHVAC:EnergyRecoveryVentilator objects when the exhaust airflow is greater than the supply outdoor airflow. This model is intended for simplified outdoor airflow calculations as opposed to the more detailed outdoor airflow investigations that can be performed with the AirflowNetwork model. The equation used to calculate the combined zone outdoor airflow is:

$$Q = \sqrt{Q_n^2 + Q_{u,v}^2 + Q_{u,l}^2} + Q_{b,v} \quad (34)$$

where,

$Q$  = Combined outdoor airflow with infiltration, balanced and unbalanced outdoor air flows, and unbalanced duct leakage [ $\text{m}^3/\text{s}$ ]

$Q_n$  = Natural infiltration airflow from ZoneInfiltration:\* objects [ $\text{m}^3/\text{s}$ ]

$Q_{b,v}$  = Balanced ventilation airflow, excluding infiltration [ $\text{m}^3/\text{s}$ ]

$Q_{u,v}$  = Unbalanced ventilation airflow, excluding infiltration [ $\text{m}^3/\text{s}$ ]

$Q_{u,l}$  = Unbalanced duct leakage: the difference between supply and return leaks [ $\text{m}^3/\text{s}$ ]

This object cannot be used simultaneously with the EnergyPlus AirflowNetwork model. If the AirflowNetwork model is active for a simulation time step, the Air Balance Method is reset to "None" for that time step. More advanced outdoor airflow calculations are possible using the EnergyPlus AirflowNetwork model.

This object does not combine any airflows from Fan:ZoneExhaust objects and is independent of HVAC equipment operation.

This object will not work with the AvailabilityManager:HybridVentilation object in the same zone, when the Simple Airflow Control Type Schedule Name is provided in the HybridVentilation object. For this case, the Air Balance Method is reset to "None".

#### 1.16.8.1 Field: Name

The name of the ZoneOutdoorAir:Combined object.

#### 1.16.8.2 Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a combined outdoor airflow statement to a thermal zone in the building.

#### 1.16.8.3 Field: Air Balance Method

This choice field determines the air balance method. Two choices are Quadrature and None. If Quadrature, the combined zone outdoor air flow is calculated based on the above equation. If None, no combining of outdoor air will be performed (i.e., any ZoneInfiltration:\* and ZoneVentilation:\* objects specified for this zone are simulated individually).

#### 1.16.8.4 Field: Induced Outdoor Air Due to Unbalanced Duct Leakage

This is the induced outdoor airflow rate, in  $\text{m}^3/\text{s}$ , due to unbalanced duct leakage. If left blank, the default value is 0.

#### 1.16.8.5 Field: Induced Outdoor Air Schedule Name

This field is the name of the schedule (ref: Schedule) which modifies the induced outdoor airflow rate value (see previous field). The schedule values must be any positive number between 0 and 1 as a fraction. The actual induced outdoor airflow rate in a zone for a particular simulation time step is defined as the product of the Induced Outdoor Air Due to Unbalanced Duct Leakage input field and the value specified by the schedule named in this input field.

Note: Since this object is independent of HVAC operation, the inputs for the last two fields should be carefully selected to match HVAC system operation schedules.

An IDF example is provided below:

```
ZoneAirBalance:OutdoorAir,
  ZONE 2 Balance 1,      !- Name
  ZONE 2,                !- Zone Name
  Quadrature,           !- Air Balance Method
```

0.00, !- Induced Outdoor Air Due to Unbalanced Duct Leakage {m3/s}  
Constant; !- Induced Outdoor Air Schedule Name

### 1.16.9 ZoneAirBalance:OutdoorAir Outputs

ZoneAirBalance:OutdoorAir output variables will be provided when the Air Balance Method is Quadrature. Output variables from the associated ZoneVentilation:\* and ZoneInfiltration:\* objects for the same zone will not be produced when ZoneAirBalance:OutdoorAir output variables are available. If the Air Balance Method = None, then no ZoneAirBalance:OutputAir outputs will be produced and the associated ZoneVentilation:\* and ZoneInfiltration:\* objects will specify their output variables for the zone.

- HVAC,Sum,Zone Combined Outdoor Air Sensible Heat Loss Energy [J]
- HVAC,Sum,Zone Combined Outdoor Air Sensible Heat Gain Energy [J]
- HVAC,Sum,Zone Combined Outdoor Air Latent Heat Loss Energy [J]
- HVAC,Sum,Zone Combined Outdoor Air Latent Heat Gain Energy [J]
- HVAC,Sum,Zone Combined Outdoor Air Total Heat Loss Energy [J]
- HVAC,Sum,Zone Combined Outdoor Air Total Heat Gain Energy [J]
- HVAC,Average,Zone Combined Outdoor Air Current Density Volume Flow Rate [m3/s]
- HVAC,Average,Zone Combined Outdoor Air Standard Density Volume Flow Rate [m3/s]
- HVAC,Sum,Zone Combined Outdoor Air Current Density Volume [m3]
- HVAC,Sum,Zone Combined Outdoor Air Standard Density Volume [m3]
- HVAC,Sum,Zone Combined Outdoor Air Mass [kg]
- HVAC,Sum,Zone Combined Outdoor Air Mass Flow Rate [kg/s]
- HVAC,Average, Zone Combined Outdoor Air Changes per Hour [ach]
- HVAC,Sum, Zone Combined Outdoor Air Fan Electric Energy [J]

#### 1.16.9.1 Zone Combined Outdoor Air Sensible Heat Loss Energy [J]

The sensible (temperature) heat loss that occurs when the outdoor air temperature < zone air temperature.

#### 1.16.9.2 Zone Combined Outdoor Air Sensible Heat Gain Energy [J]

The sensible (temperature) heat gain that occurs when the outdoor air temperature >= zone air temperature.

#### 1.16.9.3 Zone Combined Outdoor Air Latent Heat Loss Energy [J]

The latent heat loss that occurs when the outdoor air humidity ratio < zone air humidity ratio.

#### 1.16.9.4 Zone Combined Outdoor Air Latent Heat Gain Energy [J]

The latent heat gain that occurs when the outdoor air humidity ratio >= zone air humidity ratio.

#### 1.16.9.5 Zone Combined Outdoor Air Total Heat Loss Energy [J]

The total heat loss that occurs when the sum of Zone Combined Outdoor Air Sensible Heat Gain Energy and Zone Combined Outdoor Air Latent Heat Gain Energy < the sum of Zone Combined Outdoor Air Sensible Heat Loss Energy and Zone Combined Outdoor Air Latent Heat Loss Energy.

#### 1.16.9.6 Zone Combined Outdoor Air Total Heat Gain Energy [J]

The total heat gain that occurs when the sum of Zone Combined Outdoor Air Sensible Heat Gain Energy and Zone Combined Outdoor Air Latent Heat Gain Energy >= the sum of Zone Combined Outdoor Air Sensible Heat Loss Energy and Zone Combined Outdoor Air Latent Heat Loss Energy.

#### 1.16.9.7 Zone Combined Outdoor Air Current Density Volume [m3]

#### 1.16.9.8 Zone Combined Outdoor Air Current Density Volume Flow Rate [m3/s]

These outputs are the total volume and volume flow rate of outdoor air based on the current density of zone air.

#### 1.16.9.9 Zone Combined Outdoor Air Standard Density Volume [m3]

#### **1.16.9.10 Zone Combined Outdoor Air Standard Density Volume Flow Rate [m3/s]**

These outputs are the total volume and volume flow rate of outdoor air based on the standard density of air. Standard density in EnergyPlus corresponds to 20°C drybulb, dry air, and nominally adjusted for elevation.

#### **1.16.9.11 Zone Combined Outdoor Air Mass [kg]**

This output is the total mass flow into a particular zone from outdoors.

#### **1.16.9.12 Zone Combined Outdoor Air Mass Flow Rate [kg/s]**

This output is the total mass flow rate into a particular zone from outdoors.

#### **1.16.9.13 Zone Combined Outdoor Air Changes per Hour [ach]**

The volume flow rate of the ventilation air in air changes per hour.

#### **1.16.9.14 Zone Combined Outdoor Air Fan Electric Energy [J]**

The fan electrical consumption for Intake, Exhaust, or Balanced ventilation types (for ZoneVentilation:DesignFlowRate objects used to calculate a combined zone outdoor airflow).

### **1.16.10 ZoneMixing**

In EnergyPlus, the ZoneMixing syntax is intended to allow simplified treatment of air exchange between zones. Note that this statement only affects the energy balance of the “receiving” zone and that this statement will not produce any effect on the “source” zone. Mixing statements can be complementary and include multiple zones, but the balancing of flows between zones is left to the user’s discretion. The use of the Cross Mixing syntax (ref: Cross Mixing) can allow for automatic balancing of flows and energy flow rates between zones but is hindered by the limitation of only a single cross mixing statement per zone. The use of Refrigeration Door Mixing syntax (ref: Refrigeration Door Mixing) automatically balances the flow and energy between two zones and allows multiple mixing statements per zone. More advanced mixing calculations are possible using the EnergyPlus AirflowNetwork model for multi-zone airflow with or without HVAC system operation. Mixing is entered using the following syntax.

#### **1.16.10.1 Field: Name**

The name of the ZoneMixing object.

#### **1.16.10.2 Field: Zone Name**

This field is the name of the zone (ref: Zone) receiving the amount of air being exchanged and attaches a particular mixing statement to a thermal zone in the building.

#### **1.16.10.3 Field: Schedule Name**

This field is the name of the schedule (ref: Schedule) that modifies the maximum design volume flow rate parameter (see next field). This fraction between 0.0 and 1.0 modifies the design level parameter.

#### **1.16.10.4 Field: Design Flow Rate Calculation Method**

This field is a key/choice field that tells which of the next four fields are filled and is descriptive of the method for calculating the design volume flow rate. The key/choices are:

- Flow/Zone

With this choice, the method used will be a straight insertion of the design volume flow rate. (The Design Flow Rate field should be filled.)

- Flow/Area

With this choice, the method used will be a factor per floor area of the zone. (The Flow per Zone Floor Area field should be filled.)

- Flow/Person

With this choice, the method used will be a factor per nominal number of people in the zone. (The Flow per Person field should be filled.)

- AirChanges/Hour

With this choice, the method used will be the number of air changes per hour for the infiltration amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. (The Air Changes per Hour field should be filled.)

#### 1.16.10.5 Field: Design Flow Rate

This field denotes the full design volume flow rate ( $m^3/s$ ). The previous field should choose “flow/zone” as the choice. The design volume flow rate is the maximum amount of mixing air expected. The design value is modified by the schedule fraction (see Field: Schedule Name) and user specified coefficients (see four “coefficient” fields below).

#### 1.16.10.6 Field: Flow Rate per Zone Floor Area

This factor ( $m^3/s-m^2$ ) is used, along with the Zone Area to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “Flow/Area”.

#### 1.16.10.7 Field: Flow Rate per Person

This factor ( $m^3/s-person$ ) is used, along with the nominal (maximum) number of occupants (people) in the Zone to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “Flow/Person”.

#### 1.16.10.8 Field: Air Changes per Hour

With this choice, the method used will be the number of air changes per hour for the mixing amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. The choice from the method field should be “AirChanges/Hour”.

#### 1.16.10.9 Field: Source Zone Name

This field is the name of the “source” zone (ref: Zone) that exhausts the amount of air specified by the design level and schedule fields to the zone named in the zone name field.

#### 1.16.10.10 Field: Delta Temperature

This number controls when mixing air from the source zone is sent to the receiving zone. This parameter is a temperature and is expressed in units of Celsius. If this field is positive, the temperature of the zone from which the air is being drawn (source zone) must be “Delta Temperature” warmer than the receiving zone air or else no mixing occurs. If this field is negative, the temperature of the source zone must be “Delta Temperature” cooler than the receiving zone air or else no mixing occurs. If this parameter is zero, mixing occurs regardless of the relative zone temperatures.

#### 1.16.10.11 Field: Delta Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the temperature difference (in Celsius) between the source zone and receiving zone air dry-bulb temperatures as a function of time. This field is an optional field and has the same functionality as the Delta Temperature field. If the user enters a valid schedule name, the delta temperature values specified in this schedule will supersede the constant value specified in the Delta Temperature field.

#### 1.16.10.12 Field: Minimum Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum receiving zone temperature (in Celsius) below which mixing is shutoff as a function of time. The minimum temperature value in the schedule can be  $-100^{\circ}C$  and the maximum value can be  $100^{\circ}C$ . This field is an optional field. If this field is not entered, the minimum zone temperature control is not applied.

#### 1.16.10.13 Field: Maximum Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the maximum receiving zone temperature (in Celsius) above which mixing is shutoff as a function of time. The maximum temperature value in the schedule can be  $-100^{\circ}C$  and the maximum value can be  $100^{\circ}C$ . This field is an optional field. If this field is not entered, the maximum zone temperature control is not applied.

**Note:** The maximum zone temperature when mixing is shutoff must be greater than or equal to the minimum zone temperature when mixing is shutoff at any given time. Otherwise, warnings will be issued and the maximum zone shutoff temperature will be set to the minimum zone shutoff temperature.

#### 1.16.10.14 Field: Minimum Source Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum source zone temperature (in Celsius) below which mixing is shutoff as a function of time. The minimum temperature value in the schedule can be  $-100^{\circ}C$  and the maximum value can be  $100^{\circ}C$ . This field is an optional field. If this field is not entered, the minimum source zone temperature control is not applied.

#### 1.16.10.15 Field: Maximum Source Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the maximum source zone temperature (in Celsius) above which mixing is shutoff as a function of time. The maximum temperature value in the schedule can be  $-100^{\circ}C$  and the maximum value can be  $100^{\circ}C$ . This field is an optional field. If this field is not entered, the maximum source zone temperature control is not applied.

**Note:** The maximum source zone temperature when mixing is shutoff must be greater than or equal to the minimum source zone temperature when mixing is shutoff at any given time. Otherwise, warnings will be issued and the maximum source zone shutoff temperature will be set to the minimum source zone shutoff temperature.

#### 1.16.10.16 Field: Minimum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum outdoor temperature (in Celsius) below which mixing is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the minimum outdoor temperature control is not applied.

#### 1.16.10.17 Field: Maximum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the maximum outdoor temperature (in Celsius) above which mixing is shutoff as a function of time. The maximum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the maximum outdoor temperature control is not applied.

**Note:** The maximum outdoor temperature when mixing is shutoff must be greater than or equal to the minimum outdoor temperature which mixing is shutoff at any given time. Otherwise, a warning will be issued and the maximum outdoor shutoff temperature will be set to the minimum outdoor shutoff temperature.

#### 1.16.11.1 Zone Mixing Volume [m3]

The air volume in m<sup>3</sup> entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep.

#### 1.16.11.2 Zone Mixing Current Density Volumetric Flow Rate [m3/s]

The air volumetric flow rate in m<sup>3</sup>/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep using the density of air evaluated at current zone air conditions.

#### 1.16.11.3 Zone Mixing Standard Density Volumetric Flow Rate [m3/s]

The air volumetric flow rate in m<sup>3</sup>/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep using the density of air evaluated at standard conditions.

#### 1.16.11.4 Zone Mixing Mass [kg]

The air mass in kg entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep. The air mass is calculated using the air volume flow from each "source" zone and the density of air calculated for the average conditions (temperature and humidity) between the "source" and "receiving" zones.

#### **1.16.11.5 Zone Mixing Mass Flow Rate [kg/s]**

The air mass flow rate in kg/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep.

#### **1.16.11.6 Zone Mixing Sensible Heat Loss Energy [J]**

#### **1.16.11.7 Zone Mixing Sensible Heat Gain Energy [J]**

The sensible (temperature) heat transfer due to the sum of mixing, cross-mixing, and refrigeration-door mixing in the host (receiving) zone is the sum of all the incoming air mass flow rates multiplied by the elapsed time, the specific heat (calculated for the average conditions (temperature and humidity) between the "source" and "receiving" zones) and the temperature differences between the host zone and corresponding source zones. If the heat transfer is negative, the heat transfer is considered to be a zone mixing sensible heat loss. If the heat transfer is positive, the heat transfer is considered to be a zone mixing sensible heat gain.

#### **1.16.11.8 Zone Mixing Latent Heat Loss Energy [J]**

#### **1.16.11.9 Zone Mixing Latent Heat Gain Energy [J]**

The latent heat transfer due to the sum of mixing, cross-mixing, and refrigeration-door mixing in the host (receiving) zone is the sum of all the incoming air mass flow rates multiplied by the elapsed time, the heat of vaporization (calculated for the average conditions (temperature and humidity) between the "source" and "receiving" zones) and the humidity ratio differences between the host zone and corresponding source zones. If the heat transfer is negative, the heat transfer is considered to be a zone mixing latent heat loss. If the heat transfer is positive, the heat transfer is considered to be a zone mixing latent heat gain.

#### **1.16.11.10 Zone Mixing Total Heat Loss Energy [J]**

The total heat loss due to the sum of mixing, cross-mixing, and refrigeration-door mixing that occurs when the sum of Zone Mixing Sensible Heat Gain Energy and Zone Mixing Latent Heat Gain Energy < the sum of Zone Mixing Sensible Heat Loss Energy and Zone Mixing Latent Heat Loss Energy.

#### **1.16.11.11 Zone Mixing Total Heat Gain Energy [J]**

The total heat gain due to the sum of mixing, cross-mixing, and refrigeration-door mixing that occurs when the sum of Zone Mixing Sensible Heat Gain Energy and Zone Mixing Latent Heat Gain Energy >= the sum of Zone Mixing Sensible Heat Loss Energy and Zone Mixing Latent Heat Loss Energy.

### **1.16.12 ZoneCrossMixing**

The ZoneCrossMixing syntax is ideally suited for two zones that exchange an equal amount of air between each other and do not have any air exchange with other zones. As with Mixing (ref: Mixing), this is a simplified view of interzone airflow in EnergyPlus. The main difference between Mixing and Cross Mixing is that Cross Mixing has an energy effect on both the source and the receiving zone, thus maintaining both the air mass and energy balances in the two zones.

Cross Mixing can be entered once, in one of the mixing zones; or twice, once for each zone. The object should be entered once if Delta Temperature > 0.0 and it is desirable to have mixing only when the source zone is warmer than the receiving zone. This might be the case when the warmer zone is below the colder zone and the mixing is buoyancy driven. If the zones are next to each other, separated by an open doorway, it would be more suitable to input a cross mixing object for each zone. Then mixing would occur if the zone temperatures differed by Delta Temperature or greater regardless of which is the warmer zone.

If Delta Temperature = 0.0, Cross Mixing can be entered either once or twice: the effect is exactly the same.

Cross Mixing is entered using the following syntax.

#### **1.16.12.1 Field: Name**

The name of the ZoneCrossMixing object.

#### **1.16.12.2 Field: Zone Name**

This field is the name of the zone (ref: Zone) receiving the amount of air being exchanged and attaches a particular cross mixing statement to a thermal zone in the building.

#### **1.16.12.3 Field: Schedule Name**

This field is the name of the schedule (ref: Schedule) that modifies the maximum design volume flow rate parameter (see next field). This fraction between 0.0 and 1.0 modifies the design level parameter.

#### **1.16.12.4 Field: Design Flow Rate Calculation Method**

This field is a key/choice field that tells which of the next four fields are filled and is descriptive of the method for calculating the design volume flow rate. The key/choices are:

- Flow/Zone

With this choice, the method used will be a straight insertion of the design volume flow rate. (The Design Flow Rate field should be filled.)

- Flow/Area

With this choice, the method used will be a factor per floor area of the zone. (The Flow per Zone Floor Area field should be filled).

- Flow/Person

With this choice, the method used will be a factor per nominal number of people in the zone. (The flow per person field should be filled).

- AirChanges/Hour

With this choice, the method used will be the number of air changes per hour for the infiltration amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. (The Air Changes per Hour field should be filled).

#### **1.16.12.5 Field: Design Flow Rate**

This field denotes the full design volume flow rate ( $\text{m}^3/\text{s}$ ). The previous field should choose “flow/zone” as the choice. The design volume flow rate is the maximum amount of mixing air expected. The design value is modified by the schedule fraction (see Field: Schedule Name) and user specified coefficients (see four “coefficient” fields below).

#### **1.16.12.6 Field: Flow Rate per Zone Floor Area**

This factor ( $\text{m}^3/\text{s}\cdot\text{m}^2$ ) is used, along with the Zone Area to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “Flow/Area”.

#### **1.16.12.7 Field: Flow Rate per Person**

This factor ( $\text{m}^3/\text{s}\cdot\text{person}$ ) is used, along with the nominal (maximum) number of occupants (people) in the Zone to determine the maximum Design Volume Flow Rate as described in the Design Volume Flow Rate field. The choice from the method field should be “Flow/Person”.

#### **1.16.12.8 Field: Air Changes per Hour**

With this choice, the method used will be the number of air changes per hour for the mixing amount. This factor, along with the Zone Volume, will be used to determine the Design Flow Rate. The choice from the method field should be “AirChanges/Hour”.

#### **1.16.12.9 Field: Source Zone Name**

This field is the name of the “source” zone (ref: Zone) that exhausts the amount of air specified by the design level and schedule fields to the zone named in the zone name field. In reality, the “source” and “receiving” zones are interchangeable since the cross-mixed air affects both zones.

#### **1.16.12.10 Field: Delta Temperature**

This number controls when mixing air from the source zone is sent to the receiving zone. This parameter is a temperature and is expressed in units of Celsius. If this field is positive, the temperature of the zone from which air is being drawn (“source zone”) must be “Delta Temperature” warmer than the zone air or no mixing occurs. If this field is zero, mixing occurs regardless of the relative air temperatures. Negative values for “Delta Temperature” are not permitted.

#### **1.16.12.11 Field: Delta Temperature Schedule Name**

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the temperature difference (in Celsius) between the source zone and receiving zone air dry-bulb temperatures as a function of time. This field is an optional field and has the same functionality as the Delta Temperature field. If the user enters a valid schedule name, the delta temperature values specified in this schedule will supersede the constant value specified in the Delta Temperature field.

#### **1.16.12.12 Field: Minimum Zone Temperature Schedule Name**

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum receiving zone temperature (in Celsius) below which cross mixing is shutoff as a function of time. The minimum temperature value in the schedule can be  $-100^\circ\text{C}$  and the maximum value can be  $100^\circ\text{C}$ . This field is an optional field. If this field is not entered, the minimum zone temperature control is not applied.

#### **1.16.12.13 Field: Maximum Zone Temperature Schedule Name**

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the maximum receiving zone temperature (in Celsius) above which cross

mixing is shutoff as a function of time. The maximum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the maximum zone temperature control is not applied.

**Note:** The maximum zone temperature when cross mixing is shutoff must be greater than or equal to the minimum zone temperature when cross mixing is shutoff at any given time. Otherwise, warnings will be issued and the maximum zone shutoff temperature will be set to the minimum zone shutoff temperature.

#### 1.16.12.14 Field: Minimum Source Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum source zone temperature (in Celsius) below which cross mixing is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the minimum source zone temperature control is not applied.

#### 1.16.12.15 Field: Maximum Source Zone Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the maximum source zone temperature (in Celsius) above which cross mixing is shutoff as a function of time. The maximum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the maximum source zone temperature control is not applied.

**Note:** The maximum source zone temperature when cross mixing is shutoff must be greater than or equal to the minimum source zone temperature when cross mixing is shutoff at any given time. Otherwise, warnings will be issued and the maximum source zone shutoff temperature will be set to the minimum source zone shutoff temperature.

#### 1.16.12.16 Field: Minimum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the minimum outdoor temperature (in Celsius) below which cross mixing is shutoff as a function of time. The minimum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the minimum outdoor temperature control is not applied.

#### 1.16.12.17 Field: Maximum Outdoor Temperature Schedule Name

This alpha field contains the name of a schedule (ref. Schedule objects) which contains the maximum outdoor temperature (in Celsius) above which cross mixing is shutoff as a function of time. The maximum temperature value in the schedule can be -100°C and the maximum value can be 100°C. This field is an optional field. If this field is not entered, the maximum outdoor temperature control is not applied.

**Note:** The maximum outdoor temperature when cross mixing is shutoff must be greater than or equal to the minimum outdoor temperature which cross mixing is shutoff at any given time. Otherwise, a warning will be issued and the maximum outdoor shutoff temperature will be set to the minimum outdoor shutoff temperature.

- HVAC,Sum,Zone Mixing Total Heat Gain Energy [J]

#### **1.16.13.1 Zone Mixing Volume [m<sup>3</sup>]**

The air volume in m<sup>3</sup> entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep.

#### **1.16.13.2 Zone Mixing Current Density Volumetric Flow Rate [m<sup>3</sup>/s]**

The air volumetric flow rate in m<sup>3</sup>/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep using the density of air evaluated at current zone air conditions.

#### **1.16.13.3 Zone Mixing Standard Density Volumetric Flow Rate [m<sup>3</sup>/s]**

The air volumetric flow rate in m<sup>3</sup>/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep using the density of air evaluated at standard conditions.

#### **1.16.13.4 Zone Mixing Mass [kg]**

The air mass in kg entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep. The air mass is calculated using the air volume flow from each “source” zone and the density of air calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones.

#### **1.16.13.5 Zone Mixing Mass Flow Rate [kg/s]**

The air mass flow rate in kg/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep.

#### **1.16.13.6 Zone Mixing Sensible Heat Loss Energy [J]**

#### **1.16.13.7 Zone Mixing Sensible Heat Gain Energy [J]**

The sensible (temperature) heat transfer due to the sum of mixing, cross-mixing, and refrigeration-door mixing in the host (receiving) zone is the sum of all the incoming air mass flow rates multiplied by the elapsed time, the specific heat (calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones) and the temperature differences between the host zone and corresponding source zones. If the heat transfer is negative, the heat transfer is considered to be a zone mixing sensible heat loss. If the heat transfer is positive, the heat transfer is considered to be a zone mixing sensible heat gain.

#### **1.16.13.8 Zone Mixing Latent Heat Loss Energy [J]**

#### **1.16.13.9 Zone Mixing Latent Heat Gain Energy [J]**

The latent heat transfer due to the sum of mixing, cross-mixing, and refrigeration-door mixing in the host (receiving) zone is the sum of all the incoming air mass flow rates multiplied by the elapsed time, the heat of vaporization (calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones) and the humidity ratio differences between the host zone and corresponding source zones. If the heat transfer is negative, the heat transfer is considered to be a zone mixing latent heat loss. If the heat transfer is positive, the heat transfer is considered to be a zone mixing latent heat gain.

#### **1.16.13.10 Zone Mixing Total Heat Loss Energy [J]**

The total heat loss due to the sum of mixing, cross-mixing, and refrigeration-door mixing that occurs when the sum of Zone Mixing Sensible Heat Gain Energy and Zone Mixing Latent Heat Gain Energy < the sum of Zone Mixing Sensible Heat Loss Energy and Zone Mixing Latent Heat Loss Energy.

#### **1.16.13.11 Zone Mixing Total Heat Gain Energy [J]**

The total heat gain due to the sum of mixing, cross-mixing, and refrigeration-door mixing that occurs when the sum of Zone Mixing Sensible Heat Gain Energy and Zone Mixing Latent Heat Gain Energy >= the sum of Zone Mixing Sensible Heat Loss Energy and Zone Mixing Latent Heat Loss Energy.

## 1.16.14 ZoneRefrigerationDoorMixing

The ZoneRefrigerationDoorMixing syntax is ideally suited for two zones, at least one of which is refrigerated, that exchange an equal amount of dry air. They may also have mixed air from other zones, but only one object should be entered for any one pair of zones. As with Mixing (ref: Mixing), this is a simplified view of interzone airflow in EnergyPlus. The ZoneRefrigerationDoorMixing approach shares some features of both Mixing and Cross Mixing. Like Cross Mixing, RefrigerationDoorMixing has an energy effect on both the source and the receiving zone, thus maintaining both the air mass and energy balances in the two zones. Like Mixing, the refrigerated zone can exchange air with multiple zones. Unlike either of the other two mixing objects, the RefrigeratedDoorMixing always calculates the air exchange based on the zone temperature and relative humidity. That is, the user does not specify the air flow rate. The user can moderate the flow through a door-opening schedule.

Unlike, Cross Mixing, Refrigeration Door Mixing can only be entered once for any unique pair of zones. It doesn't matter which zone is listed first and the zones will automatically switch back and forth between source and receiving zones depending upon which zone is colder.

Refrigeration Door Mixing is entered using the following syntax.

### 1.16.14.1 Field: Name

The name of the ZoneRefrigerationDoorMixing object.

### 1.16.14.2 Field: Zone 1 Name

This field is the name of one of the two zones (ref: Zone) exchanging air and attaches a particular refrigeration door mixing statement to both thermal zones in the building.

### 1.16.14.3 Field: Zone 2 Name

This field is the name of the other zone (ref: Zone) exchanging air and attaches a particular refrigeration door mixing statement to both thermal zones in the building.

### 1.16.14.4 Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the door opening between the two zones and should contain values between 0.0 and 1.0.

### 1.16.14.5 Field: Door Height

This field denotes the door opening height (m). The default value is 3 m.

### 1.16.14.6 Field: Door Area

This field denotes the door opening area (m<sup>2</sup>). The default value is 9 m<sup>2</sup>.

### 1.16.14.7 Field: Door Protection Type

This field is a key/choice field that tells how the door is protected. The impact of this choice is described in the Engineering Reference. The key/choices are:

- None

None, or no door protection is the default choice

- AirCurtain
- StripCurtain

An IDF Example:

```
ZoneRefrigerationDoorMixing,  
  Freezer1_Cooler1,  !- Name  
  Freezer1,         !- Zone 1 Name  
  Cooler1,         !- Zone 2 Name  
  Freezer1DoorSched, !- Schedule Name  
  1.8,             !- Door height {m}  
  2.3,             !- Door area {m2}  
  StripCurtain;    !- Door protection type
```

## 1.16.15 Refrigeration Door Mixing Outputs

- HVAC,Sum,Zone Mixing Volume [m3]
- HVAC,Sum,Zone Mixing Current Density Volumetric Flow Rate [m3/s]
- HVAC,Sum,Zone Mixing Standard Density Volumetric Flow Rate [m3/s]

- HVAC,Sum,Zone Mixing Mass [kg]
- HVAC,Sum,Zone Mixing Mass Flow Rate [kg/s]
- HVAC,Sum,Zone Mixing Sensible Heat Loss Energy [J]
- HVAC,Sum,Zone Mixing Sensible Heat Gain Energy [J]
- HVAC,Sum,Zone Mixing Latent Heat Loss Energy [J]
- HVAC,Sum,Zone Mixing Latent Heat Gain Energy [J]
- HVAC,Sum,Zone Mixing Total Heat Loss Energy [J]
- HVAC,Sum,Zone Mixing Total Heat Gain Energy [J]

#### **1.16.15.1 Zone Mixing Volume [m<sup>3</sup>]**

The air volume in m<sup>3</sup> entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep.

#### **1.16.15.2 Zone Mixing Current Density Volumetric Flow Rate [m<sup>3</sup>/s]**

The air volumetric flow rate in m<sup>3</sup>/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep using the density of air evaluated at current zone air conditions.

#### **1.16.15.3 Zone Mixing Standard Density Volumetric Flow Rate [m<sup>3</sup>/s]**

The air volumetric flow rate in m<sup>3</sup>/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep using the density of air evaluated at standard conditions.

#### **1.16.15.4 Zone Mixing Mass [kg]**

The air mass in kg entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep. The air mass is calculated using the air volume flow from each “source” zone and the density of air calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones.

#### **1.16.15.5 Zone Mixing Mass Flow Rate [kg/s]**

The air mass flow rate in kg/s entering the zone due to the sum of mixing, cross-mixing, and refrigeration-door mixing during the hour or timestep.

#### **1.16.15.6 Zone Mixing Sensible Heat Loss Energy [J]**

#### **1.16.15.7 Zone Mixing Sensible Heat Gain Energy [J]**

The sensible (temperature) heat transfer due to the sum of mixing, cross-mixing, and refrigeration-door mixing in the host (receiving) zone is the sum of all the incoming air mass flow rates multiplied by the elapsed time, the specific heat (calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones) and the temperature differences between the host zone and corresponding source zones. If the heat transfer is negative, the heat transfer is considered to be a zone mixing sensible heat loss. If the heat transfer is positive, the heat transfer is considered to be a zone mixing sensible heat gain.

#### **1.16.15.8 Zone Mixing Latent Heat Loss Energy [J]**

#### **1.16.15.9 Zone Mixing Latent Heat Gain Energy [J]**

The latent heat transfer due to the sum of mixing, cross-mixing, and refrigeration-door mixing in the host (receiving) zone is the sum of all the incoming air mass flow rates multiplied by the elapsed time, the heat of vaporization (calculated for the average conditions (temperature and humidity) between the “source” and “receiving” zones) and the humidity ratio differences between the host zone and corresponding source zones. If the heat transfer is negative, the heat transfer is considered to be a zone mixing latent heat loss. If the heat transfer is positive, the heat transfer is considered to be a zone mixing latent heat gain.

#### **1.16.15.10 Zone Mixing Total Heat Loss Energy [J]**

The total heat loss due to the sum of mixing, cross-mixing, and refrigeration-door mixing that occurs when the sum of Zone Mixing Sensible Heat Gain Energy and Zone Mixing Latent Heat Gain Energy < the sum of Zone Mixing Sensible Heat Loss Energy and Zone Mixing Latent Heat Loss Energy.

#### **1.16.15.11 Zone Mixing Total Heat Gain Energy [J]**

The total heat gain due to the sum of mixing, cross-mixing, and refrigeration-door mixing that occurs when the sum of Zone Mixing Sensible Heat Gain Energy and Zone Mixing Latent Heat Gain Energy >= the sum of Zone Mixing Sensible Heat Loss Energy and Zone Mixing Latent Heat Loss Energy.

## 1.16.16 ZoneEarthtube (Earth Tube)

An earth tube is a long, underground metal or plastic pipe through which air is drawn. During cooling season, as air travels through the pipe, it gives up some of its heat to the surrounding soil and enters the room as cooler air. Similarly, during heating season, as air travels through the pipe, it receives some of its heat from the soil and enters the room as warmer air. Simple earth tubes in EnergyPlus can be controlled by a schedule and through the specification of minimum, maximum, and delta temperatures as described below. As with infiltration and ventilation, the actual flow rate of air through the earth tube can be modified by the temperature difference between the inside and outside environment and the wind speed. The basic equation used to calculate air flow rate of earth tube in EnergyPlus is:

$$EarthTubeFlowRate = (E_{design})(F_{schedule}) [A + B|T_{zone} - T_{odb}| + C(WindSpeed) + D(WindSpeed^2)] \quad (35)$$

For the simulation of the earth tube, a weather data file is required and, therefore, the earth tube cannot run without weather data file. The required input fields to simulate the earth tube include the average soil surface temperature, the amplitude of soil surface temperature, and the phase constant of soil surface temperature. These fields should be calculated in advance by using a separate stand-alone program (CalcSoilSurfTemp) and should be input into earth tube.

### 1.16.16.1 CalcSoilSurfTemp – Auxiliary Programs Document

The CalcSoilSurfTemp program is simple and requires only two input fields : soil condition and soil surface condition in addition to a valid weather file. For soil condition, the user should select the number corresponding to the actual condition of the soil surrounding the earth tube from the four following options: 1. HEAVY AND SATURATED, 2. HEAVY AND DAMP, 3. HEAVY AND DRY and 4. LIGHT AND DRY. This determines the thermal diffusivity and thermal conductivity of the surrounding soil. For soil surface conditions, the user should select the number corresponding to the actual condition of the ground surface above the earth tube from the eight following options: 1. BARE AND WET, 2. BARE AND MOIST, 3. BARE AND ARID, 4. BARE AND DRY, 5. COVERED AND WET, 6. COVERED AND MOIST, 7. COVERED AND ARID and 8. COVERED AND DRY. This determines the absorption coefficient and the fraction of evaporation rate of the ground surface.

From this information and an analysis of the weather for the location selected, the CalcSoilSurfTemp program (ref. Auxiliary Programs document) calculates the three parameters listed above. The user must then add these parameters as input into EnergyPlus. The full input description of an earth tube in EnergyPlus is given below.

### 1.16.16.2 Field: Zone Name

This field is the name of the zone (ref: Zone) and attaches a particular earth tube statement to a thermal zone in the building.

### 1.16.16.3 Field: Schedule Name

This field is the name of the schedule (ref: Schedule) that modifies the maximum design volume flow rate parameter (see next field). This fraction between 0.0 and 1.0 is noted as  $F_{schedule}$  in the above equation.

### 1.16.16.4 Field: Design Flow Rate

This number (noted as  $E_{design}$  in the above equation) is the maximum amount of air mass flow rate of the earth tube expected at design conditions. The flow rate is expressed in units of  $m^3/s$ . The design value is modified by the schedule fraction (see previous field) and user specified coefficients (see last four fields).

### 1.16.16.5 Field: Minimum Zone Temperature when Cooling

This is the indoor temperature (in Celsius) below which the earth tube is shut off. This lower temperature limit is intended to avoid overcooling a space and thus result in a heating load. For example, if the user specifies a minimum temperature of 20°C, earth tube is assumed to be available if the zone air temperature is above 20°C. If the zone air temperature drops below 20°C, then earth tube is automatically turned off.

### 1.16.16.6 Field: Maximum Zone Temperature when Heating

This is the indoor temperature (in Celsius) above which the earth tube is shut off. This higher temperature limit is intended to avoid overheating a space and thus result in a cooling load. For example, if the user specifies a maximum temperature of 20°C, earth tube is assumed to be available if the zone air temperature is below 20°C. If the zone air temperature rises above 20°C, then earth tube is automatically turned off.

### 1.16.16.7 Field: Delta Temperature

This is the temperature difference (in Celsius) between the indoor and outdoor air dry-bulb temperatures below which the earth tube is shut off. This is to allow the earth tube to be stopped either if the temperature outside is too warm and could potentially heat the space or if the temperature outside is too cold and could potentially cool the space. For example, if the user specifies a delta temperature of 2°C, earth tube is assumed to be available if the temperature difference between indoor and outdoor temperature is at least 2°C. If the outside air dry-bulb temperature is less than 2°C cooler or warmer than the indoor dry-bulb temperature, then the earth tube is automatically turned off.

### 1.16.16.8 Field: Earthtube Type

This alpha character string defines the type of earth tube as one of the following options: Natural, Exhaust, or Intake. A natural earth tube is assumed to be air

movement/exchange that will not consume any fan energy or is the result of natural air flow through the tube and into the building. Values for fan pressure and efficiency for a natural flow earth tube are ignored. For either EXHAUST or Intake, values for fan pressure and efficiency define the fan electric consumption. For Natural and Exhaust earth tubes, the conditions of the air entering the space are assumed to be equivalent to the air which is cooled or heated by passing along the pipe. For Intake earth tubes, an appropriate amount of fan heat is added to the air stream.

#### **1.16.16.9 Field: Fan Pressure Rise**

This is the pressure rise experienced across the fan in Pascals ( $N/m^2$ ). This is a function of the fan and plays a role in determining the amount of energy consumed by the fan.

#### **1.16.16.10 Field: Fan Total Efficiency**

This is the total fan efficiency (a decimal number between 0.0 and 1.0). This is a function of the fan and plays a role in determining the amount of energy consumed by the fan.

#### **1.16.16.11 Field: Pipe Radius**

This is the radius of the earth tube/pipe (in meters). This plays a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe. If the pipe has non-circular cross section, user can use the concept of hydraulic diameter as follows.

$$D = 4 \times Area / Perimeter \quad (36)$$

However, since this field requires the pipe radius, hydraulic diameter should be divided by two.

#### **1.16.16.12 Field: Pipe Thickness**

This is the thickness of the pipe wall (in meters). This plays a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe.

#### **1.16.16.13 Field: Pipe Length**

This is the total length of the pipe (in meters). This plays a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe. As the length of the pipe becomes longer, the amount of the heat transfer becomes larger.

#### **1.16.16.14 Field: Pipe Thermal Conductivity**

This is the thermal conductivity of the pipe (in  $W/m^{\circ}C$ ). This plays a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe.

#### **1.16.16.15 Field: Pipe Depth Under Ground Surface**

This is the depth of the pipe under the ground surface (in meters). This plays a role in determining the temperature of the soil surrounding the pipe.

#### **1.16.16.16 Field: Soil Condition**

This alpha character string defines the actual condition of the soil surrounding the earth tube and can be one of any of the following options: HeavyAndSaturated, HeavyAndDamp, HeavyAndDry or LightAndDry. This determines the thermal diffusivity and thermal conductivity of the surrounding soil, which play a role in determining the amount of heat transferred from the surrounding soil to the air passing along the pipe.

#### **1.16.16.17 Field: Average Soil Surface Temperature**

This is the annual average soil surface temperature straight above the earth tube, which plays a role in determining the temperature of the soil surrounding the pipe. This field should be calculated in advance using the separate CalcSoilSurfTemp program.

#### **1.16.16.18 Field: Amplitude of Soil Surface Temperature**

This is the amplitude of soil surface temperature above the earth tube, which plays a role in determining the temperature of the soil surrounding the pipe. This is the difference between the maximum and minimum soil surface temperature for the whole year divided by two. This field should be calculated in advance using the separate CalcSoilSurfTemp program.

#### **1.16.16.19 Field: Phase Constant of Soil Surface Temperature**

This is the phase constant of the soil surface temperature straight above the earth tube, which play a role in determining the temperature of the soil surrounding the pipe at particular time. This is the time elapsed from the beginning of the year until the soil surface temperature reaches the minimum value of the year. This field should be calculated in advance using the separate CalcSoilSurfTemp program.

#### **1.16.16.20 Field: Constant Term Flow Coefficient**

This number is the “A” parameter in the above earth tube equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter, however, is a constant under all conditions and is not modified by any environmental effect. As a result, it is dimensionless.

#### 1.16.16.21 Field: Temperature Term Flow Coefficient

This number is the “B” parameter in the above earth tube equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the temperature difference between the outdoor and indoor air dry-bulb temperatures. The units for this parameter are inverse Celsius.

#### 1.16.16.22 Field: Velocity Term Flow Coefficient

This number is the “C” parameter in the above earth tube equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by the speed of wind being experienced outside the building. The units for this parameter are s/m.

#### 1.16.16.23 Field: Velocity Squared Term Flow Coefficient

This number is the “D” parameter in the above earth tube equation. It is part of the user specified modifying parameters that are a function of environmental factors. This parameter is modified by square of the speed of wind being experienced outside the building. The units for this parameter are s<sup>2</sup>/m<sup>2</sup>.

### 1.16.17 ZoneEarthTube Outputs

Current Earth Tube output variables:

- HVAC,Sum,Earth Tube Zone Sensible Cooling Energy [J]
- HVAC,Average,Earth Tube Zone Sensible Cooling Rate [W]
- HVAC,Sum,Earth Tube Zone Sensible Heating Energy [J]
- HVAC,Average,Earth Tube Zone Sensible Heating Rate [W]
- HVAC,Sum,Earth Tube Air Flow Volume [m3]
- HVAC,Average,Earth Tube Air Current Density Volumetric Flow Rate [m3/s]
- HVAC,Average,Earth Tube Air Standard Density Volumetric Flow Rate [m3/s]
- HVAC,Sum,Earth Tube Air Flow Mass [kg]
- HVAC,Average,Earth Tube Air Mass Flow Rate [kg/s]
- HVAC,Sum,Earth Tube Fan Electric Energy [J]
- HVAC,Average,Earth Tube Fan Electric Power [W]
- HVAC,Average,Earth Tube Zone Inlet Air Temperature [C]
- HVAC,Average,Earth Tube Ground Interface Temperature [C]

- HVAC,Average,Earth Tube Outdoor Air Heat Transfer Rate [W]

#### **1.16.17.1 Earth Tube Zone Sensible Cooling Energy [J]**

#### **1.16.17.2 Earth Tube Zone Sensible Cooling Rate [W]**

These are the energy and rate associated with the zone cooling provided by the air from the earth tube. This occurs when the earth tube outlet air temperature is less than zone air temperature.

#### **1.16.17.3 Earth Tube Zone Sensible Heating Energy [J]**

#### **1.16.17.4 Earth Tube Zone Sensible Heating Rate [W]**

These are the energy and rate associated with the zone heating provided by the air from the earth tube. This occurs when the earth tube outlet air temperature is greater than the zone air temperature.

#### **1.16.17.5 Earth Tube Air Flow Volume [m3]**

The volume flow of air through the earth tube.

#### **1.16.17.6 Earth Tube Air Current Density Volumetric Flow Rate [m3/s]**

The volume flow rate of air through the earth tube evaluating density at current zone conditions.

#### **1.16.17.7 Earth Tube Air Standard Density Volumetric Flow Rate [m3/s]**

The volume flow rate of air through the earth tube evaluating density at standard conditions.

#### **1.16.17.8 Earth Tube Air Flow Mass [kg]**

The mass flow of air through the earth tube.

#### **1.16.17.9 Earth Tube Air Mass Flow Rate [kg/s]**

The mass flow rate of air through the earth tube.

#### **1.16.17.10 Earth Tube Fan Electric Energy [J]**

#### **1.16.17.11 Earth Tube Fan Electric Power [W]**

These are the fan electricity consumption and power for intake or exhaust earth tube types.

#### **1.16.17.12 Earth Tube Zone Inlet Air Temperature [C]**

This is the temperature of the air entering the zone after passing through the earth tube [C]. This temperature includes the cooling or heating of outdoor air as it passes along the pipe. When intake fan assist is used, then the additional heat due to the fan is included in the inlet air temperature.

#### **1.16.17.13 Earth Tube Ground Interface Temperature [C]**

This is the average temperature of the ground along the outer surface of the earth tube [C].

#### **1.16.17.14 Earth Tube Outdoor Air Heat Transfer Rate [W]**

This is the rate of heat transfer from the earth tube to the outdoor air [W]. Positive values indicate the rate at which outdoor air is preheated; negative values indicate the rate of precooling.

### **1.16.18 ZoneCoolTower:Shower**

A cooltower (which is sometimes referred to as a wind tower or a shower cooling tower) is a component that is intended to model a passive downdraught evaporative cooling (PDEC) that is designed to capture the wind at the top of a tower and cool the outside air using water evaporation before delivering it to a space. The air flow in these systems is natural as the evaporation process increases the density of the air causing it to fall through the tower and into the space without the aid of a fan. A cooltower typically consists of a water spray or an evaporative pad, a shaft, and a water tank or reservoir. Wind catchers to improve the wind-driven performance at the top of the tower are optional. Water is pumped over an evaporative device by water pump which is the only component consumed power for this system. This water cools and humidifies incoming air and then the cool, dense air naturally falls down through shaft and leaves through large openings at the bottom of cooltowers.

The shower cooling tower can be controlled by a schedule and the specification of maximum water flow rate and volume flow rate as well as minimum indoor temperature. The actual flow rate of water and air can be controlled as users specify the fractions of water loss and flow schedule. The required input fields

include effective tower height and exit area to obtain the temperature and flow rate of the air exiting the tower. A schedule and rated power for the water pump are also required to determine the power consumed. The component typically has a stand alone water system that is not added to the water consumption from mains. However, users are required to specify the water source through an optional field, the name of water supply storage tank, in case any water comes from a water main. The model is described more fully in the Engineering Reference document.

This model requires weather information obtained from either design day or weather file specifications. The control is accomplished by either specifying the water flow rate or obtaining the velocity at the outlet with inputs and weather conditions when the water flow rate is unknown. As with infiltration, ventilation, and earth tubes, the component is treated in a similar fashion to "natural ventilation" in EnergyPlus.

#### **1.16.18.1 Field: Name**

This field is a unique user assigned name for each cooltower. Any reference to this unit by another object will use this name.

#### **1.16.18.2 Field: Availability Schedule Name**

This field is the name of the schedule that denotes whether the cooltower can run during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the cooltower is available and can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the cooltower is not available and must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

#### **1.16.18.3 Field: Zone Name**

This field is the name of the zone (ref: Zone) and attaches a particular cooltower statement to a thermal zone in the building.

#### **1.16.18.4 Field: Water Supply Storage Tank Name**

This field is optional. It is used to describe where the cooltower obtains water used for evaporative cooling. If blank or omitted, then the cooltower will obtain water directly from local water main. If the name of a Water Storage Tank object is used here, then the cooltower will obtain its water from that tank. If a tank is specified, the cooltower will attempt to obtain all the water it uses from the tank. However, if the tank cannot provide all the water the cooltower needs, then the cooltower will still operate and obtain the rest of the water it needs from the mains (referred to as 'Starved' water).

#### **1.16.18.5 Field: Flow Control Type**

This field specifies how the user wishes to control the cooltower. The air flow from the cooltower may be controlled by either the water flow rate along with the water pump schedule or naturally driven by wind flow. The user must select from the following options: **WaterFlowSchedule** and **WindDrivenFlow**. If the user either wishes to control the water flow rate or has information about the water flow rate, **WaterFlowSchedule** must be selected. **WindDrivenFlow** for cooltower flow control must be selected when the water flow rate is unknown and the user wishes to have the flow rate of both air and water controlled by the external weather conditions (wind speed). If the user does not select a control type, **WindDrivenFlow** is assumed as a flow control type.

#### **1.16.18.6 Field: Pump Flow Rate Schedule Name**

This field modifies the maximum flow rate of water through the cooltower in m3/sec. This input is "optional." If the user does not enter a schedule, the flow rate through the cooltower is assumed to be constant during all hours that it is operating based on the value entered in the previous input field. Note that the values for this schedule must be between zero and one.

#### **1.16.18.7 Field: Maximum Water Flow Rate**

This field is the maximum water flow rate distributed to the tower in m3/s. This limit is intended to avoid over estimation of water flow rate, which leads higher air flow rate and exit temperature of the air.

#### **1.16.18.8 Field: Effective Tower Height**

This field is the effective tower height for evaporative cooling, from the water spray to the top of the exit in m.

#### **1.16.18.9 Field: Airflow Outlet Area**

This field is the area at the exit of the tower in m2. This field is used to determine the air flow rate leaving the tower with the velocity of the air flow.

#### **1.16.18.10 Field: Maximum Air Flow Rate**

This field is the maximum volumetric flow rate of the air leaving the tower in m3/s. This airflow maximum allows the cooltower performance to be limited if the outside wind speed and the tower height are relatively high and thus result in high airflow supplied to the space.

#### **1.16.18.11 Field: Minimum Indoor Temperature**

This field is the minimum indoor temperature in Celsius below which cooltower is shutoff. This lower temperature limit is intended to avoid overcooling a space and thus result in a heating load. For example, if the user specifies a minimum temperature of 20°C, cooltower is assumed to be available if the zone air temperature is above 20°C. If the zone air temperature drops below 20°C, then cooltower is automatically turned off.

#### 1.16.18.12 Field: Fraction of Water Loss

This field specifies the fraction of the loss of water during either operation or transient operation. If the user does not enter a fraction, no loss of water is assumed and the cooltower water consumption includes only evaporation. Note that the fraction must be between zero and one.

#### 1.16.18.13 Field: Fraction of Flow Schedule

This field specifies the fraction of the airflow that actually goes to the outside. The user who wishes to control the actual flow to the inside of the building must specify the value of the fraction. If the user does not enter a fraction, the calculated flow rate is the “zone cooltower volume flow rate.” Note that the fraction must be between zero and one.

#### 1.16.18.14 Field: Rated Power Consumption

This field is the pump’s rated power consumption in Watts.

Below is an example input for a cooltower.

```
ZoneCoolTower:Shower
Cool Tower 1,      !- Name of cooltowers
Zone 1,           !- Zone name
Simple Vent,      !- Schedule
,                !- Name of water supply storage tanks
WindDrivenFlow,  !- Flow control type
0.0005,          !- Water flow rate from the spray in m3/s
,                !- schedule for flow rate (optional, non-existent means constant)
5.0,             !- Effective tower height in m
1.0,             !- Exit area in m2
10.0,            !- Maximum supply air volume flow rate in m3/s
18.0,            !- Minimum indoor temperature to prevent overcooling in C
0.05,            !- Fraction of Water loss
0.05,            !- Fraction of flow that goes to outside
250.0;           !- Rated power consumption in W
```

#### 1.16.19 ZoneCoolTower:Shower Outputs

- HVAC,Sum,Zone Cooltower Sensible Heat Loss Energy [J]

- HVAC,Sum,Zone Cooltower Storage Tank Water Volume [m3]
- HVAC,Sum,Zone Cooltower Starved Mains Water Volume [m3]

##### 1.16.19.1 Zone Cooltower Sensible Heat Loss Energy [J]

#### **1.16.19.2 Zone Cooltower Sensible Heat Loss Rate [W]**

The sensible heat loss that occurs when the temperature at the exit of the cooltower is less than that of the zone.

#### **1.16.19.3 Zone Cooltower Latent Heat Loss Energy [J]**

#### **1.16.19.4 Zone Cooltower Latent Heat Loss Rate [W]**

The latent heat loss that occurs when the humidity ratio at the exit of the cooltower is greater than that of the zone.

#### **1.16.19.5 Zone Cooltower Air Current Density Volumetric Flow Rate [m<sup>3</sup>/s]**

The volumetric flow rate of the air leaving the cooltower evaluating density at current zone conditions.

#### **1.16.19.6 Zone Cooltower Air Standard Density Volumetric Flow Rate [m<sup>3</sup>/s]**

The volumetric flow rate of the air leaving the cooltower evaluating density at standard conditions.

#### **1.16.19.7 Zone Cooltower Air Volume [m<sup>3</sup>]**

The sum of actual volumetric flow of the air leaving cooltower

#### **1.16.19.8 Zone Cooltower Air Mass Flow Rate [kg/s]**

The mass flow rate of the air leaving the cooltower

#### **1.16.19.9 Zone Cooltower Air Mass [kg]**

The sum of actual mass flow of the air leaving the cooltower

#### **1.16.19.10 Zone Cooltower Air Inlet Temperature [C]**

The dry-bulb temperature of the outdoor air the inlet of the cooltower

#### **1.16.19.11 Zone Cooltower Air Inlet Humidity Ratio [kgWater/kgDryAir]**

The humidity ratio of the outdoorair at the inlet of the cooltower

#### **1.16.19.12 Zone Cooltower Air Outlet Temperature [C]**

The temperature at the exit of the cooltower.

#### **1.16.19.13 Zone Cooltower Air Outlet Humidity Ratio [kgWater/kgDryAir]**

The humidity ratio of the air at the exit of the cooltower.

#### **1.16.19.14 Zone Cooltower Water Volume [m<sup>3</sup>]**

The water consumption includes not only the direct thermodynamics of water evaporation but also other sources of consumption such as drift or concentration blow down specified by users throughout all processes during the operation.

#### **1.16.19.15 Zone Cooltower Mains Water Volume [m<sup>3</sup>]**

This is the water consumed by the cooltower that actually be met by the mains water. This output variable appears only when the water comes from mains.

#### **1.16.19.16 Zone Cooltower Storage Tank Water Volume [m<sup>3</sup>]**

This is the water consumed by the cooltower that actually be met by the water storage tank. If any amount of the water is starved from mains, this water consumption is the difference between the Zone Cooltower Water Volume and the following output. This output variable appears only when the water comes from storage tank waters.

#### **1.16.19.17 Zone Cooltower Starved Mains Water Volume [m<sup>3</sup>]**

This is the source (mains) of water consumed by the cooltower that could not actually be met by the storage tank. This output variable appears only when the water comes from storage tank waters.

#### **1.16.19.18 Zone Cooltower Pump Electric Power [W]**

The power consumed by the recirculating pump in Watts.

#### **1.16.19.19 Zone Cooltower Pump Electric Energy [J]**

The energy consumed by the recirculating pump in Joules.

#### **1.16.20 ZoneThermalChimney (Thermal Chimney)**

A thermal chimney is a vertical shaft utilizing solar radiation to enhance the natural ventilation in buildings. It consists of a absorber wall, air gap and glass cover with high solar transmissivity. For the high solar absorption, it is usually south facing.

The key output parameter in the thermal chimney model is the enhanced amount of natural ventilation rate caused by the presence of a thermal chimney. In order to determine the enhanced ventilation, the discharge air temperature from a thermal chimney should be calculated, which, in turn, should be computed based on the information on the absorber wall temperature, glass cover temperature and the vertical air temperature distribution within the thermal chimney. Among them, energy balances for the absorber wall and the glass cover are carried out using the existing algorithm currently available in EnergyPlus, which has the similar approach to the Trombe wall. As stated in the Trombe wall object as well, this approach allows the flexibility for users to specify the various wall parameters and to explore unusual configurations. On the other hand, the vertical air temperature distribution and the resultant discharge air temperature of the thermal chimney are computed using the separate thermal chimney algorithm described in the Engineering Reference document.

Similar to the Trombe wall model, a zone is coupled to the desired surface via an interzone partition. To simulate the thermal chimney, the Solar Distribution field in the Building object should be set to FullInteriorAndExterior so that the majority of the solar flux is directed on the absorber wall. For a normal sized thermal chimney zone, the user can set the Zone Inside Convection Algorithm to "Detailed", which takes into account natural convection effects intended for a normal zone. For a narrow cavity zone having high aspect ratios, there is no built-in algorithm for calculating the correct convection coefficients on the inside of thermal chimney zone walls. One option is to use the "Detailed" convection algorithm similar to the Trombe wall model. However, some error may be incurred when used with a narrow zone. Another option is to use the SurfaceProperty:ConvectionCoefficients object to schedule coefficients that have been determined beforehand by the user. In addition, the wall construction of the adjoining zone must be the mirror image of the wall construction in the thermal chimney zone.

The full input description of a thermal chimney in EnergyPlus is given below.

##### **1.16.20.1 Field: Name**

This field is a unique user assigned name for an instance of the thermal chimney system.

##### **1.16.20.2 Field: Zone Name**

This field is the name of the thermal chimney zone (ref: Zone). Since the thermal chimney is not only a system component but also a zone itself, this field is also necessary. It should be differentiated from the *Zone name* field described later.

##### **1.16.20.3 Field: Availability Schedule Name**

This field is the name of the schedule (ref: Schedule) that denotes whether the thermal chimney can operate during a given time period. A schedule value greater than 0 (usually 1 is used) indicates that the system is available and can be on during the time period. A value less than or equal to 0 (usually 0 is used) denotes that the system is not available and must be off for the time period. If this field is blank, the schedule has values of 1 for all time periods.

##### **1.16.20.4 Field: Width of the Absorber Wall**

This number is the width of the absorber wall in the thermal chimney. The width is expressed in units of m. Even though this value is specified in Surface objects as well, this value is used to compute the discharge air temperature and the enhanced ventilation rate caused by the thermal chimney.

##### **1.16.20.5 Field: Cross Sectional Area of Air Channel Outlet**

This number is the cross sectional area of air channel outlet. The area is expressed in units of  $m^2$ . The enhanced air flow rate by the thermal chimney is dependent on cross sectional areas of air channel inlet and outlet. Cross sectional areas of air channel inlet will be described later in conjunction with the distance from the top of thermal chimney to each inlet and relative ratios of air flow rates passing through each inlet.

##### **1.16.20.6 Field: Discharge Coefficient**

This dimensionless number is the discharge coefficient of the thermal chimney. The ventilation rate enhanced by the thermal chimney is also dependent on the discharge coefficient.

##### **1.16.20.7 Field: Zone <#> Name**

This field is the name of the zone (ref: Zone) to which the thermal chimney is attached. It is used in conjunction with the next three fields. Note that up to 20 sets of zone name, distance from the top of the thermal chimney to each inlet, relative ratios of air flow rates passing through each zone and cross sectional areas of each air channel inlet may be entered for a single thermal chimney if multiple zones share the common thermal chimney.

##### **1.16.20.8 Field: Distance from Top of Thermal Chimney to Inlet <#>**

This field is the distance from the top of the thermal chimney to each inlet corresponding to each zone. It is used in conjunction with the zone name, relative ratios of air flow rates passing through each zone and cross sectional areas of each air channel inlet. The distance is expressed in units of m. The air flow rate enhanced by the thermal chimney is dependent on the distance between the thermal chimney outlet and inlet.

#### 1.16.20.9 Field: Relative Ratios of Air Flow Rates Passing through Zone <#>

This dimensionless number is the relative ratio of air flow rates enhanced by the thermal chimney passing through each zone. The total air flow rate enhanced by the thermal chimney is distributed to each zone based on this number if multiple zones share the common thermal chimney. It is used in conjunction with the zone name, the distance from the top of the thermal chimney to each inlet and cross sectional areas of each air channel inlet. Note that the sum of all ratios must be equal to 1.0.

#### 1.16.20.10 Field: Cross Sectional Areas of Air Channel Inlet <#>

This field is the cross sectional areas of each air channel inlet corresponding to each zone. It is used in conjunction with the zone name, the distance from the top of the thermal chimney to each inlet and relative ratios of air flow rates passing through each zone. The area is expressed in units of m<sup>2</sup>. The air flow rate enhanced by the thermal chimney is dependent on cross sectional areas of air channel inlet and outlet.

- HVAC,Sum,Zone Thermal Chimney Volume [m3]
- HVAC,Sum,Zone Thermal Chimney Mass [kg]

#### 1.16.21.1 Zone Thermal Chimney Heat Loss Energy [J]

The sensible (temperature) heat loss of each zone that occurs when the thermal chimney cools the zone air.

#### 1.16.21.2 Zone Thermal Chimney Heat Gain Energy [J]

The sensible (temperature) heat gain of each zone that occurs when the thermal chimney heats the zone air.

#### 1.16.21.3 Zone Thermal Chimney Volume [m3]

The air volumetric flow of each zone enhanced by the thermal chimney.

#### 1.16.21.4 Zone Thermal Chimney Mass [kg]

The air mass flow of each zone enhanced by the thermal chimney.

#### 1.16.21.5 Zone Thermal Chimney Current Density Volumetric Flow Rate [m3/s]

The total air volumetric flow rate caused by the thermal chimney evaluating density at the current zone conditions.

#### 1.16.21.6 Zone Thermal Chimney Standard Density Volumetric Flow Rate [m<sup>3</sup>/s]

The total air volumetric flow rate caused by the thermal chimney evaluating density at standard conditions.

#### 1.16.21.7 Zone Thermal Chimney Mass Flow Rate [kg/s]

The total air mass flow rate caused by the thermal chimney.

#### 1.16.21.8 Zone Thermal Chimney Outlet Temperature [C]

The temperature of the air which is discharged from the thermal chimney through the outlet.

### 1.16.22 ZoneAirMassFlowConservation

This global object allows users to trigger the zone air mass flow conservation calculation when desired. This object has three input fields; the first choice input field allows the user whether to adjust mixing flows to enforce the zone air mass flow conservation; and the other fields allows the user to specify how infiltration object mass flow rate is calculated for zone air mass flow balance calculation. If adjustments for either mixing or infiltration is specified then the zone air mass balance attempts to enforce conservation. If both mixing and infiltration adjustments are off, then the zone air mass flow calculation uses the default method which does not include zone mixing objects and assumes self-balanced simple infiltration. The default method may not necessarily enforce zone air mass flow conservation unless the user has specified a balanced flow to begin with. The zone air mass flow conservation primarily accounts for the zonemixing objects air flow in the zone air flow mass balance calculation. In addition to the zonemixing object flow, the procedure accounts for zone supply, exhaust, and return flows and adjusts infiltration air flows (up or down) when required in order to balance the zone air mass flow. Mixing and infiltration adjustments will only be made in zones which have zonemixing or infiltration objects defined in the input. For example, if a zone does not have any infiltration objects, then no infiltration adjustment will be made for that zone.

First, the ZoneMixing object mass flow rate is adjusted or modified in order to balance zone air mass flow while assuming any zone infiltration objects are self-balanced. This step will always results in balanced zone air mass for receiving zones of ZoneMixing object but it may not necessarily result in a balanced air mass flow for source zones.

Second, infiltration flow rates are adjusted according to the options set. Infiltration flow will be increased or decreased to balance the net flow from supply, exhaust, mixing, and return air flows. If a negative infiltration rate (exfiltration) is required to balance a zone's airflow, then the infiltration rate will be set to zero. This can happen, for example, if the total supply flow exceeds the total exhaust plus return flow.

This object is optional. If it is not present in the input file, the default zone air mass flow calculation are used which do not account for zonemixing and infiltration flows.

#### 1.16.22.1 Field: Adjust Zone Mixing For Zone Air Mass Flow Balance

This field has two choices: *Yes* or *No*. When set to *Yes*, the zone air mass flow balance attempts to enforce conservation by adjusting zone mixing flow rates. When set to *No*, mixing flow rates are not adjusted; the mixing flows specified in ZoneMixing objects will be used. The default is *No*.

#### 1.16.22.2 Field: Infiltration Balancing Method

This field has three choices: *AddInfiltrationFlow*, *AdjustInfiltrationFlow*, or *None*. The default is *AddInfiltrationFlow*. With all three options, the base infiltration flow rate is the flow specified in all Infiltration:\* objects for a given zone.

*AddInfiltrationFlow*: The base infiltration flow may be increased in order to balance the zone air mass flow. This additional infiltration air mass flow is not self-balanced, i.e., it is always assumed to be incoming flow which leaves by exhaust, mixing, or return. If no infiltration air is required in order to balance the zone air mass flow, then the additional infiltration air mass flow rate is set to zero. For this option, the base infiltration flow is always assumed to be self-balanced (i.e., exfiltration = infiltration) and is not included in the zone air mass flow balance.

*AdjustInfiltrationFlow*: The base infiltration flow may be increased or decreased in order to balance the zone air mass flow. If no infiltration is required to balance the zone air flow, then the base infiltration flow rate is retained and assumed to be self-balanced (i.e., exfiltration = infiltration). If the required infiltration flow rate is negative (exfiltration), then the infiltration flow rate is set to zero and surplus flow in the zone is assumed to leave as exfiltration.

*None*: The base infiltration flow is always assumed to be self-balanced (i.e., exfiltration = infiltration) and is not included in the zone air mass flow balance. No changes are made to the base infiltration flow rate.

#### 1.16.22.3 Field: Infiltration Balancing Zones

This field allows user to choose which zones are included in infiltration balancing. There are two choices *MixingSourceZoneOnly* or *AllZones*.

*MixingSourceZonesOnly*: Infiltration balancing is active only in zones which are source zones for mixing and which have a base infiltration object defined.

*AllZones*: Infiltration balance is active in any zone which has a base infiltration object defined.

An IDF example is shown below:

```
ZoneAirMassFlowConservation,  
  Yes, !- Adjust Zone Mixing For Zone Air Mass Flow Balance  
  AdjustInfiltrationFlow; !- Infiltration Balancing Method  
  AllZones; !- Infiltration Balancing Zones
```

### 1.16.23 ZoneAirMassFlowConservation Outputs

Current ZoneAirMassFlowConservation output variables (only applicable variables will be generated):

- HVAC, Average, Zone Air Mass Balance Supply Mass Flow Rate [kg/s]
- HVAC, Average, Zone Air Mass Balance Exhaust Mass Flow Rate [kg/s]
- HVAC, Average, Zone Air Mass Balance Return Mass Flow Rate [kg/s]
- HVAC, Average, Zone Air Mass Balance Mixing Receiving Mass Flow Rate [kg/s]
- HVAC, Average, Zone Air Mass Balance Mixing Source Mass Flow Rate [kg/s]
- HVAC, Average, Zone Infiltration Air Mass Flow Balance Status, []
- HVAC, Average, Zone Mass Balance Infiltration Air Mass Flow Rate, [kg/s]

#### 1.16.23.1 Zone Air Mass Balance Supply Mass Flow Rate [kg/s]

This output variable represents the total supply air mass flow rate of a zone. The value is determined by summing the supply air mass flow rates contributions from all supply air inlet nodes of a zone.

#### 1.16.23.2 Zone Air Mass Balance Exhaust Mass Flow Rate [kg/s]

This output variable represents the total exhaust air mass flow rate of a zone. The value is determined by summing the exhaust air mass flow rates contributions from all exhaust air nodes of a zone.

#### 1.16.23.3 Zone Air Mass Balance Return Mass Flow Rate [kg/s]

This output variable represents the total return air mass flow rate of a zone. The value is determined by summing the return air mass flow rates contributions from return air nodes of a zone.

#### 1.16.23.4 Zone Air Mass Balance Mixing Receiving Mass Flow Rate [kg/s]

This output variable represents the total zone mixing air mass flow rate of a receiving zone from one or more mixing objects. The value is determined by summing the air mass flow contributions from all zone mixing objects connected to a single receiving zone.

#### 1.16.23.5 Zone Air Mass Balance Mixing Source Mass Flow Rate [kg/s]

This output variable represents the total zone mixing source air mass flow rate of a source zone feeding one or more mixing objects. The value is determined by summing the air mass flow contributions from all zone mixing objects connected to a single source zone.

#### 1.16.23.6 Zone Air Mass Balance Infiltration Status []

This output variable indicates the status of the infiltration object mass flow rate use for balancing the zone mass flow at each time step. It has values of either **0** or **1**. If the value of this report variable is **0** then the zone infiltration object mass flow rate is not used in the zone mass conservation calculation, hence the infiltration rate calculated based on the user specified inputs is maintained and the infiltration rate is assumed as self-balanced for the current timestep. If the value is **1** then the zone infiltration object mass flow rate is included in the zone air mass flow balance calculation, hence the user specified infiltration rate is modified and it is considered as incoming flow to the zone, i.e., self-balanced assumption is not valid for this zone and current time step.

#### 1.16.23.7 Zone Air Mass Balance Infiltration Mass Flow Rate [kg/s]

This output variable represents the zone infiltration air mass flow rate in kg/s. This output variable is reported only for source zones and when the zone air mass flow balance is active. Its value depends on the Infiltration Balancing Method specified. When the infiltration method is *AddInfiltrationFlow* this output represents the additional infiltration air mass flow rate added on top of the base infiltration air flow in order to balance the zone air mass flow. In this case, the base infiltration air mass flow calculated using the user specified input is assumed self-balanced. When the infiltration method is *AdjustInfiltrationFlow* and the value of "Zone Air Mass Balance Infiltration Status" is **1**, this output represents the infiltration air mass flow rate required to balance the zone air mass flow. This value could be negative if the zone supply exceeds all other outflows. If the value of "Zone Air Mass Balance Infiltration Status" is **0**, then this output is the self-balanced base infiltration flow rate for current timestep.

## 1.17 Group – Design Objects

## 1.17.1 Input for Design Calculations and Component Autosizing

### 1.17.1.1 Overview

In order for EnergyPlus to successfully calculate zone design heating and cooling loads and air flow rates and for the program to use these results to automatically size the HVAC components a number of input objects must be present and certain object input fields must be entered.

- The input file should contain a SimulationControl object. The 1<sup>st</sup> field *Do Zone Sizing Calculation* should be entered as *Yes*. This will cause a zone sizing simulation to be done using all the sizing periods in the input file as weather. If there are no air or water loops in the HVAC input fields 2 and 3 can be set to *No*. If there are one or more air loops (i.e., there is at least one AirLoopHVAC object in the input file) then the 2<sup>nd</sup> field *Do System Sizing Calculation* should be entered as *Yes*. If there are one or more water loops (Plant Loop objects) then the 3<sup>rd</sup> field *Do Plant Sizing Calculation* should be set to *Yes*. Finally either the 4<sup>th</sup> field (*Run Simulation for Sizing Periods*) or the 5<sup>th</sup> field (*Run Simulation for Weather File Run Periods*) should be set to *Yes* in order to autosize the components and do a real simulation using the autosized components. The component autosizing calculations are done on the first pass through the HVAC system in the real simulation.
- There must be at least 2 (up to any number) SizingPeriod objects present. Normally one will be for summer conditions and one for winter. The summer day should normally have the field *Day Type* set to *SummerDesignDay*. The winter design day should normally have *Day Type* set to *WinterDesignDay*.
- To apply a global sizing factor include the Sizing:Parameters object.
- For each controlled zone in the input file there should be a corresponding Sizing:Zone object. Similarly for each AirLoopHVAC there should be a Sizing:System object. And for each Plant or Condenser Loop there should be a Sizing:Plant object. Note however that if a controlled zone has no corresponding Zone Sizing object the data from the first Zone Sizing object will be used. Thus if all the zone sizing information is the same only one Zone Sizing object need be entered.
- Only controlled zones are included in the zone and system sizing calculations. Thus for a design air flow rate to be calculated for a zone, it must contain a thermostat *even though it might not need or have a thermostat in the full simulation* An illustration would be a three zone building with a packaged single zone system and a thermostat in one of the zones. In order for the two slave zones to be included in the design air flow calculations they must be treated as if they have a thermostat: there must be a ZoneControl:Thermostat for each of the slave zones.
- Some attention should be paid to schedules. In a weekly schedule object the 9<sup>th</sup> and 10<sup>th</sup> day schedules are for summer and winter design days respectively. This means that if a SizingPeriod object has field *Day Type* set to *SummerDesignDay* the day schedule for summer sizing periods will be in effect. Similarly if a SizingPeriod object has field *Day Type* set to *WinterDesignDay* the day schedule for winter sizing periods will be in effect. Some possible applications of this capability are:
  - 1) setting internal loads (lights, equipment, occupancy) to maximum all day for cooling and to zero all day for heating;
  - 2) setting heating and cooling thermostat set points to constant values (no set up or set back);
  - 3) setting heating and cooling equipment to be always on.

None of these applications are necessarily recommended but these and other uses of the special summer/winter design day schedules may prove useful for specific situations.

- Other than zone thermostat setpoints, the sizing calculations generally know nothing about the system control inputs such as setpoints and availability schedules. The user must coordinate sizing inputs with the actual simulation control inputs.
- The sizing calculations only recognize the presence of central heating and cooling coils, preheat and precool coils and reheat coils. These are assumed to deliver the various supply temperatures specified in the Sizing:System and Sizing:Zone objects. The impact of other components such as heat recovery, dehumidifiers, and pumps are not accounted for in the sizing calculations. Central supply and return fan temperature rise is taken into account in sizing the central cooling coils.

### 1.17.1.2 Component Autosizing

For autosizing to occur at the component level the user must enter the special value *autosize* in the numeric fields for which autosizing is available. Those fields can be found by looking at the Energy+.idd data dictionary file or under individual object details in this document. Fields that can be autosized are denoted with the comment *!autosizable*. The components and fields that are autosizable are listed in the following table. Note that spaces may be inserted in object names to facilitate readability.

Table 22. Details of Autosizable Objects/Fields

There are 3 places in the input where the user can impose sizing factors.

1. In Sizing Parameters (object: Sizing:Parameters), the user can specify an over-all sizing factor. This factor is applied to all the zone design loads and air flow rates resulting from the zone sizing calculations.
2. In Zone Sizing (object: Sizing:Zone), the user can specify a sizing factor for a specific zone. The factor is applied to the calculated zone design loads and air flow rates for the zone named in the Sizing:Zone object. This sizing factor overrides the global sizing factor. That is, a zone sizing factor, if specified, replaces the global sizing factor for the named zone.
3. For some plant components (basically all central chillers, boilers and cooling towers) the user can specify a sizing factor that modifies the autosized component capacity and flow rates. These factors are applied after the application of global or zone sizing factors. They are primarily used to split the design load between multiple components. These sizing factors can change the autosizing of the associated loops and pumps. The following rules are followed the effect of plant component sizing factors on loops and pumps.
  - a. For supply side branches, the sizing factors of all components in series on the branch are summed and the result becomes the branch sizing factor. If there is a branch pump its autosized design flow rate is multiplied by the branch sizing factor.
  - b. For each loop, if the average of the branch sizing factors is less than 1, the loop sizing factor is set equal to the sum of the branch sizing factors. If the average is greater than 1, the loop sizing factor is set equal to the maximum of the branch sizing factors. The loop sizing factor is applied to the loop design flow rate (if autosized) and to the loop pump flow rate (if autosized).

### 1.17.1.3 Mixing User-Specified and Autosized Inputs

Mixed user-specified and autosized inputs can be successfully used if the following points and suggestions are followed.

1. Each component is autosized independently. Thus user input for a flow rate in one component will have no effect on other components' autosized flow rates. For instance, specifying the chilled water loop pump's rated flow rate will have no effect on the autosizing of the chiller's design evaporator flow rate or on the plant loop's autosized maximum loop flow rate.
2. Within a component it is best to autosize all inputs are enter specified values for all inputs. For example, in a chiller, if only the nominal capacity is user-specified, the autosized chilled water flow rate may not be consistent with the specified capacity.
3. Sizing information flows only from the sizing objects to the components. The sizing calculations have no knowledge of user-specified values in a component. The only exception to this rule is that plant loop sizing will collect all component design water flow rates whether autosized or user-specified.
4. If the user wants to specify a zone or system air flow rate it should be done using the Sizing:Zone and Sizing:System objects rather than done in the individual components.
5. The plant loop flow rates are sized from the total design demand of the components connected to each loop. The components demanding water need not be autosized for the plant loop autosizing to work successfully. So the user could specify all the air side components and autosize all the plant loops and plant components. Or specify the chilled water loop flow rate, chilled water pump inputs and chiller inputs and let the condenser loop and tower autosize.

### 1.17.1.4 Component Sizing Output

The results of the component autosizing calculations are reported on the *plusout.eio* file. For each component field that has been autosized the object type, object name, field description with unit, and value are printed out as comma separated data on a line beginning with *Component Sizing*. Examples of this are shown in the Output Details and Examples document.

The complete list of objects that have autosized fields is shown in the following table. Note that spaces may be inserted in object names to facilitate readability.

### 1.17.1.5 User or External Zone Design Flow Rate Inputs

In EnergyPlus the autosizing calculations start with a calculation of the zone design air flow rates using zone by zone design day simulations. The resulting zone design air flow rates and daily air flow sequences are used in the subsequent HVAC and central plant air and fluid flow design calculations and in the component autosizing calculations. The user can override or change the calculated zone design air flow rates in several ways.

- 1) The user can enter a value for *Sizing Factor* in the *Sizing:Parameters* object (see description below).
- 2) The user can specify a zone level *Zone Sizing Factor* in each *Sizing:Zone* object.
- 3) For each zone the user can input a *Cooling Design Air Flow Rate* and/or a *Heating Design Air Flow Rate* (and specify *Cooling Design Air Flow Method = Flow/Zone* and *Heating Design Air Flow Method = Flow/Zone*). These user inputs override the calculated values. The program divides the user input cooling or heating design air flow rate by the calculated values and uses the result as a zone sizing factor to multiply all the elements in the design heating and cooling air flow and load sequences. From this point the design calculations proceed as usual.

### 1.17.1.6 User or External System Design Flow Rate Inputs

Using the results of the zone design air flow rate calculation (including any user input or altered flow rates) EnergyPlus proceeds to calculate central air system flow rates and cooling and heating loads. The results of this calculation can be overridden in the following way.

For each system (AirLoopHVAC), in the corresponding *Sizing:System* object, specify *Cooling Design Air Flow Method* to be *Flow/System* and input a value for *Cooling Design Air Flow Rate*. Similarly for heating specify *Heating Design Air Flow Method* to be *Flow/System* and input a value for *Heating Design Air Flow Rate*.

## 1.17.2 DesignSpecification:OutdoorAir

This object allows for the outdoor air requirements to be defined in a common location for use by other objects. This object may be referenced by name from other objects (e.g., VAV terminal units) as required to identify an outdoor air quantity for use by that object. Note that a zone name is not included as an input to this zone outdoor air definition and the number of people in a zone, zone floor area, and zone volume can only be determined after this object has been referenced by another. A single zone outdoor air definition may be referenced by multiple objects to specify that the same outdoor air requirements are used by those objects or multiple zone outdoor air objects may be defined and referenced by other objects as needed. If multiple zone outdoor air definitions are used, each outdoor air definition must have a unique name.

### 1.17.2.1 Field: Name

Unique identifying name. Any reference to this name by other objects will denote that the following outdoor air requirements will be used.

### 1.17.2.2 Field: Outdoor Air Method

The input must be either *Flow/Person*, *Flow/Area*, *Flow/Zone*, *AirChanges/Hour*, *Sum*, or *Maximum*. *Flow/Person* means the program will use the input from the field *Outdoor Air Flow per Person* and the actual zone occupancy to calculate a zone outdoor air flow rate. *Flow/Area* means that the program will use the input from the field *Outdoor Air Flow per Zone Floor Area* and the actual zone floor area as the zone outdoor air flow rate. *Flow/Zone* means that the program will use the input of the field *Outdoor Air Flow per Zone* as the zone outdoor air flow rate. *AirChanges/Hour* means that the program will use the input from the field *Air Changes per Hour* and the actual zone volume (divided by 3600 seconds per hour) as the zone outdoor air flow rate. *Sum* means that the flows calculated from the fields *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area*, *Outdoor Air Flow per Zone*, and *Air Changes per Hour* (using the associated conversions to m<sup>3</sup>/s for each field) will be added to obtain the zone outdoor air flow rate. *Maximum* means that the maximum flow derived from *Outdoor Air Flow per Person*, *Outdoor Air Flow per Area*, *Outdoor Air Flow per Zone*, and *Air Changes per Hour* (using the associated conversions to m<sup>3</sup>/s for each field) will be used as the zone outdoor air flow rate. The default is *Flow/Person*.

### 1.17.2.3 Field: Outdoor Air Flow per Person

The design outdoor air volume flow rate per person for this zone in cubic meters per second per person. The default is 0.00944 (20 cfm per person). An outdoor air flow rate is calculated based on the total number of people for all *People* statements assigned to the zone. Occupancy schedule values are not applied during sizing calculations and are applied during the remainder of the simulation. This input is used if *Outdoor Air Method* is one of *Outdoor Air Flow per Person*, *Sum*,

or *Maximum*.

#### 1.17.2.4 Field: Outdoor Air Flow per Zone Floor Area

The design outdoor air volume flow rate per square meter of floor area (units are  $\text{m}^3/\text{s}\cdot\text{m}^2$ ). This input is used if *Outdoor Air Method* is *Flow/Area*, *Sum* or *Maximum*. The default value for this field is 0.

#### 1.17.2.5 Field: Outdoor Air Flow per Zone

The design outdoor air flow rate for this zone in cubic meters per second. This input field is used if *Outdoor Air Method* is *Flow/Zone*, *Sum* or *Maximum*. The default value for this field is 0.

#### 1.17.2.6 Field: Outdoor Air Flow Changes per Hour

The design outdoor air volume flow rate in air changes per hour. This factor is used along with the Zone Volume and converted to cubic meters per second. This input field is used if *Outdoor Air Method* is *AirChanges/Hour*, *Sum* or *Maximum*. The default value for this field is 0.

#### 1.17.2.7 Field: Outdoor Air Flow Rate Fraction Schedule Name

This field is the name of schedule that defines how outdoor air requirements change over time. The field is optional. If used, then the schedule values are multiplied by the outdoor air flow rate defined by the previous fields. The schedule values must be between 0 and 1, inclusive.

An IDF example:

```
DesignSpecification:OutdoorAir
  ZoneOAData,           !- Name

  For: AllOtherDays,     !- Field 5
  Until: 24:00, 0.5;     !- Field 7
```

### 1.17.3 DesignSpecification:ZoneAirDistribution

This object is used to describe the air distribution effectiveness and fraction of secondary recirculation air (return air not directly mixed with outdoor air) of a zone. It is referenced by the *Sizing:Zone* and *Controller:MechanicalVentilation* objects.

#### 1.17.3.1 Field: Name

The unique user assigned name for an instance of this object. Any other object referencing this object will use this name.

#### 1.17.3.2 Field: Zone Air Distribution Effectiveness in Cooling Mode

The positive numeric input for this field is the zone air distribution effectiveness when the zone is in cooling mode. Default value of this field is 1.0. ASHRAE Standard 62.1-2010 provides typical values.

#### 1.17.3.3 Field: Zone Air Distribution Effectiveness in Heating Mode

The positive numeric input for this field is the zone air distribution effectiveness when the zone is in heating mode. Default value of this field is 1.0. ASHRAE Standard 62.1-2010 provides typical values as follows:

Figure 71. Zone Air Distribution Effectiveness (Source: ASHRAE Standard 62.1-2010)

#### 1.17.3.4 Field: Zone Air Distribution Effectiveness Schedule Name

This optional field input points to a schedule with values of zone air distribution effectiveness. It provides a more flexible way of specifying zone air distribution effectiveness if it changes with time and/or system operating status and controls. If the schedule is specified, the zone air distribution effectiveness in cooling mode and heating mode will be ignored.

#### 1.17.3.5 Field: Zone Secondary Recirculation Fraction

The non-negative numeric input for this field is the fraction of a zone's recirculation air that does not directly mix with the outdoor air. The zone secondary recirculation fraction  $E_r$  is determined by the designer based on system configuration. For plenum return systems with secondary recirculation (e.g., fan-powered VAV with plenum return)  $E_r$  is usually less than 1.0, although values may range from 0.1 to 1.2 depending upon the location of the ventilation zone relative to other zones and the air handler. For ducted return systems with secondary recirculation (e.g., fan-powered VAV with ducted return),  $E_r$  is typically 0.0, while for those with system-level recirculation (e.g., dual-fan dual-duct systems with ducted return)  $E_r$  is typically 1.0. For other system types,  $E_r$  is typically 0.75. Minimum is 0.0, and default is 0.0 for single-path systems (also to maintain backward compatibility). For parallel fan-powered VAV systems, the secondary ventilation path only functions ( $E_r > 0.0$ ) when the fans in the VAV boxes operate, which is during heating. The local ventilation path and the benefits of secondary recirculation disappear during cooling, when the local parallel fans are off ( $E_r = 0.0$ ).

An example of this in an IDF context is shown:

```
DesignSpecification:ZoneAirDistribution,  
  CM DSZAD ZN_1_FLR_1_SEC_1,  !- Name  
  1,                          !- Zone Air Distribution Effectiveness in Cooling Mode {dimensionless}  
  1,                          !- Zone Air Distribution Effectiveness in Heating Mode {dimensionless}  
  ;                            !- Zone Air Distribution Effectiveness Schedule Name
```

### 1.17.4 Sizing:Parameters

This object allows the user to specify global heating and cooling sizing ratios. These ratios will be applied at the zone level to all of the zone heating and cooling loads and air flow rates. These new loads and air flow rates are then used to calculate the system level flow rates and capacities and are used in all component sizing calculations.

The user can also specify the width (in load timesteps) of a moving average window which can be used to smooth the calculated zone design flow sequences. The use of this parameter is described below.

#### 1.17.4.1 Field: Heating Sizing Factor

The global heating sizing ratio applied to all of the zone design heating loads and air flow rates.

#### 1.17.4.2 Field: Cooling Sizing Factor

The global cooling sizing ratio applied to all of the zone design cooling loads and air flow rates

#### 1.17.4.3 Field: Timesteps in Averaging Window

The number of load timesteps in the zone design flow sequence averaging window. The default is 1, in which case the calculated zone design flow rates are averaged over the load timestep.

The zone design air flow rate calculation is performed assuming a potentially infinite supply of heating or cooling air at a fixed temperature. Thus the calculated design air flow rate will always be able to meet any load or change in load no matter how large or abrupt. In reality air flow rates are limited by duct sizes and fan

capacities. The idealized zone design flow calculation may result in unrealistically large flow rates, especially if the user is performing the sizing calculations using thermostat schedules with night setup or setback. The calculated zone design flow rates are always averaged over the load timestep. The user may want to perform a broader average to mitigate the effect of thermostat setup and setback and prevent the warm up or cool down flow rates from dominating the design flow rate calculation.. Specifying the width of the averaging window allows the user to do this.

For example, if the load calculation timestep is 15 minutes and the user specifies the *Timesteps in Averaging Window* to be 4, the zone design air flows will be averaged over a time period of 1 hour. Specifying 8 would result in averaging over a 2 hour period.

### 1.17.5 Sizing Parameters Outputs

The sizing factors and the averaging window size are reported out on the *eplusout.eio* file. An example is:

```
! <Load Timesteps in Zone Design Calculation Averaging Window>, Value
Timesteps in Averaging Window, 1
! <Heating Sizing Factor Information>, Sizing Factor ID, Value
Heating Sizing Factor, Global, 1.3000
Heating Sizing Factor, Zone SPACE1-1, 1.3000
Heating Sizing Factor, Zone SPACE2-1, 1.3000
Heating Sizing Factor, Zone SPACE3-1, 1.3000
Heating Sizing Factor, Zone SPACE4-1, 1.3000
Heating Sizing Factor, Zone SPACE5-1, 1.3000
! <Cooling Sizing Factor Information>, Sizing Factor ID, Value
Cooling Sizing Factor, Global, 1.3000
Cooling Sizing Factor, Zone SPACE1-1, 1.3000
Cooling Sizing Factor, Zone SPACE2-1, 1.3000
Cooling Sizing Factor, Zone SPACE3-1, 1.3000
Cooling Sizing Factor, Zone SPACE4-1, 1.3000
Cooling Sizing Factor, Zone SPACE5-1, 1.3000
```

### 1.17.6 OutputControl:Sizing:Style

As described early in the document (see: EnergyPlus Output Processing), the user may select the "style" for the sizing result files (*epluszsz.<ext>*, *eplussz.<ext>*). This object applies to all sizing output files.

```
OutputControl:Sizing:Style,
  \memo default style for the Sizing output files is comma -- this works well for
  \memo importing into spreadsheet programs such as Excel(tm) but not so well for word
  \memo processing programs -- there tab may be a better choice. fixed puts spaces between
  \memo the "columns"
  \unique-object
A1; \field Column Separator
  \required-field
  \type choice
  \key Comma
  \key Tab
  \key Fixed
```

#### 1.17.6.1 Field: Column Separator

For this field, the desired separator for columns is entered. "Comma" creates comma separated fields/columns in the outputs (*eplus<sizing type>.csv* files are created). "Tab" creates tab separated fields/columns in the outputs (*eplus<sizing type>.tab* files are created). "Fixed" creates space separated fields/columns in the outputs (*eplus<sizing type>.txt* files are created) but these are not necessarily lined up for easy printing.

Note that both tab and comma separated files easily import into Excel™ or other spreadsheet programs. The tab delimited files can also be viewed by text editors, word processing programs and easily converted to "tables" within those programs.

### 1.17.7 Sizing:Zone

The Sizing:Zone object provides the data needed to perform a zone design air flow calculation for a single zone. This calculation assumes a variable amount of supply air at a fixed temperature and humidity. The information needed consists of the zone inlet supply air conditions: temperature and humidity ratio for heating and cooling. The calculation is done for every design day included in the input. The maximum cooling load and air flow and the maximum heating load and air flow are then saved for the system level design calculations and for the component automatic sizing calculations.

The Sizing:Zone object is also the place where the user can specify the design outdoor air flow rate by referencing the name of a design specification outdoor air object. This can be specified in a number of ways (ref. *DesignSpecification:OutdoorAir*). This data is saved for use in the system sizing calculation or for sizing zone components that use outdoor air.

The user can also place limits on the heating and design cooling air flow rates. See *Heating Design Air Flow Method* and *Cooling Design Air Flow Method* below and the explanations of the various heating and cooling flow input fields.

The user can ask the zone design calculation to take into account the effect of a Dedicated Outdoor Air System on the zone design loads and airflow rates. The design calculation will calculate the heat addition rate to the zone of an idealized SOA system and add or subtract the result from the total zone loads and flow rates.

#### 1.17.7.1 Field: Zone Name

The name of the Zone corresponding to this Sizing:Zone object. This is the zone for which the design air flow calculation will be made using the input data of this Sizing:Zone Object.

#### 1.17.7.2 Field: Zone Cooling Design Supply Air Temperature Input Method

The input must be either *SupplyAirTemperature* or *TemperatureDifference*. *SupplyAirTemperature* means that the user inputs from the fields of Zone Cooling Design Supply Air Temperature will be used to determine the zone cooling design air flow rates. *TemperatureDifference* means that the user inputs from the fields of Zone Cooling Design Supply Air Temperature Difference will be used to determine the zone cooling design air flow rates.

#### 1.17.7.3 Field: Zone Cooling Design Supply Air Temperature

The supply air temperature in degrees Celsius for the zone cooling design air flow rate calculation. Air is supplied to the zone at this temperature during the cooling design day simulation, The zone load is met by varying the zone air flow rate. The maximum zone flow rate is saved as the zone cooling design air flow rate. This field is only used when Zone Cooling Design Supply Air Temperature Input Method = **SupplyAirTemperature**.

#### 1.17.7.4 Field: Zone Cooling Design Supply Air Temperature Difference

The temperature difference between cooling design supply air temperature and room air temperature in degrees Celsius for the zone cooling design air flow rate calculation. Air is supplied to the zone at this temperature during the cooling design day simulation. The zone load is met by varying the zone air flow rate. The maximum zone flow rate is saved as the zone cooling design air flow rate. This field is only used when Zone Cooling Design Supply Air Temperature Input Method = **TemperatureDifference**.

#### 1.17.7.5 Field: Zone Heating Design Supply Air Temperature Input Method

The input must be either *SupplyAirTemperature* or *TemperatureDifference*. *SupplyAirTemperature* means that the user inputs from the fields of Zone Heating Design Supply Air Temperature will be used to determine the zone heating design air flow rates. *TemperatureDifference* means that the user inputs from the fields of Zone Heating Design Supply Air Temperature Difference will be used to determine the zone heating design air flow rates.

#### 1.17.7.6 Field: Zone Heating Design Supply Air Temperature

The supply air temperature in degrees Celsius for the zone heating design air flow rate calculation. Air is supplied to the zone at this temperature during the heating design day simulation, The zone load is met by varying the zone air flow rate. The maximum zone flow rate is saved as the zone heating design air flow rate. This field is only used when Zone Heating Design Supply Air Temperature Input Method = **SupplyAirTemperature**.

#### 1.17.7.7 Field: Zone Heating Design Supply Air Temperature Difference

The temperature difference between heating design supply air temperature and room air temperature in degrees Celsius for the zone heating design air flow rate calculation. Air is supplied to the zone at this temperature during the heating design day simulation. The zone load is met by varying the zone air flow rate. The maximum zone flow rate is saved as the zone heating design air flow rate. This field is only used when Zone Heating Design Supply Air Temperature Input Method = **TemperatureDifference**.

#### 1.17.7.8 Field: Zone Cooling Design Supply Air Humidity Ratio

The humidity ratio in kilograms of water per kilogram of dry air of the supply air in the zone cooling design air flow rate calculation.

#### 1.17.7.9 Field: Zone Heating Design Supply Air Humidity Ratio

The humidity ratio in kilograms of water per kilogram of dry air of the supply air in the zone heating design air flow rate calculation.

#### 1.17.7.10 Field: Design Specification Outdoor Air Object Name

This alpha field specifies the name of a DesignSpecification:OutdoorAir object which specifies the design outdoor air flow rate for the zone.

#### 1.17.7.11 Field: Zone Heating Sizing Factor

This input is a zone level heating sizing ratio. The zone design heating air flow rates and loads will be multiplied by the number input in this field. This input overrides the building level sizing factor input in the Sizing:Parameters object. And, of course, if this field is blank or zero, the global heating sizing factor from the Sizing:Parameters object is used.

#### 1.17.7.12 Field: Zone Cooling Sizing Factor

This input is a zone level cooling sizing ratio. The zone design cooling air flow rates and loads will be multiplied by the number input in this field. This input overrides the building level sizing factor input in the Sizing:Parameters object. And, of course, if this field is blank or zero, the global cooling sizing factor from the Sizing:Parameters object is used.

#### 1.17.7.13 Field: Cooling Design Air Flow Method

The input must be either *Flow/Zone*, *DesignDay*, or *DesignDayWithLimit*. *Flow/Zone* means that the program will use the input of the field *Cooling Design Air Flow Rate* as the zone design cooling air flow rate. *DesignDay* means the program will calculate the zone design cooling air flow rate using the *Sizing:Zone* input data and a design day simulation without imposing any limits other than those set by the minimum outside air requirements. *DesignDayWithLimit* means that the maximum from *Cooling Minimum Air Flow per Zone Floor Area* and *Cooling Minimum Air Flow* will set a lower limit on the design maximum cooling air flow rate. The default method is *DesignDay*: i.e., the program uses the calculated design values subject to ventilation requirements.

#### 1.17.7.14 Field: Cooling Design Air Flow Rate

The design zone cooling air flow rate in cubic meters per second. This input is used if *Cooling Design Air Flow Method* is specified as *Flow/Zone*. This value will be multiplied by the global or zone sizing factor and by zone multipliers.

#### 1.17.7.15 Field: Cooling Minimum Air Flow per Zone Floor Area

The minimum zone cooling volumetric flow rate per square meter (units are  $\text{m}^3/\text{s}\cdot\text{m}^2$ ). This field is used when *Cooling Design Air Flow Method* is specified as *DesignDayWithLimit*. In this case it sets a lower bound on the zone design cooling air flow rate. In all cases the maximum flow derived from *Cooling Minimum Air Flow per Zone Floor Area*, *Cooling Minimum Air Flow*, and *Cooling Minimum Air Flow Fraction* is used to set a minimum supply air flow rate for the zone for VAV systems. The default is .000762, corresponding to .15 cfm/ft<sup>2</sup>. The applicable sizing factor is not applied to this value.

#### 1.17.7.16 Field: Cooling Minimum Air Flow

The minimum zone cooling volumetric flow rate in  $\text{m}^3/\text{s}$ . This field is used when *Cooling Design Air Flow Method* is specified as *DesignDayWithLimit*. In this case it sets a lower bound on the zone design cooling air flow rate. In all cases the maximum flow derived from *Cooling Minimum Air Flow per Zone Floor Area*, *Cooling Minimum Air Flow*, and *Cooling Minimum Air Flow Fraction* is used to set a minimum supply air flow rate for the zone for VAV systems. The default is zero. The applicable sizing factor is not applied to this value.

#### 1.17.7.17 Field: Cooling Minimum Air Flow Fraction

The minimum zone design cooling volumetric flow rate expressed as a fraction of the zone design cooling volumetric flow rate. . In all cases the maximum flow derived from *Cooling Minimum Air Flow per Zone Floor Area*, *Cooling Minimum Air Flow*, and *Cooling Minimum Air Flow Fraction* is used to set a minimum supply air flow rate for the zone for VAV systems. The default is zero. This input is currently used in sizing the fan minimum flow rate. It does not currently affect other component autosizing.

#### 1.17.7.18 Field: Heating Design Air Flow Method

The input must be either *Flow/Zone*, *DesignDay*, or *DesignDayWithLimit*. *Flow/Zone* means that the program will use the input of the field *Heating Design Air Flow Rate* as the zone design heating air flow rate. *DesignDay* means the program will calculate the zone design heating air flow rate using the *Sizing:Zone* input data and a design day simulation without imposing any limits other than those set by the minimum outside air requirements. *DesignDayWithLimit* means that the maximum from *Heating Maximum Air Flow per Zone Floor Area* and *Heating Maximum Air Flow* will set a lower limit on the design maximum heating air flow rate. The default method is *DesignDay*: i.e., the program uses the calculated design values subject to ventilation requirements.

#### 1.17.7.19 Field: Heating Design Air Flow Rate

The design zone heating air flow rate in cubic meters per second. This input is used if *Heating Design Air Flow Method* is specified as *Flow/Zone*. This value will be multiplied by the global or zone sizing factor and by zone multipliers.

#### 1.17.7.20 Field: Heating Maximum Air Flow per Zone Floor Area

The maximum zone heating volumetric flow rate per square meter (units are  $\text{m}^3/\text{s}\cdot\text{m}^2$ ). This field is used when *Heating Design Air Flow Method* is specified as *DesignDayWithLimit*. In this case it sets an upper bound on the zone design heating air flow rate. For this and the next two input fields, the maximum flow derived from *Heating Maximum Air Flow per Zone Floor Area*, *Heating Maximum Air Flow*, and *Heating Maximum Air Flow Fraction* is used to set a maximum heating supply air flow rate for the zone for VAV systems. The default is .002032, corresponding to .40 cfm/ft<sup>2</sup>. If the maximum heating design flow rate calculated using these input fields is greater than the design heating flow rate calculated during sizing, these input fields have no impact on sizing. It may be more appropriate to select only one of these three fields to calculate the maximum heating design flow rate (i.e., if one or more of these three fields is 0, it will not be used in calculating the maximum heating design flow rate).

#### 1.17.7.21 Field: Heating Maximum Air Flow

The maximum zone heating volumetric flow rate in  $\text{m}^3/\text{s}$ . This field is used when *Heating Design Air Flow Method* is specified as *DesignDayWithLimit*. In this case it sets an upper bound on the zone design heating air flow rate. For this field and the two input fields just prior to and after this field, the maximum flow derived from *Heating Maximum Air Flow per Zone Floor Area*, *Heating Maximum Air Flow*, and *Heating Maximum Air Flow Fraction* is used to set a maximum heating supply air flow rate for the zone for VAV systems. The default is .1415762, corresponding to 300 cfm. If the maximum heating design flow rate calculated using these input fields is greater than the design heating flow rate calculated during sizing, these input fields have no impact on sizing. It may be more appropriate to select only one of these three fields to calculate the maximum heating design flow rate (i.e., if one or more of these three fields is 0, it will not be

used in calculating the maximum heating design flow rate).

#### 1.17.7.22 Field: Heating Maximum Air Flow Fraction

The maximum zone design heating volumetric flow rate expressed as a fraction of the zone design cooling volumetric flow rate. For this and the previous two input fields, the maximum flow derived from *Heating Maximum Air Flow per Zone Floor Area*, *Heating Maximum Air Flow*, and *Heating Maximum Air Flow Fraction* is used to set a maximum heating supply air flow rate for the zone for VAV systems. The default is 0.3. If the maximum heating design flow rate calculated using these input fields is greater than the design heating flow rate calculated during sizing, these input fields have no impact on sizing. It may be more appropriate to select only one of these three fields to calculate the maximum heating design flow rate (i.e., if one or more of these three fields is 0, it will not be used in calculating the maximum heating design flow rate).

#### 1.17.7.23 Field: Design Specification Zone Air Distribution Object Name

The name of the DesignSpecification:ZoneAirDistribution object, defining the air distribution effectiveness and secondary recirculation air fraction, that applies to the zone or zone list. This object may be used for the same zone in the Controller:MechanicalVentilation object if no such DesignSpecification:ZoneAirDistribution object is specified.

#### 1.17.7.24 Field: Account for Dedicated Outdoor Air System

This is a choice field with choices *Yes* or *No*. The default is *No*. Choosing *Yes* means that the zone sizing calculation will use the subsequent inputs to calculate the heat gain or loss (heat gains are positive, heat loss is negative) imposed on the zone by a Dedicated Outdoor Air System (DOAS). This heat gain is then added to the zone design heat gain for the zone and the zone design air flow rate is adjusted to meet the DOAS heat gain plus the zone design heat gain.

#### 1.17.7.25 Field: Dedicated Outdoor Air System Control Strategy

This is a choice field with a choice of three ideal control strategies for the DOA system. The choices are *NeutralSupplyAir*, *NeutralDehumidifiedSupplyAir*, or *ColdSupplyAir*. The default is *NeutralSupplyAir*.

*NeutralSupplyAir* implies that the ventilation air supplied to the zone will cause little heating or cooling. The air will be heated or cooled to keep it between the low and high temperature setpoints specified in the subsequent two fields. A good choice for these fields might be 21.1 and 23.9 degrees C.

*NeutralDehumidifiedSupplyAir* means that the ventilation air will be cooled and dehumidified and then reheated to a neutral temperature. The ventilation air is cooled to the lower setpoint temperature (if necessary) and reheated to the upper setpoint temperature. A good choice for the setpoints would be 14.4 and 22.2 degrees C.

*ColdSupplyAir* means that the ventilation air will be used to supply cooling to the zone. Cold outside air is heated to the upper setpoint; warm outside air is cooled to the lower setpoint. A good choice for the setpoints would be 12.2 and 14.4 degrees C.

#### 1.17.7.26 Field: Dedicated Outdoor Air Low Temperature Setpoint for Design

The lower setpoint temperature to be used with the DOAS design control strategy. The units are degrees C. The default is autosized to the values given above for the three design control strategies.

#### 1.17.7.27 Field: Dedicated Outdoor Air High Temperature Setpoint for Design

The higher setpoint temperature to be used with the DOAS design control strategy. The units are degrees C. The default is autosized to the values given above for the three design control strategies.

### 1.17.8 Zone Sizing Outputs

The zone design air flow rates and loads are output onto the local file “epluszsz.<ext>” where <ext> is the extension from the sizing style object (default is csv – a comma separated file *epluszsz.csv*). The columns are clearly labeled. It will easily import into Excel or other spreadsheet program that accepts delimited files. All of these values are design air flow rates and loads *calculated by the program*. No sizing factors have been applied.

The calculated zone design air flow rates and the user input or altered zone design air flow rates are also reported on the *eplusout.eio* file. The values are printed out for each zone as comma separated records beginning with *Zone Sizing*. Items output on the *eio* file are: zone name, load type (heating or cooling), design load, calculated design air flow rate, user design air flow rate, design day name, time of peak, outside temperature at peak, outside humidity ratio at peak.

### 1.17.9 DesignSpecification:ZoneHVAC:Sizing

This object is used to describe general sizing and scalable sizing methods which are referenced by zone HVAC equipment objects. It is optional input field in zone HVAC objects. If a name of this optional input is not specified or is blank then the sizing method or input specified in the parent object is used. If the name of this object is entered, then the values or method specified overrides the sizing method in the parent zone HVAC objects. This object is meant to provide scalable sizing method to users. The name of this object is an optional input field in the zoneHVAC objects. When this name is not specified in the zone HVAC object the sizing method or the value specified in the zone HVAC object will be used.

List of zoneHVAC objects than can reference this object include:

- ZoneHVAC:TerminalUnit:VariableRefrigerantFlow
- ZoneHVAC:PackagedTerminalAirConditioner
- ZoneHVAC:PackagedTerminalHeatPump
- ZoneHVAC:WaterToAirHeatPump
- ZoneHVAC:WindowAirConditioner
- ZoneHVAC:UnitHeater
- ZoneHVAC:UnitVentilator
- ZoneHVAC:FourPipeFanCoil
- ZoneHVAC:VentilatedSlab
- ZoneHVAC:EvaporativeCoolerUnit
- ZoneHVAC:IdealLoadsAirSystem

The sizing methods input fields available in this objects are for supply air flow and capacity for heating and cooling operating modes. Some zone HVAC equipment has single supply air flow rate input field that serves both cooling and heating operating modes. So entering either of the cooling or heating scalable sizing input field is sufficient. When there are separate input fields for cooling, heating, no-cooling, and no-heating operating modes, the corresponding input fields are specified. The child components supply air flow rate are also sized using scalable sizing methods specified in the parent objects. The methods allow users to enter a fixed or hard sized values, autosizable, or scalable sizing methods. Methods allowed for sizing supply air flow rates include: *SupplyAirFlowRate*, *FractionOfAutosizedCoolingAirflow*, *FractionOfAutosizedHeatingAirflow*, *FlowPerFloorArea*, *FlowPerCoolingCapacity*, and *FlowPerHeatingCapacity*. The different sizing options are defined as follows:

- **SupplyAirFlowRate**: entered when it is intended that the user specified either hard value or the simulation engine autosize the supply air flow rates for cooling, heating, and no-cooling or no-heating operating modes.

- **FlowPerFloorArea:** entered when it is intended that the simulation engine determine the supply air flow rates from the user specified *supply air flow rates per unit floor area* and the zone floor area of the zone served by the zone HVAC equipment.
- **FractionOfAutosizedCoolingAirflow:** entered when it is intended that the simulation engine determines the supply air flow rates from the user specified *flow fraction* and *autosized cooling design supply air flow rate*.
- **FractionOfAutosizedHeatingAirflow:** entered when it is intended that the simulation engine determines the supply air flow rates from the user specified *flow fraction* and *autosized heating design supply air flow rate*.
- **FlowPerCoolingCapacity:** entered when it is intended t that he simulation engine determines the supply air flow rates from the user specified *supply air flow per cooling capacity value* and *autosized cooling design capacity*.
- **FlowPerHeatingCapacity:** entered when it is intended that the simulation engine determines the supply air flow rates from the user specified *supply air flow per heating capacity value* and *autosized heating design capacity*.

The Design Specification ZoneHVAC Sizing object also has input fields for sizing or scalable sizing of cooling and heating capacity. However, most of the parent zone HVAC objects do not have input fields for sizing capacities. So, the capacity scalable sizing fields in the parent objects are used for sizing child components capacity sizings. The scalable capacity sizing may be indirectly impacted by the scalable supply air flow rates sizing values. Moreover, the autosized cold water, hot water and steam flow rates in the parent zone HVAC objects (e.g. FanCoils, UnitHeaters, UnitVentilators, and VentilatedSlabs) and capacity in child components are determined using the scalable sizing methods. Sizing methods allowed for cooling and heating capacity include: *CoolingDesignCapacity*, *HeatingDesignCapacity*, *CapacityPerFloorArea*, *FractionOfAutosizedCoolingCapacity*, *FractionOfAutosizedHeatingCapacity*.

- **CoolingDesignCapacity:** entered when it is intended that user specifies either a hard sized cooling capacity value or the simulation engine autosizes cooling capacity value for the cooling design capacity.
- **HeatingDesignCapacity:** entered when it is intended that user specifies either a hard sized heating capacity value or the simulation engine autosized heating capacity value for the heating design capacity.
- **CapacityPerFloorArea:** is entered when it is intended that the simulation engine determines the cooling or heating capacity from user specified capacity per floor area value and the floor area of the zone served by the zone HVAC equipment.
- **FractionOfAutosizedCoolingCapacity:** entered when it is intended that the simulation engine sizes the cooling capacity from the user specified *capacity fraction* and *autosized cooling design capacity* value.
- **FractionOfAutosizedHeatingCapacity:** entered when it is intended that the simulation engine sizes the heating capacity from the user specified *capacity fraction* and *autosized heating design capacity* value.

Description of the input fields of the design specification zone HVAC sizing object "DesignSpecification:ZoneHVAC:Sizing":

#### 1.17.9.1 Field: Name

Unique identifier name of the DesignSpecification:ZoneHVAC:Sizing object. This sizing specification object referenced by a zone HVAC equipment whose design calculation will be made using the input data of this object.

#### 1.17.9.2 Field: Cooling Design Air Flow Method

The input of this field must be the method used to determine the cooling supply air volume flow rate. Input allowed is either *None*, *SupplyAirFlowRate*, *FlowPerFloorArea*, *FractionOfAutosizedCoolingAirflow*, or *FlowPerCoolingCapacity*. *None* means cooling coil is not included in the zone HVAC equipment or this field may be left blank. *SupplyAirFlowRate* means the user specifies the magnitude of supply air flow rate or the program calculates the design cooling supply air volume flow rate if autosize is specified. *FlowPerFloorArea* means the program calculates the cooling supply air volume flow rate from zone floor area served by the zone HVAC unit and user specified *Flow Per Floor Area* value. *FractionOfAutosizedCoolingAirflow* means the program calculates the cooling supply air volume flow rate from user specified fraction and the autosized design cooling supply air volume flow rate value determined by the simulation. *FlowPerCoolingCapacity* means the supply air volume is calculated from user specified flow per cooling capacity and design cooling capacity determined by the simulation. The default method is *SupplyAirFlowRate*.

#### 1.17.9.3 Field: Cooling Design Supply Air Flow Rate {m3/s}

Enter the magnitude of the cooling supply air volume flow rate in m3/s. This input is an alternative to using the program auto-calculated value. This input is a required field when the Cooling Design air Flow Method is *SupplyAirFlowRate*. This field may be left blank if a cooling coil is not included in the zone HVAC equipment. This input field is also autosizable.

#### 1.17.9.4 Field: Cooling Design Supply Air Flow Rate Per Floor Area {m3/s-m2}

Enter the cooling supply air volume flow rate per zone conditioned floor area in m3/s-m2. This field is required field when the Cooling Design air Flow Method is *FlowPerFloorArea*. This field may be left blank if a cooling coil is not included in the zone HVAC equipment or the Cooling Design Air Flow Method is not *FlowPerFloorArea*. The program calculates the cooling supply air volume flow rate from the zone conditioned floor area served by the zone HVAC equipment and the flow per unit area value specified by the user. Zone sizing object (Sizing:Zone) is not required.

#### 1.17.9.5 Field: Fraction of Autosized Cooling Design Supply Air Flow Rate {-}

Enter the cooling supply air volume flow rate as a fraction of the autosized cooling supply air flow rate. This input field is required when the Cooling Design air Flow Method is *FractionOfAutosizedCoolingAirflow*. This input field may be left blank if a cooling coil is not included in the zone HVAC equipment or the Cooling Design air Flow Method is not *FractionOfAutosizedCoolingAirflow*. The program calculates the cooling supply air volume flow rate from the design autosized cooling supply air flow rate and user specified fraction. Zone sizing object (Sizing:Zone) is required.

#### 1.17.9.6 Field: Cooling Design Supply Air Flow Rate Per Unit Cooling Capacity {m3/s-W}

Enter the cooling supply air volume flow rate per unit cooling capacity in m3/s-W. This input field is required when the Cooling Design air Flow Method is *FlowPerCoolingCapacity*. This field may be left blank if a cooling coil is not included in the zone HVAC equipment or the Cooling Design air Flow Method is not *FlowPerCoolingCapacity*. The program calculates the cooling supply air volume flow rate from the design autosized cooling capacity and user specified flow per cooling capacity value. Zone sizing object (Sizing:Zone) is required.

#### 1.17.9.7 Field: Supply Air Flow Rate Method When No Cooling or Heating is Required

Enter the method used to determine the supply air volume flow rate when No Cooling or Heating is required. Inputs allowed are *None*, *SupplyAirFlowRate*, *FlowPerFloorArea*, *FractionOfAutosizedCoolingAirflow*, and *FractionOfAutosizedHeatingAirflow*. *None* is used when a cooling or heating coil is not included in the zone HVAC equipment or this field may be left blank. *SupplyAirFlowRate* means user specifies the magnitude of supply air flow rate or the program calculates the design supply air volume flow rate if autosize is specified. *FlowPerFloorArea* means the program calculates the supply air volume flow rate from the zone floor area served by the zone HVAC unit and Flow Per Floor Area value specified by user. *FractionOfAutosizedCoolingAirflow* means the program calculates the supply air volume flow rate from user specified fraction and autosized design cooling supply air volume flow rate value determined by the program. *FractionOfAutosizedHeatingAirflow* means the program calculates the supply air volume flow rate from user specified fraction and autosized heating supply air flow rate value determined by the program. The default method is *SupplyAirFlowRate*.

#### 1.17.9.8 Field: Supply Air Flow Rate When No Cooling or Heating is Required {m3/s}

Enter the magnitude of the supply air volume flow rate when no cooling or heating is required in m3/s. This input is an alternative to using the program auto-calculated value. This input is a required field when the Supply Air Flow Rate Method When No Cooling or Heating is Required is *SupplyAirFlowRate*. This field may be left blank if a cooling coil is not included in the zone HVAC equipment. This input field is also autosizable.

#### 1.17.9.9 Field: Supply Air Flow Rate Per Floor Area When No Clg or Htg is Required {m3/s-m2}

Enter the magnitude of supply air volume flow rate per zone floor area in m3/s-m2. This input is a required field when Supply Air Flow Rate Method When No Cooling or Heating is Required is *FlowPerFloorArea*. The program calculates the supply air flow rate when no cooling or heating is required from user specified flow per floor area and the zone area served by current zoneHVAC equipment.

#### 1.17.9.10 Field: Fraction of Design Cooling Supply Air Flow Rate When No Clg or Htg Required {-}

Enter the fraction of supply air volume flow rate as a fraction of the autosized cooling supply air flow rate. This input field is required field when Supply Air Flow Rate Method When No Cooling or Heating is Required is *FractionOfAutosizedCoolingAirflow*. The program calculates the supply air flow rate when no cooling or heating is required from user specified fraction and the design cooling autosized supply air flow rate.

#### 1.17.9.11 Field: Fraction of Design Heating Supply Air Flow Rate When No Clg or Htg Required {-}

Enter the fraction of supply air volume flow rate as a fraction of the autosized cooling supply air flow rate. This input field is required field when Supply Air Flow Rate Method When No Cooling or Heating is Required is *FractionOfAutosizedHeatingAirflow*. The program calculates the supply air flow rate when no cooling or heating is required from user specified fraction and the design heating autosized supply air flow rate.

#### 1.17.9.12 Field: Heating Design Air Flow Method

The input of this field must be the method used to determine the heating supply air volume flow rate. Input allowed is either *None*, *SupplyAirFlowRate*, *FlowPerFloorArea*, *FractionOfAutosizedCoolingAirflow*, or *FlowPerCoolingCapacity*. *None* means heating coil is not included in the zone HVAC equipment or this field may be left blank. *SupplyAirFlowRate* means the user specifies the magnitude of supply air flow rate or the program calculates the design heating supply air volume flow rate if autosize is specified. *FlowPerFloorArea* means the program calculates the heating supply air volume flow rate from zone floor area served by the zone HVAC unit and user specified Flow Per Floor Area value. *FractionOfAutosizedHeatingAirflow* means the program calculates the heating supply air volume flow rate from user specified fraction and the autosized design heating supply air volume flow rate value determined by the simulation. *FlowPerHeatingCapacity* means the supply air volume is calculated from user specified flow per heating capacity and design heating capacity determined by the simulation. The default method is *SupplyAirFlowRate*.

#### 1.17.9.13 Field: Heating Design Supply Air Flow Rate {m3/s}

Enter the magnitude of the heating supply air volume flow rate in m3/s. This input is an alternative to using the program auto-calculated value. This input is a required field when the Heating Design air Flow Method is *SupplyAirFlowRate*. This field may be left blank if a heating coil is not included in the zone HVAC equipment. This input field is also autosizable.

#### 1.17.9.14 Field: Heating Design Supply Air Flow Rate Per Floor Area {m3/s-m2}

Enter the heating supply air volume flow rate per zone conditioned floor area in m3/s-m2. This field is required field when the Heating Design air Flow Method is *FlowPerFloorArea*. This field may be left blank if a heating coil is not included in the zone HVAC equipment or the Heating Design Air Flow Method is not *FlowPerFloorArea*. The program calculates the heating supply air volume flow rate from the zone conditioned floor area served by the zone HVAC equipment and the flow per unit area value specified by the user.

#### 1.17.9.15 Field: Fraction of Autosized Heating Design Supply Air Flow Rate {-}

Enter the heating supply air volume flow rate as a fraction of the autosized heating supply air flow rate. This input field is required when the Heating Design air Flow Method is *FractionOfAutosizedHeatingAirflow*. This input field may be left blank if a heating coil is not included in the zone HVAC equipment or the Heating Design air Flow Method is not *FractionOfAutosizedHeatingAirflow*. The program calculates the heating supply air volume flow rate from the design autosized heating supply air flow rate and user specified fraction.

#### 1.17.9.16 Field: Heating Design Supply Air Flow Rate Per Unit Heating Capacity {m3/s-W}

Enter the heating supply air volume flow rate per unit heating capacity in m3/s-W. This input field is required when the Heating Design air Flow Method is *FlowPerHeatingCapacity*. This field may be left blank if a cooling coil is not included in the zone HVAC equipment or the Heating Design air Flow Method is not *FlowPerHeatingCapacity*. The program calculates the heating supply air volume flow rate from the design autosized heating capacity and user specified flow per unit heating capacity value.

#### 1.17.9.17 Field Cooling Design Capacity Method

Enter the method used to determine the cooling design capacity for scalable sizing. Input allowed is either *None*, *CoolingDesignCapacity*, *CapacityPerFloorArea*, and *FractionOfAutosizedCoolingCapacity*. *None* is used when a cooling coil is not included in the Zone HVAC equipment or this field may be left blank. If this input field is left blank, then the design cooling capacity is set to zero. *CoolingDesignCapacity* means user specifies the magnitude of cooling capacity or the program calculates the design cooling capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design cooling capacity from user specified cooling capacity per floor area and floor area of the zone served by the HVAC unit. *FractionOfAutosizedCoolingCapacity* means the program calculates the design cooling capacity from user specified fraction and the auto-sized design cooling capacity. The default method is *CoolingDesignCapacity*.

#### 1.17.9.18 Field: Cooling Design Capacity {W}

Enter the magnitude of the cooling capacity in Watts. This input is an alternative to using the program auto-calculated cooling capacity value. This input is a required field when the Cooling Design Capacity Method is *CoolingDesignCapacity*. This field may be left blank if a cooling coil is not included in the zone HVAC equipment or alternative method is specified. This input field is autosizable. Design day sizing run must be specified.

#### 1.17.9.19 Field: Cooling Design Capacity Per Floor Area {W/m2}

Enter the cooling capacity per unit floor area in m3/s-m2. This field is required field when the Cooling Design Capacity Method is *CapacityPerFloorArea*. This field may be left blank if a cooling coil is not included in the zone HVAC equipment or the Cooling Design Capacity Method is not *CapacityPerFloorArea*. The program calculates the cooling capacity from floor area of the zone served by the zone HVAC equipment and the cooling capacity per unit floor area value specified by the user.

#### 1.17.9.20 Field: Fraction of Autosized Cooling Design Capacity {-}

Enter the cooling capacity as a fraction of the autosized cooling capacity. This input field is required when the Cooling Design Capacity Method is *FractionOfAutosizedCoolingCapacity*. This input field may be left blank if a cooling coil is not included in the zone HVAC equipment or the Cooling Design Capacity Method is not *FractionOfAutosizedCoolingCapacity*. The program calculates the cooling capacity from the design autosized cooling capacity and user specified fraction. Design day sizing run must be specified.

#### 1.17.9.21 Field: Heating Design Capacity Method

Enter the method used to determine the heating design capacity for scalable sizing. Input allowed is either *None*, *HeatingDesignCapacity*, *CapacityPerFloorArea*, and *FractionOfAutosizedHeatingCapacity*. *None* is used when a heating coil is not included in the Zone HVAC equipment or this field may be left blank. If this input field is left blank, then the design heating capacity is set to zero. *HeatingDesignCapacity* means user specifies the magnitude of heating capacity or the program calculates the design heating capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design heating capacity from user specified heating capacity per floor area and floor area of the zone served by the HVAC unit. *FractionOfAutosizedHeatingCapacity* means the program calculates the design heating capacity from user specified fraction and the auto-sized design heating capacity. The default method is *HeatingDesignCapacity*.

#### 1.17.9.22 Field: Heating Design Capacity {W}

Enter the magnitude of the heating capacity in Watts. This input is an alternative to using the program auto-calculated heating capacity value. This input is a required field when the Heating Design Capacity Method is *HeatingDesignCapacity*. This field may be left blank if a heating coil is not included in the zone HVAC equipment or alternative method is specified. This input field is autosizable. Design day sizing run must be specified.

#### 1.17.9.23 Field: Heating Design Capacity Per Floor Area {W/m2}

Enter the heating capacity per unit floor area in m3/s-m2. This field is required field when the Heating Design Capacity Method is *CapacityPerFloorArea*. This field may be left blank if a heating coil is not included in the zone HVAC equipment or the Heating Design Capacity Method is not *CapacityPerFloorArea*. The program calculates the heating capacity from floor area of the zone served by the zone HVAC equipment and the heating capacity per unit floor area value specified by the user.

#### 1.17.9.24 Field: Fraction of Autosized Heating Design Capacity {-}

Enter the heating capacity as a fraction of the autosized heating capacity. This input field is required when the Heating Design Capacity Method is *FractionOfAutosizedHeatingCapacity*. This input field may be left blank if a heating coil is not included in the zone HVAC equipment or the Heating Design Capacity Method is not *FractionOfAutosizedHeatingCapacity*. The program calculates the heating capacity from the design autosized cooling capacity and user specified fraction. Design day sizing run must be specified.

## 1.17.10 Sizing:System

The Sizing:System object contains the input needed to perform a central forced air system design air flow, heating capacity, and cooling capacity calculation for a system serving one or more zones. The information needed consists of the outside environmental conditions and the design supply air temperatures, outdoor air flow rate, and minimum system air flow ratio.

The outside conditions come from the design days in the input. A system sizing calculation is performed for every design day in the input file and the resulting maximum heating and cooling air flow rates and capacities are saved for use in the component sizing calculations.

Supply air conditions are specified by inputting a supply air temperature for cooling, a supply air temperature for heating, and a preheat temperature.

The system sizing calculation sums the zone design air flow rates to obtain a system supply air flow rate. The design conditions and the outdoor air flow rate are used to calculate a design mixed air temperature. The temperature plus the design supply air temperatures allows the calculation of system design heating and cooling capacities.

### 1.17.10.1 Field: AirLoop Name

The name of the AirLoopHVAC corresponding to this Sizing:System object. This is the air system for which the design calculation will be made using the input data of this Sizing:System Object.

### 1.17.10.2 Field: Type of Load to Size On

The user specified type of load on which to size the central system. The choices are *Sensible*, *Total* and *VentilationRequirement*. *Sensible* means that the central system supply air flow rate will be determined by combining the zone design air flow rates, which have been calculated to meet the zone sensible loads from the design days. *VentilationRequirement* means that the central system supply air flow rate will be determined by the system ventilation requirement. In addition *Sensible* tells the program to size the central cooling coil using entering air flow rate and air conditions at the sensible load peak; *Total* indicates that the program should size the central cooling coil at the air flow rate and conditions at the total load peak. The central heating coil is always sized at the conditions at the peak sensible heating load.

### 1.17.10.3 Field: Design Outdoor Air Flow Rate

The design outdoor air flow rate in cubic meters per second. Generally this should be the minimum outdoor air flow. It is used for both heating and cooling design calculations. The assumption for cooling is that any outdoor air economizer will be closed. If *Autosize* is input the outdoor air flow rate will be taken from the sum of the zone outdoor air flow rates or calculated based on the System Outdoor Air Method selection (field below).

#### 1.17.10.4 Field: Central Heating Maximum System Air Flow Ratio

The ratio of the maximum system air flow rate for heating to the maximum system air flow rate. The value must be between 0 and 1. For constant volume systems the ratio should be set to 1. This ratio should be set to reflect what the user expects the system flow rate to be when maximum heating demand occurs. This ratio is used in calculating the central system heating capacity. Thus if the system is VAV with the zone VAV dampers held at minimum flow when there is a zone heating demand, this ratio should be set to the minimum flow ratio. If the zone VAV dampers are reverse action and can open to full flow to meet heating demand, this ratio should be set to 1. The default is set to 0.5, reflecting the fact that VAV dampers are typically not allowed to fully open during heating.

#### 1.17.10.5 Field: Preheat Design Temperature

The design air temperature exiting the preheat coil (if any) in degrees Celsius.

#### 1.17.10.6 Field: Preheat Design Humidity Ratio

The design humidity ratio exiting the preheat coil (if any) in kilograms of water per kilogram of dry air. (kgWater/kgDryAir)

#### 1.17.10.7 Field: Precool Design Temperature

The design air temperature exiting the precooling coil (if any) in degrees Celsius.

#### 1.17.10.8 Field: Precool Design Humidity Ratio

The design humidity ratio exiting the precooling coil (if any) in kilograms of water per kilogram of dry air. (kgWater/kgDryAir)

#### 1.17.10.9 Field: Central Cooling Design Supply Air Temperature

The design supply air temperature for cooling in degrees Celsius. This should be the temperature of the air exiting the central cooling coil.

#### 1.17.10.10 Field: Central Heating Design Supply Air Temperature

The design supply air temperature for heating in degrees Celsius. This can be either the reset temperature for a single duct system or the actual hot duct supply air temperature for dual duct systems. It should be the temperature at the exit of the main heating coil.

#### 1.17.10.11 Field: Type of Zone Sum to Use

If the input is *coincident* the central system air flow rate will be sized on the sum of the coincident zone air flow rates. If the input is *noncoincident* the central system air flow rate will be sized on the sum of the noncoincident zone air flow rates. The default is noncoincident.

#### 1.17.10.12 Field: 100% Outdoor Air in Cooling

Entering *Yes* means the system will be sized for cooling using 100% outdoor air. Entering *No* means the system will be sized for cooling using minimum outside air (the default).

#### 1.17.10.13 Field: 100% Outdoor Air in Heating

Entering *Yes* means the system will be sized for heating using 100% outdoor air. Entering *No* means the system will be sized for heating using minimum outside air (the default).

#### 1.17.10.14 Field: Central Cooling Design Supply Air Humidity Ratio

The design humidity ratio in kilograms of water per kilogram of dry air at the exit of the central cooling coil. (kgWater/kgDryAir) The default is .008.

#### 1.17.10.15 Field: Central Heating Design Supply Air Humidity Ratio

The design humidity ratio in kilograms of water per kilogram of dry air at the exit of the central heating coil. (kgWater/kgDryAir) The default is .008.

#### 1.17.10.16 Field: Cooling Supply Air Flow Rate Method

The input of this field must be the method used to determine the airloop cooling supply air volume flow rate. The input must be either *DesignDay*, *Flow/System*, *FlowPerFloorArea*, *FractionOfAutosizedCoolingAirflow*, or *FlowPerCoolingCapacity*. *DesignDay* means the program will calculate the system design cooling supply air volume flow rate using the System Sizing input data and a design day simulation. *Flow/System* means that the program will use the input of the field *Cooling Design Air Flow Rate* as the system design cooling supply air volume flow rate. *FlowPerFloorArea* means the program calculates the cooling supply air volume flow rate from zone floor area served by the airloop and user specified *Flow Per Floor Area* value. *FractionOfAutosizedCoolingAirflow* means the program calculates the cooling supply air volume flow rate from user specified fraction and the autosized design cooling supply air volume flow rate value determined by the simulation. *FlowPerCoolingCapacity* means the supply air volume is calculated from user specified flow per cooling capacity and design cooling capacity determined by the simulation. The default method is *DesignDay*: i.e., the program uses the calculated design values.

#### 1.17.10.17 Field: Cooling Supply Air Flow Rate

The design system cooling air flow rate in cubic meters per second. This input is an alternative to using the program autocalculated value. This input is used if Cooling Supply Air Flow Rate Method is Flow/System. This value will *not* be multiplied by any sizing factor or by zone multipliers. If using zone multipliers, this value must be large enough to serve the multiplied zones.

#### 1.17.10.18 Field: Cooling Supply Air Flow Rate Per Floor Area {m3/s-m2}

Enter the cooling supply air volume flow rate per zone conditioned floor area in m3/s-m2. This field is required field when the Cooling Supply Air Flow Rate Method is *FlowPerFloorArea*. This field may be left blank if a cooling coil is not included in the airloop or the Cooling Supply Air Flow Rate Method is not *FlowPerFloorArea*. The program calculates the cooling supply air volume flow rate from the cooled floor area served by the air loop and the *Flow Per Unit Area* value specified by the user.

#### 1.17.10.19 Field: Cooling Fraction of Autosized Cooling Design Supply Air Flow Rate {-}

Enter the cooling supply air volume flow rate as a fraction of the airloop autosized cooling supply air flow rate. This input field is required when the Cooling Supply Air Flow Rate Method is *FractionOfAutosizedCoolingAirflow*. This input field may be left blank if a cooling coil is not included in the airloop or the Cooling Supply Air Flow Rate Method is not *FractionOfAutosizedCoolingAirflow*. The program calculates the cooling supply air volume flow rate from the design autosized cooling supply air flow rate and user specified fraction.

#### 1.17.10.20 Field: Cooling Supply Air Flow Rate Per Unit Cooling Capacity {m3/s-W}

Enter the cooling supply air volume flow rate per unit cooling capacity in m3/s-W. This input field is required when the Cooling Supply Air Flow Rate Method is *FlowPerCoolingCapacity*. This field may be left blank if a cooling coil is not included in the airloop or the Cooling Supply Air Flow Rate Method is not *FlowPerCoolingCapacity*. The program calculates the airloop cooling supply air volume flow rate from the design autosized cooling capacity and user specified *Flow Per Cooling Capacity* value.

#### 1.17.10.21 Field: Heating Supply Air Flow Rate Method

The input of this field must be the method used to determine the airloop heating supply air volume flow rate. The input must be either *DesignDay*, *Flow/System*, *FlowPerFloorArea*, *FractionOfAutosizedHeatingAirflow*, *FractionOfAutosizedCoolingAirflow* or *FlowPerHeatingCapacity*. *DesignDay* means the program will calculate the system design heating supply air volume flow rate using the System Sizing input data and a design day simulation. *Flow/System* means that the program will use the input of the field *Heating Design Air Flow Rate* as the system design heating supply air volume flow rate. *FlowPerFloorArea* means the program calculates the system heating supply air volume flow rate from zone floor area served by the airloop and user specified *Flow Per Floor Area* value. *FractionOfAutosizedHeatingAirflow* means the program calculates the system heating supply air volume flow rate from user specified fraction and the autosized system design heating supply air volume flow rate value determined by the simulation. *FractionOfAutosizedCoolingAirflow* means the program calculates the system heating supply air volume flow rate from user specified fraction and the autosized system design cooling supply air volume flow rate value determined by the simulation. *FlowPerHeatingCapacity* means the system heating supply air volume is calculated from user specified flow per heating capacity and design heating capacity determined by the simulation. The default method is *DesignDay*: i.e., the program uses the calculated design values.

#### 1.17.10.22 Field: Heating Supply Air Flow Rate

The design system heating air flow rate in cubic meters per second. This input is an alternative to using the program autocalculated value. This input is used if Heating Supply Air Flow Rate Method is Flow/System. This value will *not* be multiplied by any sizing factor or by zone multipliers. If using zone multipliers, this value must be large enough to serve the multiplied zones.

#### 1.17.10.23 Field: Heating Supply Air Flow Rate Per Floor Area {m3/s-m2}

Enter the heating supply air volume flow rate per zone conditioned floor area in m3/s-m2. This field is required field when the Heating Supply Air Flow Rate Method is *FlowPerFloorArea*. This field may be left blank if a heating coil is not included in the airloop or the Heating Supply Air Flow Rate Method is not *FlowPerFloorArea*. The program calculates the heating supply air volume flow rate from the heated or cooled floor area served by the air loop and the *Flow Per Unit Area* value specified by the user.

#### 1.17.10.24 Field: Heating Fraction of Autosized Heating Supply Air Flow Rate {-}

Enter the heating supply air volume flow rate as a fraction of the airloop autosized heating supply air flow rate. This input field is required when the Heating Supply Air Flow Rate Method is *FractionOfAutosizedHeatingAirflow*. This input field may be left blank if heating coil is not included in the airloop or the Heating Supply Air Flow Rate Method is not *FractionOfAutosizedHeatingAirflow*. The program calculates the heating supply air volume flow rate from the design autosized heating supply air flow rate and user specified fraction.

#### 1.17.10.25 Field: Heating Fraction of Autosized Cooling Supply Air Flow Rate {-}

Enter the heating supply air volume flow rate as a fraction of the airloop autosized cooling supply air flow rate. This input field is required when the Heating Supply Air Flow Rate Method is *FractionOfAutosizedCoolingAirflow*. This input field may be left blank if heating coil is not included in the airloop or the Heating Supply Air Flow Rate Method is not *FractionOfAutosizedCoolingAirflow*. The program calculates the heating supply air volume flow rate from the design autosized cooling supply air flow rate and user specified fraction.

#### 1.17.10.26 Field: Heating Design Supply Air Flow Rate Per Unit Heating Capacity {m3/s-W}

Enter the heating supply air volume flow rate per unit heating capacity in m3/s-W. This input field is required when the Heating Design air Flow Method is *FlowPerCoolingCapacity*. This field may be left blank if a heating coil is not included in the airloop or the Heating Design air Flow Method is not *FlowPerHeatingCapacity*. The program calculates the airloop heating supply air volume flow rate from the design autosized heating capacity and user specified *Flow Per Heating Capacity* value.

#### 1.17.10.27 Field: System Outdoor Air Method

The method used to calculate the system minimum outdoor air flow. The two choices are *ZoneSum* and *VentilationRateProcedure (VRP)*. *ZoneSum* sums the outdoor air flows across all zones served by the system. *VRP* uses the multi-zone equations defined in 62.1-2007 to calculate the system outdoor air flow. *VRP* considers zone air distribution effectiveness and zone diversification of outdoor air fractions.

#### 1.17.10.28 Field: Zone Maximum Outdoor Air Fraction

This positive numeric input is the zone maximum outdoor air fraction. For an air loop, when a zone requires outdoor air higher than the user specified *Zone Maximum Outdoor Air Fraction*, the zone supply air flow will be increased to cap the outdoor air fraction at the maximum value. This allows the system level outdoor air flow to be reduced while the total supply air flow increases. Valid values are from 0 to 1.0. Default is 1.0 which indicates zones can have 100% outdoor air maintaining backward compatibility. This inputs work for constant volume air systems, single and dual duct VAV systems.

#### 1.17.10.29 Field Cooling Design Capacity Method

Enter the method used to determine the cooling design capacity for scalable sizing. Input allowed is either *None*, *CoolingDesignCapacity*, *CapacityPerFloorArea*, and *FractionOfAutosizedCoolingCapacity*. *None* is used when a cooling coil is not included in the airloop. If this input field is left blank, or *None* is specified, then the autosized design cooling capacity determined by the program is used. *CoolingDesignCapacity* means user specifies the magnitude of cooling capacity or the program calculates the design cooling capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design cooling capacity from user specified cooling capacity per floor area and floor area of the zones served by the airloop. *FractionOfAutosizedCoolingCapacity* means the program calculates the design cooling capacity from user specified fraction and the auto-sized design cooling capacity. If the value this input field is blank or specified as *None*, then the next three input fields are not required. The default method is *CoolingDesignCapacity*.

#### 1.17.10.30 Field: Cooling Design Capacity {W}

Enter the magnitude of the cooling capacity in Watts. This input is an alternative to using the program auto-calculated cooling capacity value. This input is a required field when the Cooling Design Capacity Method is *CoolingDesignCapacity*. This field may be left blank if a cooling coil is not included in the air loop or alternative method is specified. This input field is autosizable.

#### 1.17.10.31 Field: Cooling Design Capacity Per Floor Area {W/m2}

Enter the cooling capacity per unit floor area in m3/s-m2. This field is required field when the Cooling Design Capacity Method is *CapacityPerFloorArea*. This field may be left blank if a cooling coil is not included in the airloop or the Cooling Design Capacity Method is not *CapacityPerFloorArea*. The program calculates the cooling capacity from floor area of the zones served by the airloop and the cooling capacity per unit floor area value specified by the user.

#### 1.17.10.32 Field: Fraction of Autosized Cooling Design Capacity {-}

Enter the cooling capacity as a fraction of the autosized cooling capacity. This input field is required when the Cooling Design Capacity Method is *FractionOfAutosizedCoolingCapacity*. This input field may be left blank if a cooling coil is not included in the zone HVAC equipment or the Cooling Design Capacity Method is not *FractionOfAutosizedCoolingCapacity*. The program calculates the cooling capacity from the design autosized cooling capacity and user specified fraction. Design day sizing run must be specified.

#### 1.17.10.33 Field: Heating Design Capacity Method

Enter the method used to determine the heating design capacity for scalable sizing. Input allowed is either *None*, *HeatingDesignCapacity*, *CapacityPerFloorArea*, and *FractionOfAutosizedHeatingCapacity*. *None* is used when a heating coil is not included in the airloop. If this input field is left blank, then the autosized design heating capacity determined by the program is used. *HeatingDesignCapacity* means user specifies the magnitude of heating capacity or the program calculates the design heating capacity if autosize is specified. *CapacityPerFloorArea* means the program calculates the design heating capacity from user specified heating capacity per floor area and floor area of the zones served by the airloop. *FractionOfAutosizedHeatingCapacity* means the program calculates the design heating capacity from user specified fraction and the auto-sized design heating capacity. If the value this input field is blank or specified as *None*, then the next three input fields are not required. The default method is *HeatingDesignCapacity*.

#### 1.17.10.34 Field: Heating Design Capacity {W}

Enter the magnitude of the heating capacity in Watts. This input is an alternative to using the program auto-calculated heating capacity value. This input is a required field when the Heating Design Capacity Method is *HeatingDesignCapacity*. This field may be left blank if a heating coil is not included in the airloop or alternative method is specified. This input field is autosizable.

#### 1.17.10.35 Field: Heating Design Capacity Per Floor Area {W/m2}

Enter the heating capacity per unit floor area in m3/s-m2. This field is required field when the Heating Design Capacity Method is *CapacityPerFloorArea*. This field may be left blank if a heating coil is not included in the airloop or the Heating Design Capacity Method is not *CapacityPerFloorArea*. The program calculates the heating capacity from floor area of the zones served by the airloop and the heating capacity per unit floor area value specified by the user.

#### 1.17.10.36 Field: Fraction of Autosized Heating Design Capacity {-}

Enter the heating capacity as a fraction of the autosized heating capacity. This input field is required when the Heating Design Capacity Method is *FractionOfAutosizedHeatingCapacity*. This input field may be left blank if heating coil is not included in the airloop or the Heating Design Capacity Method is not *FractionOfAutosizedHeatingCapacity*. The program calculates the heating capacity from the design autosized cooling capacity and user specified fraction.

#### 1.17.10.37 Field: Central Cooling Capacity Control Method

Specifies how the central cooling coil will be controlled, which affects the coil sizing calculation. There are 4 choices: VAV, Bypass, VT, and OnOff. Choose VAV if the cooling output is controlled by varying the air flow. Bypass should be chosen if the capacity is controlled by bypassing a variable fraction of the mixed air around the coil face. VT indicates that cooling coil output is controlled by varying the coil exit temperature while the flow rate is constant. And OnOff means that the cooling output is controlled by cycling the air flow.

An IDF example:

```
Sizing:System,

    ;                  !- Fraction of Autosized Cooling Design Capacity {-}
```

#### 1.17.11 System Sizing Outputs

The system design air flow rates and heating and cooling capacities are output onto the local file "eplussz.<ext>" where <ext> is the extension from the sizing style object (default is csv – a comma separated file *eplussz.csv*). The columns are clearly labeled. It will easily import into Excel or other spreadsheet program that accepts delimited files. The results are calculated values and do not include any user input system flow rates.

The calculated system design air flow rates and the user input system design air flow rates are also reported on the *eplusout.eio* file. The values are printed out for each system as comma separated records beginning with *System Sizing*. An example is:

```
! <System Sizing Information>c++, System Name, Field Description, Value
System Sizing, VAV SYS 1, Calculated Cooling Design Air Flow Rate [m3/s], 1.3194
System Sizing, VAV SYS 1, User Cooling Design Air Flow Rate [m3/s], 1.5000
System Sizing, VAV SYS 1, Calculated Heating Design Air Flow Rate [m3/s], 0.90363
System Sizing, VAV SYS 1, User Heating Design Air Flow Rate [m3/s], 1.0000
```

#### 1.17.12 Sizing:Plant

The Sizing:Plant object contains the input needed for the program to calculate plant loop flow rates and equipment capacities when autosizing. This information

is initially used by components that use water for heating or cooling such as hot or chilled water coils to calculate their maximum water flow rates. These flow rates are then summed for use in calculating the Plant Loop flow rates.

The program will size any number of chilled water, hot water, condenser water and other plant loops. There should be one Sizing:Plant object for each plant loop that is to be autosized.

#### 1.17.12.1 Field: Plant or Condenser Loop Name

The name of a Plant Loop or Condenser Loop object corresponding to this Sizing:Plant object. This is the plant loop for which this data will be used for calculating the loop flow rate.

#### 1.17.12.2 Field: Loop Type

The possible inputs are *Heating, Steam, Cooling, or Condenser*.

#### 1.17.12.3 Field: Design Loop Exit Temperature

The water temperature in degrees Celsius at the exit of the supply side of the plant loop, Thus this is the temperature of the water supplied to the inlet of chilled or hot water coils and other equipment that places loads on a plant loop.

#### 1.17.12.4 Field: Loop Design Temperature Difference

The design temperature rise (for cooling or condenser loops) or fall (for heating loops) in degrees Celsius across the demand side of a plant loop. This temperature difference is used by component models to determine flow rates required to meet design capacities. Larger values lead to smaller design flow rates.

#### 1.17.12.5 Field: Sizing Option

This field is optional. This field controls how concurrence issues impact the plant loop design flow rate. If it is not used then the program uses noncoincident method, which is the historical behavior prior to version 8.3. There are two choices, noncoincident and coincident. The use of Coincident sizing option requires that the SimulationControl object be set to YES for the input field called Do HVAC Sizing Simulation for Sizing Periods.

#### 1.17.12.6 Field: Zone Timesteps in Averaging Window

This field is optional and is only used if the preceding field is set to Coincident. This is the number of zone timesteps used in a moving average to determine the design flow rate from HVAC Sizing Simulation approach. This allows using a broader average over time when using coincident plant sizing. This is similar in concept to the similar field in Sizing:Parameters which specifies the averaging window for zone loads. The default is 1.

#### 1.17.12.7 Field: Coincident Sizing Factor Mode

This field is only used if the sizing option is set to Coincident. This field controls the behavior of coincident sizing with respect to what, if any, sizing factor should be applied to further modify the flow rate measured while running HVAC Sizing Simulations. There are four options. Enter the keyword None to use the raw value for flow rate without modification. Enter the keyword GlobalHeatingSizingFactor to modify the flow by the sizing factor entered in the object called Sizing:Parameters for heating. Enter the keyword GlobalCoolingSizingFactor to modify the flow by the sizing factor entered in the object called Sizing:Parameters for cooling. Enter the keyword LoopComponentSizingFactor to modify the flow by a sizing factor determined from the combination of component-level sizing factors in the associated plant loop.

An IDF example:

```
Sizing:Plant,
  Chilled Water Loop, ! name of loop
  Cooling,           ! type of loop
  7.22,              ! chilled water supply temperature
  6.67,              ! chilled water delta T
  NonCoincident,    !- Sizing Option
  1,                  !- Zone Timesteps in Averaging Window
  GlobalCoolingSizingFactor; !- Coincident Sizing Factor Mode
```

### 1.17.13 Plant Sizing Outputs

The loop flow rates are reported on the *eplusout.eio* file along with the component sizing results.

When coincident plant sizing method is used, the *eio* file contains special summary report with various details and interim values from the calculations, under the following record header: !, Plant Loop Name, Sizing Pass {#}, Measured Mass Flow{kg/s}, Measured Demand {W}, Demand Calculated Mass Flow{kg/s}, Sizes Changed {Yes/No}, Previous Volume Flow Rate {m3/s}, New Volume Flow Rate {m3/s}, Demand Check Applied {Yes/No}, Sizing Factor {}, Normalized Change {}, Specific Heat{}

## 1.18 HVAC: Primary and Secondary Systems

The HVAC and equipment section of the EnergyPlus input data dictionary and input data file are slightly more complex than the description of building geometry, internal gains, etc. because of the interconnections of the various parts of an HVAC system. In EnergyPlus, there are several portions to the HVAC simulation. All of these parts must be correctly specified in order to arrive at a valid simulation model. The goal of this section is to provide interface developers and advanced users with guidelines on what input is expected and also provide some background on basic EnergyPlus simulation methodology.

An EnergyPlus HVAC simulation consists of various components that are connected physically in the actual system by ducts, piping, etc. Every component in an HVAC system must have an inlet and outlet “node”. In the actual system, a node might be a point in the system at which fluid properties can be measured. In an EnergyPlus simulation, the nodes are points at which fluid properties are evaluated and passed on to subsequent equipment.

Components are linked together to form various loops within the simulation. Thus, the output node from one component also serves as the inlet node to the next component. Loops are constructed by defining these loops and also defining the components on the loops. The figure below shows a generic example of the loop-node concept.

Loop nodes are a key defining feature in EnergyPlus. As a result, it is recommended that one of the first steps taken in defining an HVAC system in EnergyPlus be the definition of a node diagram or map. This is helpful for visualization of the entire system. Such a map could be created electronically within an interface or could be kept in the background out of the sight of the user.

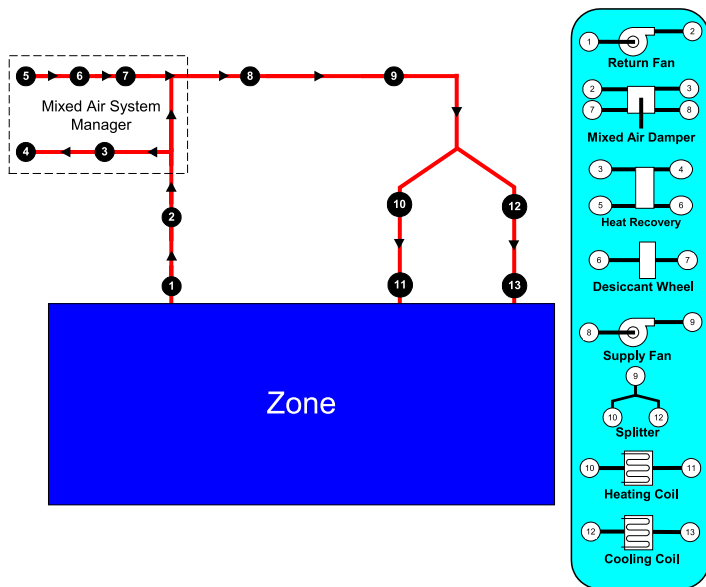

Figure 72. Example Node Diagram

So that these loops are manageable and more clearly defined both in the input and in the simulation, four different loop sections can be defined in an EnergyPlus input file. In general, these four types are in essence two pairs of loop sections that make up two distinct types of loops: a zone/air loop and a plant loop. As of Version 7, plant loops and condenser loops have been consolidated to be largely the same. The four loop section types are defined below.

**Air Loop Supply Side:** The air loop is defined by the section of the zone/air loop that starts after the zone return streams are combined and continues on until just before any air stream(s) are branched off to individual zones. The starting point of the air loop is fairly straightforward. The ending point is slightly more complex but can be understood with some examples. For instance, in a terminal reheat system, the end of the air loop would typically be considered the node following the cooling coil. In a dual duct system, the air loop would have two ending points that would correspond to the nodes after the cooling coil and after the heating coil/humidifier. In most cases, the air loop has a single starting point and up to two ending points (for a 2 deck system). An outdoor air subsystem can be included in the supply side for ventilation and relief air.

**Air Loop Zone Equipment:** The zone equipment section of the input file is defined as more or less the rest of the zone/air loop (outside air is handled separately as a subset of the air loop). This includes everything from where the ducts are split to serve various zones up through where the return ducts from various zones are mixed into a single return duct. Zone equipment can include dampers and reheat coils as well as zone specific conditioning systems such as thermostatic baseboard or a window air conditioner. Most control issues are typically dealt with in the zone equipment section of the simulation.

**Plant Loop Demand Side:** One side of the plant is where energy is “demanded” by various components that make up the air loop or zone equipment. Typically, this is the water side of equipment such as coils, baseboard, radiant heating and cooling, etc. In the case of a condenser loop, energy is typically “demanded” by a chiller condenser or other water source heat pump. The demand side of this loop can also include mixers, flow splitters, and a bypass.

**Plant Loop Supply Side:** The other side of the plant loop is where energy is “supplied” by various components. The components typically found on the supply side include pumps, boilers, chillers, purchased heating and cooling, ice storage, etc. In the case of a condenser, the components would be cooling tower, fluid cooler, or ground source heat exchanger, etc. As with the demand side, this loop can also include mixers, flow splitters, and a bypass.

The section of the input file for describing the HVAC system tends to follow this structure presented above. Both plant and condenser loops are defined with a master description and then branch off into supply and demand side details. Linkage between the two sides is done using node names in the master statement. The air loop and zone equipment descriptions are slightly more complex due to the wide range of potential systems that are anticipated. Note that in every section controls become a key element and must be addressed. Each of the following sections details either a loop, a portion of a loop, or controls.

## 1.19 Group – Node-Branch Management

**Nodes**, **Branch Lists** and **Branches** define the topography of the HVAC connections.

### 1.19.1 NodeList

For convenience, the NodeList object can be used to identify all the nodes for a particular use. A node list is not always required. The advantage of listing all the nodes in this manner is that input fields in other objects that ask for a node name can refer to either a single node or a list of nodes using this object. .

There are other lines of input syntax that require the use of a NodeList as part of the input. These syntax items include: OutdoorAir:NodeList and the SetpointManager objects. In these two cases, the use of a NodeList statement is mandatory if there is more than one node in this particular “list”. For example, if the outside air only has a single inlet node, then the name of that node can replace the node list name in the input syntax. As a result of this mandatory specification of node lists for certain types of input, nodes can, obviously, and may be members of more than one list.

#### 1.19.1.1 Field: Name

This alpha designation must be unique among all the Node List Names. It is used as reference in various objects (e.g. OutdoorAir:NodeList).

#### 1.19.1.2 Field: Node <#> Name (up to 25 allowed)

Each unique Node identifier creates a Node structure with various attributes depending on the type of node. Typical values include Temperature, Mass Flow Rate, and Temperature Set Point. The alpha designators are associated with a particular node.

Though each NodeList is limited to 25 nodes, several node lists may be entered if you choose to identify all the nodes up front. For example:

```
NodeList, Nodes1-25,  
NODE_1,NODE_2,NODE_3,NODE_4,NODE_5,NODE_6,NODE_7,NODE_8,NODE_9,NODE_10,  
NODE_11,NODE_12,NODE_13,NODE_14,NODE_15,NODE_16,NODE_17,NODE_18,NODE_19,NODE_20,  
NODE_21,NODE_22,NODE_23,NODE_24,NODE_25;  
NodeList, Nodes26-49,NODE_26,NODE_27,NODE_28,NODE_29,NODE_30,  
NODE_31,NODE_32,NODE_33,NODE_34,NODE_35,NODE_36,NODE_37,NODE_38,NODE_39,NODE_40,  
NODE_41,NODE_42,NODE_43,NODE_44,NODE_45,NODE_46,NODE_47,NODE_48,NODE_49;
```

### 1.19.2 Node List Outputs

A simple detail of Nodes and numbers assigned appears in the `plusout.bnd` file:

```
! <Node>,<NodeNumber>,<Node Name>,<Node Fluid Type>,<#\# Times Node Referenced After Definition>  
Node,1,OUTSIDE AIR INLET NODE 1,Air,2  
Node,2,VAV SYS 1 INLET NODE,Air,3  
Node,3,MIXED AIR NODE 1,Air,5  
Node,4,MAIN COOLING COIL 1 OUTLET NODE,Air,3  
Node,5,MAIN HEATING COIL 1 OUTLET NODE,Air,4  
Node,6,VAV SYS 1 OUTLET NODE,Air,7
```

In addition, properties of each node is available during the simulation:

- HVAC,Average,System Node Temperature [C]
- HVAC,Average,System Node Last Timestep Temperature [C]
- HVAC,Average,System Node Mass Flow Rate [kg/s]
- HVAC,Average,System Node Humidity Ratio [kgWater/kgDryAir]
- HVAC,Average,System Node Setpoint Temperature [C]
- HVAC,Average,System Node Setpoint High Temperature [C]
- HVAC,Average,System Node Setpoint Low Temperature [C]
- HVAC,Average,System Node Setpoint Humidity Ratio [kgWater/kgDryAir]
- HVAC,Average,System Node Setpoint Minimum Humidity Ratio [kgWater/kgDryAir]
- HVAC,Average,System Node Setpoint Maximum Humidity Ratio [kgWater/kgDryAir]
- HVAC,Average,System Node Relative Humidity [%]
- HVAC,Average,System Node Pressure [Pa]
- HVAC,Average,System Node Standard Density Volume Flow Rate [m3/s]
- HVAC,Average,System Node Enthalpy [J/kg]

- HVAC,Average,System Node Last Timestep Enthalpy [J/kg]
- HVAC,Average,System Node Wetbulb Temperature [C]
- HVAC,Average,System Node Dewpoint Temperature [C]
- HVAC,Average,System Node Quality []
- HVAC,Average,System Node Height [m]

**The following node variable is also available for system nodes that are for “air”:**

- HVAC, Average, System Node Current Density Volume Flow Rate [m3/s]
- HVAC, Average, System Node Current Density [kg/m3]

**The following node variables are “advanced” and normally used for debugging unusual cases:**

- HVAC,Average,System Node Minimum Temperature [C]
- HVAC,Average,System Node Maximum Temperature [C]
- HVAC,Average,System Node Minimum Limit Mass Flow Rate [kg/s]
- HVAC,Average,System Node Maximum Limit Mass Flow Rate [kg/s]
- HVAC,Average,System Node Minimum Available Mass Flow Rate [kg/s]
- HVAC,Average,System Node Maximum Available Mass Flow Rate [kg/s]
- HVAC,Average,System Node Requested Mass Flow Rate [kg/s]
- HVAC,Average,System Node Setpoint Mass Flow Rate [kg/s]

**The following node variable reports node carbon dioxide concentration when carbon dioxide is simulated (ref. ZoneAirContaminantBalance):**

- HVAC,Average,System Node CO2 Concentration [ppm]

**The following node variable reports node generic contaminant concentration when generic contaminant is simulated (ref. ZoneAirContaminantBalance):**

- HVAC,Average,System Node Generic Air Contaminant Concentration [ppm]

#### **1.19.2.1 System Node Temperature [C]**

The current temperature at a system node in degrees C. For air nodes, this is the dry-bulb temperature.

#### **1.19.2.2 System Node Last Timestep Temperature [C]**

The temperature at a system node for the previous timestep.

#### **1.19.2.3 System Node Mass Flow Rate [kg/s]**

The current mass flow rate at a system node in kg/s.

#### **1.19.2.4 System Node Humidity Ratio [kgWater/kgDryAir]**

The current humidity ratio at a system node in kg-water/kg-dry-air. Not applicable for liquid nodes.

#### **1.19.2.5 System Node Setpoint Temperature [C]**

The current setpoint temperature at a system node in degrees C. Some controllers and equipment types sense this single setpoint.

#### **1.19.2.6 System Node Setpoint High Temperature [C]**

The current upper setpoint temperature at a system node in degrees C. Some controllers and equipment types use dual setpoints at a single node.

#### **1.19.2.7 System Node Setpoint Low Temperature [C]**

The current lower setpoint temperature at a system node in degrees C. Some controllers and equipment types use dual setpoints at a single node.

#### **1.19.2.8 System Node Setpoint Humidity Ratio [kgWater/kgDryAir]**

The current humidity ratio setpoint at a system node in kg-water/kg-dry-air. Some controllers and equipment types sense this single setpoint. Not applicable for liquid nodes.

#### **1.19.2.9 System Node Setpoint Minimum Humidity Ratio [kgWater/kgDryAir]**

The current minimum desired humidity ratio at a system node in kg-water/kg-dry-air. Some controllers and equipment types use the min/max values as dual setpoints at a single node. Not applicable for liquid nodes.

#### **1.19.2.10 System Node Setpoint Maximum Humidity Ratio [kgWater/kgDryAir]**

The current maximum desired humidity ratio at a system node in kg-water/kg-dry-air. Some controllers and equipment types use the min/max values as dual setpoints at a single node. Not applicable for liquid nodes.

#### **1.19.2.11 System Node Relative Humidity [%]**

The current relative humidity (calculated from the node temperature, node humidity ratio and standard barometric pressure for the location). Not applicable for liquid nodes.

#### **1.19.2.12 System Node Pressure [Pa]**

The current pressure at a system node in Pa.

#### **1.19.2.13 System Node Standard Density Volume Flow Rate [m<sup>3</sup>/s]**

The current volume flow rate at a system node in m<sup>3</sup>/s. This report is calculated from the mass flow using standardized values for density that do not vary over time (except for steam which varies with quality). For water nodes this density is determined at a temperature of 5.05°C. For air nodes this density is determined for dry air at the standard barometric pressure for the location's elevation, and a temperature of 20.0°C. For air nodes, also see the report "System Node Current Density Volume Flow Rate."

#### **1.19.2.14 System Node Enthalpy [J/kg]**

The current enthalpy at a system node in J/kg.

#### **1.19.2.15 System Node Last Timestep Enthalpy [J/kg]**

The enthalpy at the system node for the previous timestep in Joules per kilogram.

#### **1.19.2.16 System Node Wetbulb Temperature [C]**

The current wet-bulb temperature at a system node in degrees C. Not applicable for liquid nodes.

#### **1.19.2.17 System Node Dewpoint Temperature [C]**

The current dewpoint temperature at a system node in degrees C. It is calculated from the System Node Temperature, the System Node Humidity Ratio and the Site Outdoor Air Barometric Pressure. Not applicable for liquid nodes.

#### **1.19.2.18 System Node Quality []**

The current system node vapor fraction/percent {0.0-1.0}.

#### **1.19.2.19 System Node Height [m]**

The current system node height {m}. Only applicable to outdoor air nodes.

#### **Additional Node Reporting for Air Nodes**

The following system node variable is available for nodes with a fluid type of air.

#### **1.19.2.20 System Node Current Density Volume Flow Rate [m<sup>3</sup>/s]**

The current volume flow rate at a system node in m<sup>3</sup>/s based on the current density. This report differs from the one called "System Node Standard Density Volume Flow Rate" in that it uses an air density calculated for the current moist air conditions rather than a standard density.

#### **1.19.2.21 System Node Current Density [kg/m<sup>3</sup>]**

The current air density at a system node in kg/m<sup>3</sup>. This is the density used to calculate the volume flow rate above. The density is calculated using current outdoor air barometric pressure and the drybulb temperature and humidity ratio at the air node.

## Advanced Node Reporting

The following system node variables are available when you request “Diagnostics, DisplayAdvancedReportVariable;”. They are normally used for debugging unusual system cases and may not be available for all systems. Also, their definitions may change based on the usage in the system.

### 1.19.2.22 System Node Minimum Temperature [C]

### 1.19.2.23 System Node Maximum Temperature [C]

These node variables represent the min/max of loops or branches.

### 1.19.2.24 System Node Minimum Limit Mass Flow Rate [kg/s]

### 1.19.2.25 System Node Maximum Limit Mass Flow Rate [kg/s]

These node variables hold the maximum possible and the minimum allowable flow rates for a particular component. As such, they represent the “hardware limit” on the flow rate for the component. By convention, these variables are stored at the component inlet node. Since components share their nodes (the outlet node of one component is the inlet node of the next component), the protocol must be strictly followed. These variables are set by each component based on the design flow limits of the equipment.

### 1.19.2.26 System Node Minimum Available Mass Flow Rate [kg/s]

### 1.19.2.27 System Node Maximum Available Mass Flow Rate [kg/s]

These node variables represent the *loop* or *branch* maximum and minimum flow rate for the current configuration of the loop on which the component resides. The central plant routines manage these variables dynamically to resolve flow rates through branches located inside splitters and mixers.

### 1.19.2.28 System Node Setpoint Mass Flow Rate [kg/s]

The current mass flow rate setpoint at a system node in kg/s. Some controllers and equipment types sense this single setpoint.

### 1.19.2.29 System Node Requested Mass Flow Rate [kg/s]

This output is the current mass flow rate request at a system node in kg/s. Only used for plant simulations and nodes. This is the mass flow rate “requested” by a component. This is a record of what the component wanted which can be useful for diagnostics when the actual simulated flow is different than expected. This value is also used to determine overall loop flow rates.

### 1.19.2.30 System Node CO2 Concentration [ppm]

The average carbon dioxide concentration, in parts per million (ppm), at a system node for the timestep being reported.

### 1.19.2.31 System Node Generic Air Contaminant Concentration [ppm]

The average generic contaminant concentration, in parts per million (ppm), at a system node for the timestep being reported.

## 1.19.3 BranchList

A branch list is intended to define the branches or portions of a particular loop that are present on an individual plant or condenser loop. Thus, the BranchList syntax simply provides a list of branch names (see Branch syntax) that then refer to more detailed syntax in another part of the input file. The syntax for describing a list of branches is given below.

Branches in BranchList objects should be listed in flow order: inlet branch, then parallel branches, then outlet branch. Branches (within a splitter/mixer) are simulated in the order listed.

### 1.19.3.1 Field: Name

A unique name to identify the branch list.

### 1.19.3.2 Field: Branch <#> Name

Branch name in the list. As noted above, Branches in BranchList objects MUST be listed in flow order: inlet branch, then parallel branches, then outlet branch. Branches are simulated in the order listed.

An example of this statement in an IDF is:

```
BranchList, Cooling Supply Side Branches,  
    CW Pump Branch,  
    Little Chiller Branch,  
    Big Chiller Branch,
```

Purchased Cooling Branch,  
Supply Bypass Branch,  
Cooling Supply Outlet;

## 1.19.4 Branch List Output

No output directly related to Branch Lists current is presented.

## 1.19.5 Branch

Branches can be considered the mid-level grouping of items in the EnergyPlus HVAC loop scheme. Components are the lowest level of information. A collection of components in series forms a branch. Every branch must have at least one component, but it may have several components in series. The air loop also has “unitary” objects that are compound objects that wrap components and when they are used it is the unitary objects that appear on the Branch and not the child components. The **Branch** defines the order that components appear on the branch. Moreover, a collection of branches and their connecting information form a loop. Therefore, a branch is a collection of components while a loop is a collection of branches. Thus, components are specified for particular HVAC loops by assigning them to branches and then connecting those branches together to form a loop.

For hydronic plant systems, the Branch object is used on both the demand side and the supply side of the plant loop. For HVAC air systems, the Branch object is only used to describe the components on the supply side of an air loop. The demand side of the air loop does not use the Branch object. The outside air system appears on a Branch object but it does not use a Branch object itself to describe the components that included in the outside air system. So-called “ZoneHVAC:\*” equipment, HVAC equipment directly associated with a zone, do not use the Branch object.

It should be noted that each component also has at least two nodes associated with it—an inlet node and an outlet node. These nodes, by default, are also part of the branch to which their components are assigned. Although it may appear redundant to list the node names in both the Branch and in the component object being referenced, this is needed because many components are connected to more than one loop at a time and the node names are needed here to distinguish which portion of the component is being attached to this particular branch and its loop. It should be noted that each branch must have at least one component on it. A “null” branch such as one where the first component on the loop is in reality a splitter or mixer should be defined as a single Pipe component for plant, or a single Duct component for air systems.

### 1.19.5.1 Field: Name

This alpha field is the unique, user-defined name that allows the branch to be referenced by other elements such as the PlantLoop and CondenserLoop statements.

### 1.19.5.2 Field: Maximum Flow Rate

This field is the maximum flow rate (m<sup>3</sup>/sec) allowed on a particular branch. This number will set an absolute maximum flow rate for all components on the loop. Even if components are defined with a higher flow rate, EnergyPlus will limit the flow on this particular branch to the value entered here by the user. Currently this is used in the Air Loop and is not a required field in the Plant and Condenser Loop. The example files for the Plant and Condenser Loops leave this field blank to simplify flow input.

### 1.19.5.3 Field: Pressure Drop Curve Name

This is an optional field used to specify pressure drop information for this particular branch. Currently this is only available in plant/condenser fluid loops: PlantLoop and CondenserLoop. Air loops require a full airflow network, so this field is ignored if found on an air loop. The value entered for this field must match a pressure curve object also found in the input. This curve can be of the type: Curve:Linear, Curve:Quadratic, Curve:Cubic, Curve:Exponent, or Curve:Functional:PressureDrop. In order to then perform a pressure simulation for the loop that this branch is located on, a flag must be set in the loop object. Reference the PlantLoop and CondenserLoop field “Pressure Simulation Type” for allowable settings. See the Engineering Reference document for further information on pressure simulation in plant loops.

### 1.19.5.4 Field Set (Branch Specifications)

Following the two introductory items, there are groups of 5 repeated items: a type, a name, inlet and outlet node names, and a branch control type. All of these items refer to one particular component on the branch. The first component defined by these items will be the first component on this branch, etc. through the end of the list. This object is extensible and can use as many field sets as needed.

### 1.19.5.5 Field: Component <#> Object Type

This field is the component object type (object class name). The component type refers to other elements within the input file and specifies what kind of component this is. The objects in the Group – Plant Equipment section are valid here when the Branch is used in Plant specifications. Fans, coils, unitary systems, and Outside Air Systems are also valid component types for the Branch object. Pipes or Ducts are also valid for this field. No splitter or mixer type objects are allowed.

### 1.19.5.6 Field: Component <#> Name

The component name is the unique, user-defined reference name to distinguish between potentially multiple occurrences of a particular component type in an input file. The set of component type and component name must be unique. (You can only have 1 Boiler object with name MYBOILER).

### 1.19.5.7 Field: Component <#> Inlet Node Name

This field references an inlet node name that will be found in the actual component specification. The inlet node, and the outlet node specified in the next field, should correspond to component model's connections that are intended for the loop that this Branch is assigned to. For example a water-cooled chiller will have two inlet nodes, one for chilled water return and one for condenser water return and so the chiller will appear on two Branch objects accordingly.

### 1.19.5.8 Field: Component <#> Outlet Node Name

This field references an outlet node name that will be found in the actual component specification.

### 1.19.5.9 Field: Component <#> Branch Control Type

This field is being deprecated and is no longer used or required. Prior to version 7 it was used by plant to resolve branch flow rates but now this is handled automatically by the program. The field will be removed in a future version.

An example of this statement in an IDF is:

```
Branch,
  Air Loop Main Branch,      !- Branch Name
  1.75,                      !- Maximum Branch Flow Rate {m3/s}
  ,                          !- Pressure Drop Curve Name
  AirLoopHVAC:UnitaryHeatCool:VAVChangeoverBypass, !- Comp1 Type
  GasHeat CBVAV System,     !- Comp1 Name
  Air Loop Inlet Node,      !- Comp1 Inlet Node Name
  Air Loop Outlet Node,     !- Comp1 Outlet Node Name
  ;                          !- Comp1 Branch Control Type
```

And a more complex one:

```
BRANCH,
  Air Loop Main Branch,     !- Branch Name
  1.3,                      !- Maximum Branch Flow Rate {m3/s}
  ,                          !- Pressure Drop Curve Name
  FAN:SIMPLE:ConstVolume,  !- Comp1 Type
  Supply Fan 1,            !- Comp1 Name
  Air Loop Inlet Node,     !- Comp1 Inlet Node Name
  Cooling Coil Air Inlet Node, !- Comp1 Outlet Node Name
  ,                          !- Comp1 Branch Control Type
  COIL:Water:DetailedFlatCooling, !- Comp2 Type
  Detailed Cooling Coil,   !- Comp2 Name
  Cooling Coil Air Inlet Node, !- Comp2 Inlet Node Name
  Air Loop Outlet Node,    !- Comp2 Outlet Node Name
  ;                          !- Comp2 Branch Control Type
```

## 1.19.6 Branch Output

The components on a branch are in series and that list is in simulation and connection order. Each branch must obey the rules: the outlet for component 1 has to have the same node name as the inlet for component 2, and so forth.

Eplusout.err contains the test for "individual branch integrity":

```
***** Testing Individual Branch Integrity
***** Testing Branch=AIR LOOP MAIN BRANCH
***** ...passed
***** Testing Branch=COOLING DEMAND INLET
***** ...passed
***** Testing Branch=COOLING COIL BRANCH
***** ...passed
***** Testing Branch=DEMAND BYPASS BRANCH
***** ...passed
***** Testing Branch=COOLING DEMAND OUTLET
***** ...passed
***** Testing Branch=COOLING SUPPLY OUTLET
***** ...passed
```

The addition of pressure simulation for branches in fluid loops brings a new output at the branch level:

- HVAC,Average,Plant Branch Pressure Difference [Pa]

### 1.19.6.1 Plant Branch Pressure Difference [Pa]

This field allows the user to output the pressure drop of a particular branch on a plant loop or condenser loop. This output is only recognized if a valid pressure simulation is being performed. To do this, the user must specify a pressure simulation type as an input in the PlantLoop or CondenserLoop object.

## 1.19.7 ConnectorList

A connector list is a collection of either one or two connection devices (Connector:Mixer or Connector:Splitter). Due to the definition of a loop in EnergyPlus, there is a maximum of one mixer and one splitter allowed for each loop segment. This limitation still allows a tremendous amount of flexibility to the user and can also still be solved within a reasonable amount of time and without a complex solver routine. The connection list simply allows the specification of the types and names of these devices. This allows the main loop statements to have the flexibility to have multiple lists that can have one or more item.

#### 1.19.7.1 Field: Name

This field is an identifying name that will be referenced to main loop statements using this connector list. The name must be unique among connector list names.

#### 1.19.7.2 Field-Set: Connection Object Type and Identifying Name (up to 2 allowed)

Depending on the loop, either one or two of the connectors will be specified. If this particular loop only has a single connector (either Connector:Mixer or Connector:Splitter), then only the first two items (type of connection and identifying name of connector) are included. If both a mixer and splitter are present, the additional type of connection and identifying name must be included. Note that the order that the items appear is inconsequential—either the Connector:Mixer or the Connector:Splitter may appear first. This will not affect the simulation.

#### 1.19.7.3 Field: Connector 1 Object Type

This field contains the connector type **Connector:Mixer** or **Connector:Splitter**.

#### 1.19.7.4 Field: Connector 1 Name

This field is an identifying name for the connector. It will be used by other objects in the input file.

#### 1.19.7.5 Field: Connector 2 Object Type (optional)

This field contains the connector type **Connector:Mixer** or **Connector:Splitter**.

#### 1.19.7.6 Field: Connector 2 Name (optional)

This field is an identifying name for the connector. It will be used by other objects in the input file.

An example of this statement in an IDF is:

```
ConnectorList LIST, Cooling Supply Side Connectors,  
    Connector:Splitter, CW Loop Splitter,  
    Connector:Mixer, CW Loop Mixer;
```

### 1.19.8 Connector List Outputs

No output directly related to Connector Lists is currently presented.

### 1.19.9 Pipe:Adiabatic

In reality, every component is connected to its closest neighbors via a pipe or a duct. At the current time, such detail is not needed in EnergyPlus. Thus, the Pipe:Adiabatic component is currently used more as a connection device (for branches that really do not have any components associated with them) or as a bypass than anything else. As such, its input is very simple and its algorithm is equally simple. The current algorithm for a pipe is simply to pass the inlet conditions to the outlet of the pipe component.

#### 1.19.9.1 Field: Name

This alpha field is used as an identifying field for the pipe.

#### 1.19.9.2 Field: Inlet Node Name

This alpha field is used as an identifying field for the pipe inlet node.

#### 1.19.9.3 Field: Outlet Node Name

This alpha field is used as an identifying field for the pipe outlet node.

An example of this statement in an IDF is:

```
Pipe:Adiabatic,  
    Demand Side Inlet Pipe,  
    CW Demand Inlet Node,  
    CW Demand Entrance Pipe Outlet Node;
```

### 1.19.10 Pipe Outputs

There are no outputs directly related to Pipes.

### 1.19.11 Pipe:Adiabatic:Steam

To connect the various components in a steam system regardless of it being the condensate or the steam side of the loop steam pipe needs to be used. In reality, every component is connected to its closest neighbors via a pipe or a duct. At the current time, such detail is not needed in EnergyPlus. Thus, the Pipe:Adiabatic:Steam component is currently used more as a connection device (for branches that really do not have any components associated with them). As such, its input is very simple and its algorithm is equally simple. The current algorithm for a pipe is simply to pass the inlet conditions to the outlet of the pipe component.

#### 1.19.11.1 Field: Name

This alpha field is used as an identifying field for the steam pipe.

#### 1.19.11.2 Field: Inlet Node Name

This alpha field is used as an identifying field for the steam pipe inlet node.

#### 1.19.11.3 Field: Outlet Node Name

This alpha field is used as an identifying field for the steampipe outlet node.

An example of this statement in an IDF is:

```
Pipe:Adiabatic:Steam,  
  Steam Demand 1 Steam Inlet Pipe,           !- PipeName  
  Steam Demand 1 Steam Demand Inlet Node,    !- Inlet Node Name  
  Steam Demand 1 Steam Demand Entrance Pipe Outlet Node; !- Outlet Node Name
```

### 1.19.12 Steam Pipe Outputs

There are no outputs directly related to Steam Pipes.

### 1.19.13 Pipe:Indoor

This object specifies inputs which are used to simulate the heat transfer from a plant loop pipe placed in a zone or when a user schedule is used to specify an environment.

The data definition for object is shown below.

#### 1.19.13.1 Field: Name

This alpha field is used as an identifying field for the pipe.

#### 1.19.13.2 Field: Construction Name

This alpha field references a 'wall' construction object that gives a layer-by-layer description of the pipe wall and its insulation. The construction object follows standard conventions, describing material properties for each layer beginning with the outermost insulation layer and ending with the pipe wall layer.

#### 1.19.13.3 Field: Fluid Inlet Node Name

This alpha field contains the name of the pipe fluid inlet node.

#### 1.19.13.4 Field: Fluid Outlet Node Name

This alpha field contains the name of the pipe fluid outlet node.

#### 1.19.13.5 Field: Environment Type

Environment type is the environment in which the pipe is placed. It can be either **Zone** or **Schedule**. If specified as Zone, a zone name must be specified in the next field. If specified as Schedule, the Ambient Temperature Zone can be left blank, while a schedule must be specified for the temperature and air velocity.

#### 1.19.13.6 Field: Ambient Temperature Zone Name

If **Zone** is specified as the environment type, this field is used to specify the name of the zone in which the pipe is located. The zone temperature is used to calculate the heat transfer rate from the pipe.

#### 1.19.13.7 Field: Ambient Temperature Schedule Name

If **Schedule** is specified as the environment type, this field is used to specify the name of the temperature schedule that gives the ambient air temperature surrounding the pipe. This temperature is used as the outside boundary condition to calculate heat transfer from the pipe.

#### 1.19.13.8 Field: Ambient Air Velocity Schedule Name

If **Schedule** is specified as the environment type, this field is used to specify the name of the velocity schedule that gives the air velocity near the pipe. This velocity is used to calculate the convection heat transfer coefficient used in the pipe heat transfer calculation.

#### 1.19.13.9 Field: Pipe Inside Diameter

This field is used to enter the inside diameter of the pipe in units of m. Pipe inside diameter must be a positive number.

#### 1.19.13.10 Field: Pipe Length

This field is used to enter the length of the pipe in units of m. Pipe length must be a positive number.

An example of this object in an IDF is:

```
Pipe:Indoor,
  Pipe Heat Transfer Towers,      !- name of outside panel heat exchanger
  Insulated Pipe,                !- Construction name
  Condenser Tower Outlet Node,   !- Comp1 Inlet Node Name
  HTPipe Outlet Node,           !- Comp1 Outlet Node Name
  Water,                          !- Fluid name
  Zone,                           !- field Ambient Temperature Outside Air Node name
  0.05,                           !- Pipe Inside Diameter (thickness in construction data)
  100.0;                          !- pipe length
```

### 1.19.14 Pipe:Indoor Outputs

- HVAC,Average, Pipe Fluid Heat Transfer Rate [W]
- HVAC,Average, Pipe Ambient Heat Transfer Rate [W]
- HVAC,SUM, Pipe Fluid Heat Transfer Energy [J]
- HVAC,SUM, Pipe Ambient Heat Transfer Energy [J]
- HVAC,Average, Pipe Mass Flow Rate [kg/s]
- HVAC,Average, Pipe Inlet Temperature [C]
- HVAC,Average, Pipe Outlet Temperature [C]
- HVAC,Average, Pipe Volume Flow Rate [m3/s]

#### 1.19.14.1 Pipe Fluid Heat Transfer Rate [W]

The output provides the total amount of heat loss/gain in the fluid from pipe inlet to outlet.

#### 1.19.14.2 Pipe Ambient Heat Transfer Rate [W]

The output provides the amount of heat loss/gain from pipe wall to the environment.

#### 1.19.14.3 Pipe Fluid Heat Transfer Energy [J]

Total energy fluid has lost/gained between pipe inlet and outlet. It is metered on EnergyTransfer with an end use of Pipes.

#### 1.19.14.4 Pipe Ambient Heat Transfer Energy [J]

Total energy lost from the external pipe surface.

#### 1.19.14.5 Pipe Mass Flow Rate [kg/s]

Mass flow rate of the fluid in the pipe.

#### 1.19.14.6 Pipe Inlet Temperature [C]

#### 1.19.14.7 Pipe Outlet Temperature [C]

Temperature of fluid at entering and exiting of pipe.

#### 1.19.14.8 Pipe Volume Flow Rate [m3/s]

Fluid volumetric flow rate, (mass flow rate / density)

#### 1.19.15 Pipe:Outdoor

This object specifies inputs which are used to simulate the heat transfer from a plant loop pipe placed in an outdoor environment.

##### 1.19.15.1 Field: Name

This alpha field is used as an identifying field for the pipe.

##### 1.19.15.2 Field: Construction Name

This alpha field references a 'wall' construction object that gives a layer-by-layer description of the pipe wall and its insulation. The construction object follows standard conventions, describing material properties for each layer beginning with the outermost insulation layer and ending with the pipe wall layer.

##### 1.19.15.3 Field: Fluid Inlet Node Name

This alpha field contains the name of the pipe fluid inlet node.

##### 1.19.15.4 Field: Fluid Outlet Node Name

This alpha field contains the name of the pipe fluid outlet node.

##### 1.19.15.5 Field: Ambient Temperature Outside Air Node Name

Ambient temperature outdoor air node is a node representing outdoor air with which pipe transfers heat. The node should be included in an outdoor air node list.

##### 1.19.15.6 Field: Pipe Inside Diameter

This field is used to enter the inside diameter of the pipe in units of m. Pipe inside diameter must be a positive quantity.

##### 1.19.15.7 Field: Pipe Length

This field is used to enter the length of the pipe in units of m. Pipe length must be a positive quantity.

An example of this statement in an IDF is:

```
Pipe:Outdoor,  
  Pipe Heat Transfer Towers,      !- name of outside panel heat exchanger  
  Insulated Pipe,                !- Construction name  
  Condenser Tower Outlet Node,    !- Comp1 Inlet Node Name  
  HTPipe Outlet Node,            !- Comp1 Outlet Node Name  
  Water,                         !- Fluid name  
  PipeHeatTransfer Inlet Node,    !- field Ambient Temperature Outside Air Node name  
  0.05,                          !- Pipe Inside Diameter (thickness given in construction data)  
  100.0;                          !- pipe length
```

#### 1.19.16 Pipe:Outdoor Outputs

- HVAC,Average, Pipe Fluid Heat Transfer Rate [W]
- HVAC,SUM, Pipe Fluid Heat Transfer Energy [J]
- HVAC,Average, Pipe Mass Flow Rate [kg/s]
- HVAC,Average, Pipe Inlet Temperature [T]
- HVAC,Average, Pipe Outlet Temperature [T]
- HVAC,Average, Pipe Volume Flow Rate [m3/s]

##### 1.19.16.1 Pipe Fluid Heat Transfer Rate [W]

The output provides the total amount of heat loss/gain in the fluid from pipe inlet to outlet.

##### 1.19.16.2 Pipe Fluid Heat Transfer Energy [J]

Total energy fluid has lost/gained between pipe inlet and outlet. It is metered on EnergyTransfer with an end use of Pipes.

### 1.19.16.3 Pipe Mass Flow Rate [kg/s]

Mass flow rate of the fluid in the pipe.

### 1.19.16.4 Pipe Inlet Temperature [C]

### 1.19.16.5 Pipe Outlet Temperature [C]

Temperature of fluid at entering and exiting of pipe.

### 1.19.16.6 Pipe Volume Flow Rate [m3/s]

Fluid volumetric flow rate, (mass flow rate / density)

## 1.19.17 Pipe:Underground

This object specifies inputs which are used to simulate the heat transfer from a plant loop pipe placed underground.

### 1.19.17.1 Field: Name

This alpha field is used as an identifying field for the pipe.

### 1.19.17.2 Field: Construction Name

This alpha field references a basic construction object that gives a layer-by-layer description of the pipe wall and insulation. The construction object follows standard conventions, describing material properties for each layer beginning with the outermost layer, the insulation, if it exists, and ending with the pipe wall layer. The construction object may have either one or two layers. If only one, then the material must be the pipe wall. If two, then insulation is utilized.

### 1.19.17.3 Field: Fluid Inlet Node Name

This alpha field contains the name of the pipe fluid inlet node.

### 1.19.17.4 Field: Fluid Outlet Node Name

This alpha field contains the name of the pipe fluid outlet node.

### 1.19.17.5 Field: Sun Exposure

This alpha field allows the user to specify one of two options: NoSun or SunExposed. For SunExposed, the simulation includes diffuse and beam solar effects on the ground surface. For NoSun, no solar effects are included.

### 1.19.17.6 Field: Pipe Inside Diameter

This field is used to enter the inside diameter of the pipe in units of m. Pipe inside diameter must be a positive quantity.

### 1.19.17.7 Field: Pipe Length

This field is used to enter the length of the pipe in units of {m}. Pipe length must be a positive quantity.

### 1.19.17.8 Field: Soil Material Name

This references a Material object that contains the soil properties and thickness. Note that when defining the soil layer, the thickness should be the thickness of soil between the pipe wall and the ground surface.

### 1.19.17.9 Field: Type of Undisturbed Ground Temperature Object

This is the type of undisturbed ground temperature object that is used to determine the ground temperature.

### 1.19.17.10 Field: Name of Undisturbed Ground Temperature Object

This is the name of the undisturbed ground temperature object that is used to determine the ground temperature.

An example of this object in an IDF is:

```
Pipe:Underground,  
  Pipe Heat Transfer Towers,      !- Name of Pipe  
  Insulated Buried Pipe,         !- Construction Name  
  Condenser Tower Outlet Node,   !- Inlet Node Name  
  HTPipe Outlet Node,           !- Outlet Node Name
```

```

Water,                !- Fluid Name
SunExposed,          !- Sun Exposure
0.05,               !- Pipe Inside Diameter
20.0,              !- Pipe Length
Buried Pipe Soil,   !- Soil Material
Site:GroundTemperature:Undisturbed:KusudaAchenbach, !- Type of Undisturbed Ground Temperature Object
KATemps;           !- Name of Undisturbed Ground Temperature Object

Construction,
  Insulated Buried Pipe,      !- Name
  Buried Pipe Insulation,    !- Layer #1
  Buried Pipe Steel;        !- Layer #2

Material,
  Buried Pipe Soil,         !- Name
  Smooth,                  !- Roughness
  1.5,                     !- Thickness {m}
  0.36,                   !- Conductivity {W/m-K}
  2000.0,                 !- Density {kg/m3}
  1200.0,                 !- Specific Heat {J/kg-K}
  0.9,                    !- Thermal Absorptance
  0.5,                    !- Solar Absorptance
  0.5;                    !- Visible Absorptance

```

### 1.19.18 Pipe:Underground Outputs

- HVAC, Average, Pipe Fluid Heat Transfer Rate [W]
- HVAC, SUM, Pipe Fluid Heat Transfer Energy [J]
- HVAC, Average, Pipe Mass Flow Rate [kg/s]
- HVAC, Average, Pipe Volume Flow Rate [m3/s]
- HVAC, Average, Pipe Inlet Temperature [C]
- HVAC, Average, Pipe Outlet Temperature [C]

#### 1.19.18.1 Pipe Fluid Heat Transfer Rate [W]

The output provides the total amount of heat loss/gain in the fluid from pipe inlet to outlet.

#### 1.19.18.2 Pipe Fluid Heat Transfer Energy [J]

Total energy fluid has lost/gained between pipe inlet and outlet. It is metered on

EnergyTransfer with an end use of Pipes.

#### 1.19.18.3 Pipe Mass Flow Rate [kg/s]

Mass flow rate of the fluid in the pipe.

#### 1.19.18.4 Pipe Volume Flow Rate [m3/s]

Fluid volumetric flow rate, (mass flow rate / density)

#### 1.19.18.5 Pipe Inlet Temperature [C]

#### 1.19.18.6 Pipe Outlet Temperature [C]

Temperature of fluid at entrance and exit of pipe.

### 1.19.19 PipingSystem:Underground Class Objects

Objects in this class are used to simulate the heat transfer processes of a piping system placed underground, which may or may not be in contact with a number of zone surfaces. There are three related objects, all of which are prefixed with PipingSystem:Underground :

- PipingSystem:Underground:Domain
- PipingSystem:Underground:PipeCircuit
- PipingSystem:Underground:PipeSegment

### 1.19.20 PipingSystem:Underground:Domain

This section documents the domain object, which is used to specify information for the overall ground domain, including thermal properties, mesh parameters, and surface interaction.

#### **1.19.20.1 Field: Name**

This alpha field is used as an identifying field for the ground domain.

#### **1.19.20.2 Field: XMax, YMax, ZMax**

These numeric fields are used to specify the overall domain size, in each of the three Cartesian dimensions. The domain will be meshed from  $\{x, y, z\} = \{0, 0, 0\}$  to  $\{Xmax, Ymax, Zmax\}$ .

Note that for this object, the x-z plane lies parallel to the ground surface, such that the y-dimension can be thought of as representing the burial depth. This is in contrast to the way building surface coordinates are defined with the x-y plane lying parallel to the ground. Also note that any pipe segments that end up being used in a ground domain will be placed axially in the z-dimension. Thus, pipe flow will always be in either the positive z or negative z direction.

#### **1.19.20.3 Field: X-Direction Mesh Density Parameter**

This numeric integer field represents the number of cells to be placed between any two “domain partitions” during mesh development. A domain partition may be thought of as a basement wall/floor, or a pipe. Once these components are laid out in the domain, this field number of cells are placed between the partitions. Further information on this is found in the engineering reference manual.

#### **1.19.20.4 Field: X-Direction Mesh Type**

This alpha field represents the type of mesh to create when placing cells between “domain partitions.” Two options are available: “uniform” and “symmetricgeometric.” For uniform, the cells are placed in the region with all cells having equal size. For symmetric-geometric, the cells are compressed toward the partitions so that there are more cells on either side of the mesh region. This can help focus computational intensity on the boundary areas where it is likely more desired. For symmetric-geometric mesh distribution, the mesh density parameter should be an even number to provide the symmetric condition.

#### **1.19.20.5 Field: X-Direction Geometric Coefficient**

This numeric field represents the compression of cell distribution if the x-direction mesh type is set to “symmetricgeometric.” If the mesh type is uniform, this field is not interpreted. For symmetric geometric, a value in this field equal to 1 would result in a uniform distribution, while a value of 2 would provide a highly skewed distribution.

#### **1.19.20.6 Field: Y-Direction Mesh Density Parameter**

See Field: X-Direction Mesh Density Parameter.

#### **1.19.20.7 Field: Y-Direction Mesh Type**

See Field: X-Direction Mesh Type.

#### **1.19.20.8 Field: Y-Direction Geometric Coefficient**

See Field: X-Direction Geometric Coefficient.

#### **1.19.20.9 Field: Z-Direction Mesh Density Parameter**

See Field: X-Direction Mesh Density Parameter.

#### **1.19.20.10 Field: Z-Direction Mesh Type**

See Field: X-Direction Mesh Type.

#### **1.19.20.11 Field: Z-Direction Geometric Coefficient**

See Field: X-Direction Geometric Coefficient.

#### **1.19.20.12 Field: Soil Thermal Conductivity**

The thermal conductivity of the soil, in W/m-K.

#### **1.19.20.13 Field: Soil Density**

The bulk density of the soil, in kg/m<sup>3</sup>.

#### **1.19.20.14 Field: Soil Specific Heat**

The specific heat of dry soil, in J/kg-K. If moisture is defined in this object, moisture and freezing effects are accounted for by varying the specific heat value.

**1.19.20.15 Field: Soil Moisture Content Volume Fraction**

A nominal value of soil moisture content to be used when evaluating soil thermal properties.

**1.19.20.16 Field: Soil Moisture Content Volume Fraction at Saturation**

A nominal value of soil moisture content when the soil is saturated, this is used in evaluating thermal properties of freezing soil

**1.19.20.17 Field: Type of Undisturbed Ground Temperature Object**

The type of undisturbed ground temperature object used to determine ground temperature for the farfield boundary conditions.

**1.19.20.18 Field: Name of Undisturbed Ground Temperature Object**

The name of the undisturbed ground temperature object used to determine ground temperature for the farfield boundary conditions.

**1.19.20.19 Field: This Domain Includes Basement Surface Interaction**

A yes/no field stating whether zone surfaces should be coupled to this domain.

**1.19.20.20 Field: Width of Basement Floor in Ground Domain**

If this domain does include basement interaction, this represents the width of the domain cutaway to include the basement. In essence, this is the width of basement floor to include in the ground simulation. This width should *include* the basement wall thickness.

**1.19.20.21 Field: Width of Basement Floor in Ground Domain**

If this domain does include basement interaction, this represents the depth of the domain cutaway to include the basement. In essence, this is the burial depth of the basement to include in the ground simulation. This depth should include the basement floor thickness.

**1.19.20.22 Field: Shift Pipe X Coordinates By Basement Width**

If this domain does include basement interaction, this flag specifies whether the pipe segment X-values should then be shifted by the basement width. In essence, this specifies the reference point for pipe segment x-values: if NO then the reference is domain  $x=0$ , if YES then the reference is the basement width point.

**1.19.20.23 Field: Name of Basement Wall Boundary Condition Model**

The name of an OtherSideConditions model defined in the input file and referenced by the surfaces which should be included as "wall surfaces" for the basement interaction part of the ground heat transfer model.

**1.19.20.24 Field: Name of Basement Wall Boundary Condition Model**

The name of an OtherSideConditions model defined in the input file and referenced by the surfaces which should be included as "floor surfaces" for the basement interaction part of the ground heat transfer model.

**1.19.20.25 Field: Convergence Criterion for the Outer Cartesian Domain Iteration Loop**

The maximum temperature deviation within any cell between one iteration and another to decide that the Cartesian domain has converged to within tolerance. A smaller value will improve accuracy and computation time. A smaller value should be accompanied by a higher number of iterations if maximum accuracy is desired.

**1.19.20.26 Field: Maximum Iterations in the Outer Cartesian Domain Iteration Loop**

The maximum number of iterations to make when performing temperature updates of the Cartesian coordinate system. The actual number of iterations made will of course depend on transient conditions and convergence tolerance.

**1.19.20.27 Field: Evapotranspiration Ground Cover Parameter**

Numeric field specifies the ground cover effects used in the evapotranspiration model at the ground surface heat balance. The values range from 0 (solid, nonpermeable ground surface) to 1.5 (wild growth).

**1.19.20.28 Field: Number of Pipe Circuits Entered for this Domain**

The number of pipe circuit objects which will be defined in the following fields.

#### **1.19.20.29 Field: Pipe Circuit 1 {... to N; extensible}**

A PipingSystem:Underground:PipeCircuit to be included in this domain. This indicates that the pipe circuit and all of the underlying pipe segments will be included during mesh development and heat transfer calculations within this domain. Any number of pipe circuits can be added, assuming all underlying pipe segments do not cause any conflicts for the mesh development engine (overlapping pipes, etc.).

#### **1.19.21 PipingSystem:Underground:PipeCircuit**

This section documents the pipe circuit object, which is used to specify information for the plant loop topology, such as inlet and outlet connections. This object also groups together pipe segments to define flow paths within a given pipe circuit.

##### **1.19.21.1 Field: Name**

This alpha field is used as an identifying field for the pipe circuit.

##### **1.19.21.2 Field: Pipe Thermal Conductivity**

The thermal conductivity of the pipe, in W/m-K.

##### **1.19.21.3 Field: Pipe Density**

The bulk density of the pipe, in kg/m<sup>3</sup>.

##### **1.19.21.4 Field: Pipe Specific Heat**

The specific heat of the pipe, in J/kg-K.

##### **1.19.21.5 Field: Pipe Inner Diameter**

The inner diameter of the pipe, in m.

##### **1.19.21.6 Field: Pipe Outer Diameter**

The outer diameter of the pipe, in m.

##### **1.19.21.7 Field: Design Flow Rate**

The "design" flow in this pipe circuit, in m<sup>3</sup>/s. This is the flow which this component will request during the simulation. Of course, other components and overall plant management will decide the flow actually given to this component.

##### **1.19.21.8 Field: Circuit Inlet Node Name**

The inlet node name for this circuit, which is used when placing this circuit on a branch on a plant or condenser loop.

##### **1.19.21.9 Field: Circuit Outlet Node Name**

The outlet node name for this circuit, which is used when placing this circuit on a branch on a plant or condenser loop.

##### **1.19.21.10 Field: Convergence Criterion for the Inner Radial Iteration Loop**

The maximum temperature deviation within any cell between one iteration and another to decide that the radial domain has converged to within tolerance. A smaller value will improve accuracy and computation time. A smaller value should be accompanied by a higher number of iterations if maximum accuracy is desired.

##### **1.19.21.11 Field: Maximum Iterations in the Inner Radial Iteration Loop**

The maximum number of iterations to make when performing temperature updates of the radial coordinate system. The actual number of iterations made will of course depend on transient conditions and convergence tolerance.

##### **1.19.21.12 Field: Number of Soil Nodes in the Inner Radial Near Pipe Mesh Region**

The number of soil nodes to discretize pipe cells. More information on mesh development is provided in the engineering reference manual.

##### **1.19.21.13 Field: Radial Thickness of Inner Radial Near Pipe Mesh Region**

The radial distance used to discretize pipe cells. More information on mesh development is provided in the engineering reference manual.

##### **1.19.21.14 Field: Number of Pipe Segments Entered for this Pipe Circuit**

The number of pipe segment objects which will be defined in the following fields.

#### 1.19.21.15 Field: Pipe Segment 1 {... to N; extensible}

A PipingSystem:Underground:PipeSegment to be included in this pipe circuit. The circuit is set up so that flow passes through theV segments in the order they are entered here.

#### 1.19.22 PipingSystem:Underground:PipeSegment

This section documents the pipe segment object, which is used to specify information for a single pipe segment placed at some x, y coordinate in the ground. The flow direction is also defined in this object to allow for careful description of varying flow paths. This can be useful for accounting for short circuiting effects if two pipes are placed in counterflow vs. parallel flow.

##### 1.19.22.1 Field: Name

This alpha field is used as an identifying field for the pipe segment.

##### 1.19.22.2 Field: X Position

This numeric field represents the x-direction placement of the pipe. If no basement is included in the simulation, this is measured from x=0. If a basement is included, and the domain object specifies that pipes should be shifted, this is measured from the basement wall.

##### 1.19.22.3 Field: Y Position

This numeric field represents the burial depth of the pipe, measured from the ground surface. This will always be a positive number.

##### 1.19.22.4 Field: Flow Direction

This alpha field is used to define the flow direction within this pipe segment. The choices are "increasing" or "decreasing." These can be chosen carefully to encapsulate specific short-circuiting effects due to varying flow configurations (circuiting).

An example of this object in an IDF is offered here for a foundation heat exchanger

### 1.19.23 PipingSystem:Underground Outputs

- HVAC, Average, Pipe Circuit Mass Flow Rate [kg/s]
- HVAC, Average, Pipe Circuit Inlet Temperature [C]
- HVAC, Average, Pipe Circuit Outlet Temperature [C]
- HVAC, Average, Pipe Segment Inlet Temperature [C]
- HVAC, Average, Pipe Segment Outlet Temperature [C]
- HVAC, Average, Pipe Circuit Fluid Heat Transfer Rate [W]
- HVAC, Average, Pipe Segment Fluid Heat Transfer Rate [W]

#### 1.19.23.1 Pipe Circuit Mass Flow Rate [kg/s]

The output provides the mass flow rate currently being sent through the pipe circuit.

#### 1.19.23.2 Pipe Circuit Inlet Temperature [C]

#### 1.19.23.3 Pipe Circuit Outlet Temperature [C]

Temperature of fluid at the inlet and outlet of a given pipe circuit.

#### 1.19.23.4 Pipe Segment Inlet Temperature [C]

### 1.19.23.5 Pipe Segment Outlet Temperature [C]

Temperature of fluid at the inlet and outlet of a given pipe segment.

### 1.19.23.6 Pipe Circuit Fluid Heat Transfer Rate [W]

This is the fluid heat gain or loss in the pipe circuit, in Watts.

### 1.19.23.7 Pipe Segment Fluid Heat Transfer Rate [W]

This is the fluid heat gain or loss in the pipe segment, in Watts.

## 1.19.24 Duct

The Duct object is a component for air systems that is a direct analogue for Pipe:Adiabatic in the fluid loops. It is used when it is necessary (due to the HVAC system configuration) to have a branch that has no functional components. This case most often arises for a bypass branch. Since every branch must have at least one component, the Duct component is used for this situation. The duct is an adiabatic, pass-through component; all of its inlet conditions are passed through unchanged to its outlet.

### 1.19.24.1 Field: Name

This is the unique name for this component. Any reference to this component (in a BranchList, for instance) will refer to it by this name.

### 1.19.24.2 Field: Inlet Node Name

The name of the component's air inlet node.

### 1.19.24.3 Field: Outlet Node Name

The name of the component's air outlet node.

Below is an example input for Duct.

```
DUCT,  
  VAV Sys 1 Bypass Duct,           !- Name  
  VAV Sys 1 Bypass Duct Inlet Node, !- Inlet Node Name  
  VAV Sys 1 Bypass Duct Outlet Node;!- Outlet Node Name
```

## 1.19.25 Duct Outputs

There are no outputs for Duct.

## 1.20 Group – Plant-Condenser Loops

### 1.20.1 PlantLoop

The main elements of the PlantLoop syntax are described in further detail below. A map of how the input for this portion of the HVAC input fits together is provided in the following diagram.

!|PlantLoopSyntax (media/image135.png)

Figure 73. Plant Loop Input Syntax Map

#### 1.20.1.1 Field: Name

This alpha field is used as an identifying field for the plant loop.

#### 1.20.1.2 Field: Fluid Type

This alpha field must be a keyword selected from the list of available fluids for an EnergyPlus plant loop. Either **Water**, **Steam** or **UserDefinedFluidType** may be used. If the UserDefinedFluidType keyword is used, the following input field i.e. User Defined Fluid Type must have a value (namely the name of a FluidProperties:GlycolConcentration object).

#### 1.20.1.3 Field: User Defined Fluid Type

This alpha field must be specified when the previous field is set to **UserDefinedFluidType** otherwise it could be left blank. **Water**, **EthyleneGlycol**, **PropyleneGlycol** and **Steam** are all “built-in” fluids for EnergyPlus (that is, all of the appropriate properties are contained within the program). If the fluid specified here is a mixture of water and ethylene or propylene glycol, then only FluidProperties:GlycolConcentration objects need to be specified and the name of the appropriate one is used here. For another water/glycol mixture, a complete set of fluid property data (FluidProperties:Name and FluidProperties:Temperature

objects plus multiple FluidProperties:Concentration objects for specific heat, density, etc.) must be specified (Ref dataset: GlycolPropertiesRefData.idf).

#### **1.20.1.4 Field: Plant Equipment Operation Scheme Name**

This alpha field is used as an identifying field for the plant operation scheme. This field ties to the PlantEquipmentOperationSchemes input structure, which must also be defined.

#### **1.20.1.5 Field: Loop Temperature Setpoint Node Name**

This alpha field is used to identify the node which the Loop Manager will access the temperature setpoint that it will try to maintain. This is typically the Plant Loop Supply Side Outlet Node so that it will not interfere with component temperature setpoints. An associated temperature setpoint manager will need to be defined.

#### **1.20.1.6 Field: Maximum Loop Temperature**

This numeric field contains the maximum allowable temperature in Celsius for this loop.

#### **1.20.1.7 Field: Minimum Loop Temperature**

This numeric field contains the minimum allowable temperature in Celsius for this loop.

#### **1.20.1.8 Field: Maximum Loop Flow Rate**

This numeric field contains the maximum loop flow rate in cubic meters per second. This parameter is also used when the user chooses to autocalculate the loop volume. See Volume of the Plant Loop below and the Engineering Manual for more details. This field is autosizable.

#### **1.20.1.9 Field: Minimum Loop Flow Rate**

This numeric field contains the minimum loop flow rate in cubic meters per second.

#### **1.20.1.10 Field: Plant Loop Volume**

Volume of the plant loop in m<sup>3</sup>. This numeric field contains the loop volume for the entire loop, i.e. both the demand side and the supply side. This is used for the loop capacitance calculation.. Loop volume (m<sup>3</sup>) could be calculated from pipe size data but this is not usually known. If zero volume is specified the loop has no fluid heat capacity. If a very large capacitance is specified unrealistic time delay may result and there may be poor response to changes in loop setpoint temperature. The loop capacitance **autocalculate** option gives reasonable values for most system sizes. This calculation is described in the Engineering Reference manual.

#### **1.20.1.11 Field: Plant Side Inlet Node Name**

This required alpha field contains the identifying name given to the Plant Side Inlet Node. This node is the inlet to the supply side of the loop.

#### **1.20.1.12 Field: Plant Side Outlet Node Name**

This required alpha field contains the identifying name given to the Plant Side Outlet Node. This node is the outlet of the supply side of the loop.

#### **1.20.1.13 Field: Plant Side Branch List Name**

This required alpha field contains the identifying name given to the Plant Side Branch List. The list referenced here should list all the branches on the supply side of the loop.

#### **1.20.1.14 Field: Plant Side Connector List Name**

This alpha field contains the identifying name given to the Plant Side Connector List. The list referenced here should list the splitter and mixer on the supply side of the loop.

#### **1.20.1.15 Field: Demand Side Inlet Node Name**

This required alpha field contains the identifying name given to the Demand Side Inlet Node. This node is the inlet to the demand side of the loop.

#### **1.20.1.16 Field: Demand Side Outlet Node Name**

This required alpha field contains the identifying name given to the Demand Side Outlet Node. This node is the outlet of the demand side of the loop.

#### **1.20.1.17 Field: Demand Side Branch List Name**

This required alpha field contains the identifying name given to the Demand Side Branch List. The list referenced here should list all the branches on the demand

side of the loop.

#### 1.20.1.18 Field: Demand Side Connector List Name

This alpha field contains the identifying name given to the Demand Side Connector List. The list referenced here should list the splitter and mixer on the demand side of the loop.

#### 1.20.1.19 Field: Load Distribution Scheme

This alpha field contains the Load Distribution Scheme Keyword. The Load Distribution Scheme selects the algorithm used to sequence equipment operation in order to meet the plant loop demand. Currently, five schemes are functional. **Optimal** operates each piece of equipment at its optimal part load ratio and will operate the last component between its minimum and maximum part load ratio in order to meet the loop demand. **SequentialLoad** loads each piece of equipment sequentially in the order specified in the PlantEquipmentList to its maximum part load ratio and will operate the last required piece of equipment between its minimum and maximum part load ratio in order to meet the loop demand. **UniformLoad** evenly distributes the loop demand among all available components on the equipment list for a given load range. **SequentialUniformPLR** loads all equipment on the PlantEquipmentList to a uniform part load ratio (PLR). Components are loaded sequentially based on the order specified in the PlantEquipmentList until each component is fully loaded, at which point the next subsequent component is added and the load is distributed uniformly based on PLR between the components. **UniformPLR** will load all equipment on the PlantEquipmentList to a uniform part load ratio (PLR). No equipment will be loaded below its minimum PLR. If the total load is less than the sum of all equipment on the PlantEquipmentList operating at their respective minimum PLRs, then the last item in the equipment list is dropped and the load is distributed based on a uniform PLR for the remaining plant equipment.

Note: For all schemes, if the load for any individual component is less than the component load at the minimum PLR, the individual component model will false load or reduce duty cycle while operating at the minimum part load ratio until the load is met.

#### 1.20.1.20 Field: Availability Manager List Name

This alpha field contains the identifying name given to the System Availability Manager List.

#### 1.20.1.21 Field: Plant Loop Demand Calculation Scheme

There are two plant loop demand calculations schemes in EnergyPlus. There is a SingleSetpoint and a DualSetpointDeadband; the SingleSetpoint is the default if this field is left blank. In the SingleSetpoint scheme the Plant Loop requires that a Setpoint Manager set a single setpoint value (on Node%TempSetpoint). Examples of this setpoint manager would be: SetpointManager:Scheduled, SetpointManager:OutsideAir, etc. For the DualSetpointDeadband scheme the Plant Loop requires that a Setpoint Manager set the high and low setpoint values (for Node%TempSetpointHi and Node%TempSetpointLo). Examples of this Setpoint manager would be: SetpointManager:Scheduled:DualSetpoint.

The plant loop demand calculation scheme determines the amount of heating or cooling necessary to bring the temperature of the Plant Loop to its setpoint(s). When this value is determined then the load distribution scheme explained in the previous section takes this value and distributes the load to the appropriate equipment. The demand calculation scheme determines how the load is calculated. See more information in the Engineering Document.

#### 1.20.1.22 Field: Common Pipe Simulation

This field specifies a primary-secondary plant loop simulation. When a common pipe option is specified, the plant side of the loop is the primary loop and the demand side of the loop is the secondary loop, and a pump object must be placed on the demand side inlet branch. The three options are “None”, “CommonPipe” and “TwoWayCommonPipe”. “None” means that there is no secondary loop and the plant loop is modeled as a single primary loop. “CommonPipe” means that the common pipe interface does not attempt any temperature control, it only satisfies secondary (demand side) flow requests. “TwoWayCommonPipe” allows control of the secondary (demand side) inlet temperature or the primary (plant side) inlet temperature by placing a setpoint on the corresponding node. If this field is left blank, it will default to “None”. If the field is set to “None” and the program finds a pump on the demand side it will result in a fatal error. If the field is set to “CommonPipe” or “TwoWayCommonPipe” and the program does not find a pump on the demand side it will result in a fatal error. The common pipe simulation is currently limited to simulating loop pumps, i.e. each pump should be placed on the inlet branch of the plant side or demand side of the loop.

#### 1.20.1.23 Field: Pressure Simulation Type

This field lets user to choose if this plant loop will be involved in a pressure drop calculation. This requires that at least one branch on the loop have pressure drop data. If not, an error will be thrown due to the input mismatch. Currently there are two pressure drop simulation types: “PumpPowerCorrection” and “LoopFlowCorrection”. In both of these methods, branch pressure drop data is used to calculate a dynamic loop pressure drop and is used to update pumping power accordingly. The flow correction method allows the user to enter information regarding the pressure curve of a constant speed pump so that the simulation can dynamically resolve the pressure vs. flow relationship in the plant loop. This is limited to constant speed pumps, as the variable speed pumps are expected to resolve as if it were controlled by a variable drive, so that they can inherently meet any pressure and flow demand required by the loop. This is also limited to “loop pumps”, where there is a single pump on the plant loop. Common pipe simulations and “branch pump” simulations are not compatible with this level of pressure simulation. See the documentation for the Pump:ConstantSpeed in order to determine required inputs for this pressure simulation method to be performed. In the pressure drop system, parallel flow rates are not resolved (to match the pressure drop for the parallel system). Enhancements to this calculation are planned which will allow parallel branch flow resolution. See the Engineering Reference document for more information on how this works.

An example of this statement used in an IDF is:

```

```

In the above example input there is no system availability manager specified and the Demand Calculation Scheme will default to SingleSetpoint using a single setpoint manager. Common pipe simulation field in the above example will default to "NONE" since it is not specified.

## 1.20.2 Plant Loop Outputs

In the following output variables, "Debug" denotes variables that are used primarily by the developers and whose names and application may be cryptic to users.

- HVAC,Average,Plant Supply Side Cooling Demand Rate [W]
- HVAC,Average,Plant Supply Side Heating Demand Rate [W]
- HVAC,Average,Plant Supply Side Inlet Mass Flow Rate [kg/s]
- HVAC,Average,Plant Supply Side Inlet Temperature [C]
- HVAC,Average,Plant Supply Side Outlet Temperature [C]
- HVAC,Average,Plant Supply Side Not Distributed Demand Rate [W]
- HVAC,Average,Plant Supply Side Unmet Demand Rate [W]
- HVAC,Sum,Plant Solver Sub Iteration Count []
- HVAC,Sum,Plant Solver Half Loop Calls Count []
- HVAC,Average,Debug Plant Loop Bypass Fraction
- HVAC,Average,Debug Plant Last Simulated Loop Side [-]
- HVAC,Average,Plant Common Pipe Mass Flow Rate [Kg/s]
- HVAC,Average,Plant Common Pipe Temperature [C]
- HVAC,Average,Plant Common Pipe Flow Direction Status []
- HVAC,Average,Plant Common Pipe Primary Mass Flow Rate [Kg/s]
- HVAC,Average,Plant Common Pipe Secondary Mass Flow Rate [Kg/s]
- HVAC,Average,Primary Side Common Pipe Flow Direction []
- HVAC,Average,Secondary Side Common Pipe Flow Direction []
- HVAC,Average,Plant Common Pipe Primary to Secondary Mass Flow Rate [Kg/s]
- HVAC,Average,Plant Common Pipe Secondary to Primary Mass Flow Rate [Kg/s]
- HVAC,Average,Plant System Cycle On Off Status []
- HVAC,Average,Plant Demand Side Loop Pressure Difference [Pa]
- HVAC,Average,Plant Supply Side Loop Pressure Difference [Pa]
- HVAC,Average,Plant Loop Pressure Difference [Pa]

#### 1.20.2.1 Plant Supply Side Cooling Demand Rate [W]

This is the value of the net demand required to meet the cooling setpoint of the loop. If the loop setpoint is met for the current HVAC timestep, Plant Supply Side Cooling Demand Rate will equal sum of the total cooling demand from the demand side coils on the loop. It will also equal the cooling output of all chillers (or other cooling equipment) on the loop less any pump heat added to the fluid. For example, for a chilled water loop with one chiller and one pump serving one chilled water coil: Plant Supply Side Cooling Demand Rate will equal the chiller evaporator heat transfer less the pump heat to fluid, and it will also equal the chilled water coil total cooling output.

If the plant loop setpoint is not met, Plant Supply Side Cooling Demand Rate will equal the sum of the total cooling demand from the demand side coils on the loop plus the additional cooling required to bring the loop flow to setpoint. If the loop remains off setpoint for successive timesteps, the demand required to return to setpoint will repeat in each timestep until the loop reaches setpoint. For this reason, Plant Supply Side Cooling Demand Rate should not be summed over time, because it will overstate the demand whenever the loop is off setpoint.

#### 1.20.2.2 Plant Supply Side Heating Demand Rate [W]

This is the value of the net demand required to meet the heating setpoint of the loop. If the loop setpoint is met for the current HVAC timestep, Plant Supply Side Heating Demand Rate will equal sum of the total heating demand from the demand side coils on the loop. It will also equal the heating output of all boilers (or other heating equipment) on the loop plus any pump heat added to the fluid. For example, for a hot water loop with one boiler and one pump serving one hot water coil: Plant Supply Side Heating Demand Rate will equal the boiler heat transfer plus the pump heat to fluid, and it will also equal the hot water coil total heating output.

If the plant loop setpoint is not met, Plant Supply Side Heating Demand Rate will equal the sum of the total heating demand from the demand side coils on the loop plus the additional heating required to bring the loop flow to setpoint. If the loop remains off setpoint for successive timesteps, the demand required to return to setpoint will repeat in each timestep until the loop reaches setpoint. For this reason, Plant Supply Side Heating Demand Rate should not be summed over time, because it will overstate the demand whenever the loop is off setpoint.

#### 1.20.2.3 Plant Supply Side Inlet Mass Flow Rate [kg/s]

This is the value of the mass flow rate at the Inlet to Plant Loop on the supply side. There is not an associated Plant Loop outlet node flow rate since continuity must be maintained in the loop and the outlet must be the same.

#### 1.20.2.4 Plant Supply Side Inlet Temperature [C]

This is the value of the temperature at the Inlet to the plant loop on the supply side.

#### 1.20.2.5 Plant Supply Side Outlet Temperature [C]

This is the value of the temperature at the outlet to the plant loop on the supply side.

#### 1.20.2.6 Plant Supply Side Not Distributed Demand Rate [W]

This is the value of the demand that could not be distributed to the plant equipment because of some constraint in the plant operation scheme. This is a record of the loop operation scheme supervisory controls after attempting to distribute the load. For example it would be non-zero in situations where the load is larger than the upper limit of capacities set for the plant equipment controls. This output is for *before* the equipment has actually been simulated whereas the separate output Plant Supply Side Unmet Demand Rate is for *after* the equipment has simulated.

#### 1.20.2.7 Plant Supply Side Unmet Demand Rate [W]

This is the value of the demand NOT provided by the plant equipment to meet the heating or cooling setpoint of the loop. The value is positive when the plant equipment cannot meet the setpoint, and the value is negative when the plant equipment provides more than enough heating or cooling to meet the setpoint. A negative value can happen when the amount of demand is smaller than the minimum capacity of the equipment using the minimum part load ratio.

#### 1.20.2.8 Plant Solver Sub Iteration Count [ ]

This is the count of iterations that the overall plant simulation used over the period of time being reported. This high-level output is from the plant solver used for all the plant loops and condenser loops in the model.

#### 1.20.2.9 Plant Solver Half Loop Calls Count

This is the count of calls to model individual half-loops that occurred during the overall plant simulation over the period of time being reported. This includes all the half-loops for both plant loops and condenser loops.

#### 1.20.2.10 Plant Common Pipe Mass Flow Rate [Kg/s]

This output gives the magnitude of the flow through common pipe. The value is averaged over the reporting interval.

#### 1.20.2.11 Plant Common Pipe Temperature [C]

This output gives the value of the temperature of the fluid flowing through common pipe. This value is averaged over the reporting interval.

#### **1.20.2.12 Plant Common Pipe Flow Direction Status []**

This output gives the direction of flow in common pipe. The value is an integer and can be 0, 1 or 2. Since the output value is averaged over reporting interval, a non-integer value may be shown as an output when the reporting interval is not detailed. An output value of 0 means that there was no flow in common pipe. An output value of 1 means that the secondary flow is greater than primary flow, whereas a value of 2 means that primary flow is greater than secondary flow.

#### **1.20.2.13 Plant Common Pipe Primary Mass Flow Rate [Kg/s]**

This output variable gives the mass flow in the primary side common pipe leg in a Two-Way common pipe simulation. Value is averaged over the reporting interval.

#### **1.20.2.14 Plant Common Pipe Secondary Mass Flow Rate [Kg/s]**

This output variable gives the mass flow in the secondary side common pipe leg in a Two-Way common pipe simulation. Value is averaged over the reporting interval.

#### **1.20.2.15 Primary Side Common Pipe Flow Direction []**

This output variable gives the direction of flow in a primary side common pipe leg in a Two-Way Common Pipe Simulation. A value of zero means there was no flow in the pipe. A value of 1 means the flow was from top to bottom in EnergyPlus loop schematic. So for primary side, a value of 1 means the flow is from Primary side inlet to Primary side outlet and a value of 2 means flow is from Primary side outlet to Primary side inlet.

#### **1.20.2.16 Secondary Side Common Pipe Flow Direction []**

This output variable gives the direction of flow in a Secondary side common pipe leg in a Two-Way Common Pipe Simulation. A value of zero means there was no flow in the pipe. A value of 1 means the flow was from top to bottom in EnergyPlus loop schematic. So for Secondary side, a value of 1 means the flow is from Secondary side outlet to Secondary side inlet and a value of 2 means flow is from Secondary side inlet to Secondary side outlet. Note that this is opposite to the primary side common pipe.

#### **1.20.2.17 Plant Common Pipe Primary to Secondary Mass Flow Rate [Kg/s]**

This output variable gives the mass flow from primary to secondary side in a Two-Way common pipe simulation. Value is averaged over the reporting interval.

#### **1.20.2.18 Plant Common Pipe Secondary to Primary Mass Flow Rate [Kg/s]**

This output variable gives the mass flow from secondary to primary side in a Two-Way common pipe simulation. Value is averaged over the reporting interval.

#### **1.20.2.19 Plant System Cycle On Off Status**

This field is the availability status of a Plant Loop. This status flag is a result of the calculations made by the System Availability Manager(s) listed in a System Availability Manager List. When a single availability manager is used in a System Availability Manager List, this is also the availability status reported by the specific availability manager (Ref. System Availability Manager Outputs). When multiple availability managers are used in a System Availability Manager List, the loop availability status is determined by the rules associated with Plant Loops (see rules described for Group – System Availability Managers). The control status outputs are represented using integers 0 through 2.. These integers represent *NoAction* (0), *ForceOff* (1), and *CycleOn* (2). Since the status output is averaged, the output result may not correspond to the values described here when output variable frequencies other than detailed are used. Use the “detailed” reporting frequency (Ref. Output:Variable object) to view the availability status at each simulation timestep.

#### **1.20.2.20 Plant Demand Side Loop Pressure Difference [Pa]**

This field allows the user to output the demand side pressure drop of a plant loop. This output is only recognized if a valid pressure simulation is being performed. To do this, the user must specify a pressure simulation type as an input in the PlantLoop object, and input at least one pressure drop curve on a branch of the plant loop. This particular output is only relevant if the user puts that curve on the demand side of the loop.

#### **1.20.2.21 Plant Supply Side Loop Pressure Difference [Pa]**

This field allows the user to output the supply side pressure drop of a plant loop. This output is only recognized if a valid pressure simulation is being performed. To do this, the user must specify a pressure simulation type as an input in the PlantLoop object, and input at least one pressure drop curve on a branch of the plant loop. This particular output is only relevant if the user puts that curve on the supply side of the loop.

#### **1.20.2.22 Plant Loop Pressure Difference [Pa]**

This output is the total pressure drop of a plant loop. This output is only recognized if a valid pressure simulation is being performed. To do this, the user must specify a pressure simulation type as an input in the PlantLoop object, and input at least one pressure drop curve on a branch of the plant loop. This particular output is relevant regardless of the location of pressure drop curves: demand side, supply side, or both.

The following advanced output variables are also available for plant loops (and condenser loops) when advanced output variables are requested (e.g. "Output:Diagnostics, DisplayAdvancedReportVariable;").

- HVAC,Average,Plant Demand Side Lumped Capacitance Temperature [C]
- HVAC,Average,Plant Supply Side Lumped Capacitance Temperature [C]
- HVAC,Average,Plant Component Distributed Demand Rate [W]

#### 1.20.2.23 Plant Demand Side Lumped Capacitance Temperature [C]

#### 1.20.2.24 Plant Supply Side Lumped Capacitance Temperature [C]

These two outputs are the temperature of the plant (or condenser) loop's working fluid where the two half-loops interface together. The program models heat capacitance in the volume of fluid inside the plant loop itself using two simple models for "well-stirred" tanks located at each of the half-loop inlet and outlet pairs. These tank models also receive the heat transferred to the fluid by the work done by pumping and resulting friction heating. One output is for the point where the fluid leaves the supply side and enters the demand side. The other output is for the point where the fluid leaves the demand side and enters the supply side.

#### 1.20.2.25 Plant Component Distributed Demand Rate [W]

This output is available for every component on every branch in a plant (or condenser) loop and shows the outcome of the load dispatch performed by the operation schemes. This is the load in watts passed from the supervisor routines to the equipment component models. This provides a record of what a particular component was asked to do by the supervisory routines. This can be useful for diagnosing issues in operation schemes when a component or loop is failing to meet the load.

### 1.20.3 CondenserLoop

The condenser loop input is very similar to that for the plant loop. As of version 7, the two loops are modeled the same way and inside the program all condenser loops are just plant loops. (In future versions of the program, this CondenserLoop object might be deprecated and these loops will be described using the PlantLoop object.) The main differences are the applicable components and operation schemes. This is depicted in the following diagram.

!{CondenserLoopSyntax (media/image136.png)

Figure 74. Condenser Loop Input Syntax Map

#### 1.20.3.1 Field: Name

This alpha field is used as an identifying field for the condenser loop.

#### 1.20.3.2 Field: Fluid Type

This alpha field must be a keyword selected from the list of available fluids for an EnergyPlus plant loop. Either **Water** or **UserDefinedFluidType** may be used. If the **UserDefinedFluidType** keyword is used, the following input field i.e. User Defined Fluid Type must have a value (namely the name of a FluidProperties:GlycolConcentration object).

#### 1.20.3.3 Field: User Defined Fluid Type

This alpha field must be specified when the previous field is set to **UserDefinedFluidType** otherwise it could be left blank. **Water**, **EthyleneGlycol**, and **PropyleneGlycol** are all "built-in" fluids for EnergyPlus (that is, all of the appropriate properties are contained within the program). If the fluid specified here is a mixture of water and ethylene or propylene glycol, then only FluidProperties:GlycolConcentration objects need to be specified and the name of the appropriate one is used here. For another water/glycol mixture, a complete set of fluid property data (FluidProperties:Name and FluidProperties:Temperature objects plus multiple FluidProperties:Concentration objects for specific heat, density, etc.) must be specified (Ref dataset: GlycolPropertiesRefData.idf).

#### 1.20.3.4 Field: Condenser Equipment Operation Scheme Name

This alpha field is used as an identifying field for the condenser operation scheme. This field ties to the Condenser Operation Schemes input structure, which must also be defined.

#### 1.20.3.5 Field: Condenser Loop Temperature Setpoint Node Name

This alpha field is used to identify the node which the Loop Manager will access the temperature setpoint that it will try to maintain. This is typically the Condenser Loop Supply Side Outlet Node so that it will not interfere with component temperature setpoints. An associated temperature setpoint manager will need to be defined.

#### 1.20.3.6 Field: Maximum Loop Temperature

This numeric field contains the maximum allowable temperature in Celsius for this loop.

### 1.20.3.7 Field: Minimum Loop Temperature

This numeric field contains the minimum allowable temperature in Celsius for this loop. This minimum loop temperature is used by the cooling towers to make sure that the minimum is not violated to keep the equipment safe. The minimum is also used to trigger the minimum temperature warning and will notify the user if it gets too low.

### 1.20.3.8 Field: Maximum Loop Flow Rate

This numeric field contains the maximum loop flow rate in cubic meters per second. This field is autosizable.

### 1.20.3.9 Field: Minimum Loop Flow Rate

This numeric field contains the minimum loop flow rate in cubic meters per second.

### 1.20.3.10 Field: Condenser Loop Volume

Volume of the condenser loop in  $m^3$ . This numeric field contains the loop volume for the entire loop, i.e., both the demand side and the supply side. This is used for the loop capacitance calculation. Loop volume ( $m^3$ ) could be calculated from pipe size data but this is not usually known. If zero volume is specified the loop has no fluid heat capacity. If a very large capacitance is specified unrealistic time delay may result and there may be poor response to changes in loop setpoint temperature. The loop capacitance **autocalculate** option gives reasonable values for most system sizes. This calculation is described in the Engineering Reference manual.

### 1.20.3.11 Field: Condenser Side Inlet Node Name

This required alpha field contains the identifying name given to the Condenser Side Inlet Node. This node is the inlet to the supply side of the loop.

### 1.20.3.12 Field: Condenser Side Outlet Node Name

This required alpha field contains the identifying name given to the Condenser Side Outlet Node. This node is the outlet of the supply side of the loop.

### 1.20.3.13 Field: Condenser Side Branch List Name

This required alpha field contains the identifying name given to the Condenser Side Branch List. The list referenced here should list all the branches on the supply side of the loop.

### 1.20.3.14 Field: Condenser Side Connector List Name

This required alpha field contains the identifying name given to the Condenser Side Connector List. The list referenced here should list the splitter and mixer on the supply side of the loop.

### 1.20.3.15 Field: Demand Side Inlet Node Name

This required alpha field contains the identifying name given to the Demand Side Inlet Node. This node is the inlet to the demand side of the loop.

### 1.20.3.16 Field: Demand Side Outlet Nodes Name

This required alpha field contains the identifying name given to the Demand Side Outlet Node. This node is the outlet of the demand side of the loop.

### 1.20.3.17 Field: Condenser Demand Side Branch List Name

This required alpha field contains the identifying name given to the Demand Side Branch List. The list referenced here should list all the branches on the demand side of the loop.

### 1.20.3.18 Field: Condenser Demand Side Connector List Name

This required alpha field contains the identifying name given to the Demand Side Connector List. The list referenced here should list the splitter and mixer on the demand side of the loop.

### 1.20.3.19 Field: Load Distribution Scheme

This alpha field contains the Load Distribution Scheme Keyword. The Load Distribution Scheme selects the algorithm used to sequence equipment operation in order to meet the plant loop demand. Currently, five schemes are functional. **Optimal** operates each piece of equipment at its optimal part load ratio and will operate the last component between its minimum and maximum part load ratio in order to meet the loop demand. **SequentialLoad** loads each piece of equipment sequentially in the order specified in the PlantEquipmentList to its maximum part load ratio and will operate the last required piece of equipment between its minimum and maximum part load ratio in order to meet the loop demand. **UniformLoad** evenly distributes the loop demand among all available components on the equipment list for a given load range. **SequentialUniformPLR** loads all equipment on the PlantEquipmentList to a uniform part load ratio (PLR). Components are loaded sequentially based on the order specified in the PlantEquipmentList until each component is fully loaded, at which point the next

subsequent component is added and the load is distributed uniformly based on PLR between the components. **UniformPLR** will load all equipment on the PlantEquipmentList to a uniform part load ratio (PLR). No equipment will be loaded below its minimum PLR. If the total load is less than the sum of all equipment on the PlantEquipmentList operating at their respective minimum PLRs, then the last item in the equipment list is dropped and the load is distributed based on a uniform PLR for the remaining plant equipment.

Note: For all schemes, if the load for any individual component is less than the component load at the minimum PLR, the individual component model will false load or reduce duty cycle while operating at the minimum part load ratio until the load is met.

### 1.20.3.20 Field: Pressure Simulation Type

This field lets user to choose if this plant loop will be involved in a pressure drop calculation. This requires that at least one branch on the loop have pressure drop data. If not, an error will be thrown due to the input mismatch. Currently there are two pressure drop simulation types: "PumpPowerCorrection" and "LoopFlowCorrection". In both of these methods, branch pressure drop data is used to calculate a dynamic loop pressure drop and is used to update pumping power accordingly. The flow correction method allows the user to enter information regarding the pressure curve of a constant speed pump so that the simulation can dynamically resolve the pressure vs. flow relationship in the plant loop. This is limited to constant speed pumps, as the variable speed pumps are expected to resolve as if it were controlled by a variable drive, so that they can inherently meet any pressure and flow demand required by the loop. This is also limited to "loop pumps", where there is a single pump on the plant loop. Common pipe simulations and "branch pump" simulations are not compatible with this level of pressure simulation. See the documentation for the Pump:ConstantSpeed in order to determine required inputs for this pressure simulation method to be performed. In the pressure drop system, parallel flow rates are not resolved (to match the pressure drop for the parallel system). Enhancements to this calculation are planned which will allow parallel branch flow resolution. See the Engineering Reference document for more information on how this works.

An example of this statement used in an IDF is:

### 1.20.4 Condenser Loop Outputs

- HVAC,Average,Plant Supply Side Cooling Demand Rate [W]
- HVAC,Average,Plant Supply Side Heating Demand Rate [W]
- HVAC,Average,Plant Supply Side Inlet Mass Flow Rate [kg/s]
- HVAC,Average,Plant Supply Side Inlet Temperature [C]
- HVAC,Average,Plant Supply Side Outlet Temperature [C]
- HVAC,Average,Cond Loop Demand Not Distributed [W]
- HVAC,Average,Plant Supply Side Unmet Demand Rate [W]
- HVAC,Average,Plant Demand Side Loop Pressure Difference [Pa]
- HVAC,Average,Plant Supply Side Loop Pressure Difference [Pa]
- HVAC,Average,Plant Loop Pressure Difference [Pa]

#### 1.20.4.1 Plant Supply Side Cooling Demand Rate [W]

This is the value of the net demand required to meet the cooling setpoint of the loop. If the loop setpoint is met for the current HVAC timestep, Plant Supply Side Cooling Demand Rate will equal sum of the total cooling demand from the demand side components on the loop (typically condenser coils of chillers, etc.). It will also equal the cooling output of all condensing equipment such as cooling towers on the loop less any pump heat added to the fluid. For example, for a condenser loop with one tower and one pump serving one chiller, Plant Supply Side Cooling Demand Rate will equal the tower water-side heat transfer less the pump heat to fluid, and it will also equal the chiller condenser heat transfer rate.

If the condenser loop setpoint is not met, Plant Supply Side Cooling Demand Rate will equal the sum of the total cooling demand from the demand side components on the loop plus the additional cooling required to bring the loop flow to setpoint. If the loop remains off setpoint for successive timesteps, the demand required to return to setpoint will repeat in each timestep until the loop reaches setpoint. For this reason, Plant Supply Side Cooling Demand Rate should not be summed over time, because it will overstate the demand whenever the loop is off setpoint.

#### 1.20.4.2 Plant Supply Side Heating Demand Rate [W]

This is the value of the net demand required to meet the heating setpoint of the loop. If the loop setpoint is met for the current HVAC timestep, Plant Supply Side Heating Demand Rate will equal sum of the total heating demand from the demand side components on the loop. It will also equal the heating output of all heating equipment on the supply side of the loop plus any pump heat added to the fluid. For example, for a condenser loop with one ground loop heat exchanger and one pump serving one water-to-water heat pump, Plant Supply Side Heating Demand Rate will equal the ground loop heat transfer plus the pump heat to fluid, and it will also equal the heat pump condenser side heat transfer rate.

If the condenser loop setpoint is not met, Plant Supply Side Heating Demand Rate will equal the sum of the total heating demand from the demand side components on the loop plus the additional heating required to bring the loop flow to setpoint. If the loop remains off setpoint for successive timesteps, the demand required to return to setpoint will repeat in each timestep until the loop reaches setpoint. For this reason, Plant Supply Side Heating Demand Rate should not be summed over time, because it will overstate the demand whenever the loop is off setpoint.

#### 1.20.4.3 Plant Supply Side Inlet Mass Flow Rate [kg/s]

This is the value of the mass flow rate at the Inlet to Condenser Loop on the supply side. There is not an associated Condenser Loop outlet node flow rate since continuity must be maintained in the loop and the outlet must be the same.

#### 1.20.4.4 Plant Supply Side Inlet Temperature [C]

This is the value of the temperature at the Inlet to the condenser loop on the supply side.

#### 1.20.4.5 Cond Loop OutletNode Temperature [C]

This is the value of the temperature at the outlet to the condenser loop on the supply side.

#### 1.20.4.6 Cond Loop Demand Not Distributed [W]

This is the value of the demand that could not be distributed to the condenser equipment because of some constraint in the operation scheme. This is a record of the loop operation scheme supervisory controls after attempting to distribute the load. For example it would be non-zero in situations where the load is larger than the upper limit of capacities set for the condenser equipment controls. This output is for *before* the equipment has actually been simulated whereas the separate output Plant Supply Side Unmet Demand Rate is for *after* the equipment has simulated.

#### 1.20.4.7 Plant Supply Side Unmet Demand Rate [W]

This is the value of the demand NOT provided by the condenser equipment to meet the heating or cooling setpoint of the loop. The value is positive when the

condenser equipment cannot meet the setpoint, and the value is negative when the condenser equipment provides more than enough heating or cooling to meet the setpoint. A negative value can happen when the amount of demand is smaller than the minimum capacity of the equipment using the minimum part load ratio.

#### **1.20.4.8 Plant Demand Side Loop Pressure Difference [Pa]**

This field is the demand side pressure drop of a condenser loop. This output is only recognized if a valid pressure simulation is being performed. To do this, the user must specify a pressure simulation type as an input in the CondenserLoop object, and input at least one pressure drop curve on a branch of the plant/condenser loop. This particular output is only relevant if the user puts that curve on the demand side of the loop.

#### **1.20.4.9 Plant Supply Side Loop Pressure Difference [Pa]**

This field is the supply side pressure drop of a condenser loop. This output is only recognized if a valid pressure simulation is being performed. To do this, the user must specify a pressure simulation type as an input in the CondenserLoop object, and input at least one pressure drop curve on a branch of the plant/condenser loop. This particular output is only relevant if the user puts that curve on the supply side of the loop.

#### **1.20.4.10 Plant Loop Pressure Difference [Pa]**

This field is the total pressure drop of a condenser loop. This output is only recognized if a valid pressure simulation is being performed. To do this, the user must specify a pressure simulation type as an input in the CondenserLoop object, and input at least one pressure drop curve on a branch of the plant/condenser loop. This particular output is relevant regardless of the location of pressure drop curves: demand side, supply side, or both.

## **1.21 Group – Plant-Condenser Control**

### **1.21.1 Operation Schemes (Plant and Condenser)**

Plants and condenser loops must have some mechanism for controlling the operation of the loop and which equipment is available under what conditions. Since there may be multiple control schemes that are assigned various priorities associated with each loop, an overall operation scheme must be defined. The overall scheme consists of the object name, an identifying name that is referenced in the main plant or condenser loop statement, and a list of operation schemes. Each operation scheme must have the type of operation scheme, its identifying name, and the schedule that defines its availability. Note that the order in which the individual operation schemes appear in this list defines its priority versus the others with the same scheduled availability. The first scheme appearing in the list is given the highest priority, the second scheme has second highest priority, etc. In other words, if according to its schedule, the first operation scheme is available, then it is used by the simulation to define how the plant or condenser loop operates. If it is not available, the second operation scheme in the list is checked to see if it is available until the highest priority scheme that is also available is found. To allow for simultaneous heating and cooling, there is one configuration where multiple operation schemes are available at a given timestep. This is allowed if a user inputs both a heating range based operation and a cooling range based operation with overlapping schedules. The simulation will look at the current loop demand to determine if the cooling scheme should be used or the heating scheme. In other cases, if two schemes overlap (are available at the same time), a fatal error will be encountered.

### **1.21.2 PlantEquipmentOperationSchemes**

#### **1.21.2.1 Field: Name**

This alpha field contains the identifying name given to the Plant Operation Scheme. This name is placed in the Plant Loop object to select this scheme.

#### **1.21.2.2 Field Set: (Component Object Type, Name, Schedule) up to 8**

Operation schemes are listed in "priority" order. Note that each scheme must address the entire load and/or condition ranges for the simulation. The actual one selected for use will be the first that is "Scheduled" on. That is, if control scheme 1 is not "on" and control scheme 2 is -- then control scheme 2 is selected. Only plant equipment should be listed on a Control Scheme for this item.

#### **1.21.2.3 Field: Control Scheme <#> Object Type**

This alpha field contains the keyword for the type of control scheme used. The options for plant control schemes are:

- PlantEquipmentOperation:Uncontrolled
- PlantEquipmentOperation:CoolingLoad
- PlantEquipmentOperation:HeatingLoad
- PlantEquipmentOperation:ComponentSetpoint
- PlantEquipmentOperation:ThermalEnergyStorage
- PlantEquipmentOperation:UserDefined

#### **1.21.2.4 Field: Control Scheme <#> Name**

This alpha field contains the identifying name given to the control scheme. These must be the named versions of the referenced Control Scheme (e.g., a Uncontrolled Loop Operation with this name or a Cooling or Heating Load Range Based Operation with this name).

#### 1.21.2.5 Field: Control Scheme <#> Schedule

This alpha field contains the schedule name for the control scheme. This schedule consists of weeks and days, with the days containing "0 or 1" for each hour of the day. This binary schedule (0 for off, 1 for on) determines if the control scheme is operating for that hour of day or not.

Examples of this statement in two different IDF's:

```
PlantEquipmentOperationSchemes,  
  CW Loop Operation,          !- Name  
  PlantEquipmentOperation:CoolingLoad, ! Control Scheme 1 Object Type  
  Peak Operation,            !- Control Scheme 1 Name  
  On Peak,                   !- Control Scheme 1 Schedule  
  PlantEquipmentOperation:CoolingLoad, ! Control Scheme 2 Object Type  
  Off Peak Operation,        !- Control Scheme 2 Name  
  Off Peak;                  !- Control Scheme 2 Schedule
```

```
PlantEquipmentOperationSchemes,  
  CW Loop Operation,          !- Name  
  PlantEquipmentOperation:CoolingLoad, ! Control Scheme 1 Object Type  
  Central Chiller Only,      !- Control Scheme 1 Name  
  PlantOnSched;              !- Control Scheme 1 Schedule
```

In the first IDF example, "PlantEquipmentOperation:CoolingLoad" is the type of control scheme. "Peak Operation" and "Off Peak Operation" are the names of two different load range based controls defined separately (see below --). "On Peak" and "Off Peak" are schedules defined elsewhere in the input file.

The load range based operation scheme has two statements associated with it: a main statement that defines the ranges that individual priority settings are valid and the lists of equipment that may be used for each range.

### 1.21.3 CondenserEquipmentOperationSchemes

#### 1.21.3.1 Field: Name

This alpha field contains the identifying name given to the Condenser Operation Scheme.

#### 1.21.3.2 Field Set: (Component Object Type, Name, Schedule) up to 8

Operation schemes are listed in "priority" order. Note that each scheme must address the entire load and/or condition ranges for the simulation. The actual one selected for use will be the first that is "Scheduled" on. That is, if control scheme 1 is not "on" and control scheme 2 is -- then control scheme 2 is selected. Only condenser equipment should be listed on a Control Scheme for this item.

#### 1.21.3.3 Field: Control Scheme <#> Object Type

This alpha field contains the keyword for the type of control scheme used. The options for plant control schemes are:

This alpha field contains the keyword for the type of control scheme used. Currently, the available options are:

- PlantEquipmentOperation:Uncontrolled
- PlantEquipmentOperation:CoolingLoad
- PlantEquipmentOperation:HeatingLoad
- PlantEquipmentOperation:OutdoorDryBulb
- PlantEquipmentOperation:OutdoorWetBulb
- PlantEquipmentOperation:OutdoorDewpoint
- PlantEquipmentOperation:OutdoorRelativeHumidity
- PlantEquipmentOperation:OutdoorDryBulbDifference
- PlantEquipmentOperation:OutdoorWetBulbDifference
- PlantEquipmentOperation:OutdoorDewpointDifference
- PlantEquipmentOperation:UserDefined

The condenser operation schemes apply to the equipment on the 'supply side' of the condenser loop—pumps, cooling towers, ground coupled heat exchangers, etc. The keywords select the algorithm that will be used to determine which equipment is available for each timestep. The Load Schemes schemes select a user

specified set of equipment for each user specified range of a particular simulation variable. Load schemes compare the demand on the condenser supply side with specified load ranges and associated equipment lists. Outdoor schemes compare the current value of an environmental parameter with user specified ranges of that parameter.

#### 1.21.3.4 Field: Control Scheme <#> Name

This alpha field contains the identifying name given to the control scheme.

#### 1.21.3.5 Field: Control Scheme <#> Schedule

This alpha field contains the schedule name for the control scheme. This schedule consists of weeks and days, with the days containing "0 or 1" for each hour of the day. This binary schedule (0 for off, 1 for on) determines which control scheme is operating for a particular hour. The schedule facilitates daily or seasonal changes in control schemes to meet demand side management or energy conservation goals.

Scheduling conflicts are handled by selecting the first available scheme in order of appearance in the list.

Examples of this statement in two IDF's:

```
CondenserEquipmentOperationSchemes,  
  Tower Loop Operation,      !- CondenserOperationSchemeName  
  PlantEquipmentOperation:CoolingLoad, Control Scheme 1 Object Type  
  Year Round Tower Operation, !- Control Scheme 1 Name  
  PlantOnSched;              !- Control Scheme 1 Schedule
```

```
CondenserEquipmentOperationSchemes,Tower Loop Operation,  
  PlantEquipmentOperation:CoolingLoad, Peak Load Operation, AFTERNOONSCHEDULE,  
  PlantEquipmentOperation:CoolingLoad, OffPeak Load Operation, MORNINGSCHEDULE,  
  PlantEquipmentOperation:OutdoorWetBulb, NightOperation, NIGHTSCHEDULE;
```

Each schedule (AFTERNOONSCHEDULE, MORNINGSCHEDULE, NIGHTSCHEDULE) invokes its associated operation scheme (Peak Load Operation, OffPeak Load Operation, NightOperation). The type of operation scheme and its name references the input syntax associated with the range specification and the associated equipment.

### 1.21.4 PlantEquipmentOperation:Uncontrolled

Uncontrolled loop operation simply specifies a group of equipment that runs 'uncontrolled'. If the loop runs, this equipment will run also, unless turned off by the loop flow resolver to maintain continuity in the fluid loop.

#### 1.21.4.1 Field: Name

This alpha field contains the identifying name for the control scheme.

#### 1.21.4.2 Field: Equipment List Name

This alpha field contains the identifying name for the Equipment List. This field ties to the Load Range Equipment List input structure, which must also be defined.

#### 1.21.4.3 Field: Equipment List Name

This alpha field contains the identifying name for the Equipment List. This field ties to the PlantEquipmentList or CondenserEquipmentList input structure, which must also be defined.

### 1.21.5 PlantEquipmentOperation:CoolingLoad

### 1.21.6 PlantEquipmentOperation:HeatingLoad

The PlantEquipmentOperation:CoolingLoad and PlantEquipmentOperation:HeatingLoad objects define the different ranges and which equipment list is valid for each range. After the keyword and the identifying name, a series of data trios is expected. In each trio, there is a lower limit for the load range, an upper limit for the load range, and a name that links to an equipment availability list (the PlantEquipmentList or CondenserEquipmentList objects).

#### 1.21.6.1 Field: Name

This alpha field contains the identifying name for the control scheme.

#### 1.21.6.2 Field Set: (Lower limit, Upper Limit, Equip List name) up to 10

#### 1.21.6.3 Field: Load Range <#> Lower Limit

This numeric field contains the lower demand range (W) for the equipment list. If demand is below this value, then this equipment list will not turn on to meet the demand.

#### 1.21.6.4 Field: Load Range <#> Upper Limit

This numeric field contains the upper demand range (W) for the equipment list. If demand is above this value, then this equipment list will not turn on to meet the demand.

#### 1.21.6.5 Field: Range <#> Equipment List Name

This alpha field contains the identifying name for the Equipment List (i.e., the name of a PlantEquipmentList or CondenserEquipmentList object).

An example of these statements in an IDF is:

```
PlantEquipmentOperation:CoolingLoad, Peak Operation,
    0,7000, Chiller Plant,
    7000,24500, Chiller Plant and Purchased,
    24500,500000, Purchased Only;
```

This particular load based operation scheme (above) has three different ranges. "Chiller Plant", "Chiller Plant and Purchased", and "Purchased Only" are names which link to various PlantEquipmentList or CondenserEquipmentList objects as described below. Gaps may be left in the load ranges specified, but to operate equipment over the entire range the upper limit of a given range must equal the lower limit of the next range as shown in the example. If gaps are left in the load ranges specified, a warning message will be issued when the load to be met falls within a load range "gap". If the user wishes to leave a load range "gap" for a specific reason (no equipment to operate on this plant [or condenser] loop within this load range) and does not want the warning messages to be generated, then specify a lower limit, upper limit and equipment list name for the gap and do not specify any equipment in the associated equipment list, as shown below.

```
PlantEquipmentOperation:CoolingLoad, Peak Operation,
    0,7000, Chiller Plant,
    7000,7100, NoEquipmentOperationOnThisPlantLoop,
    7100,24500, Chiller Plant and Purchased,
    24500,500000, Purchased Only;
```

```
PlantEquipmentList,
    Chiller Plant,           !- Name
    Chiller:Electric,       !- Equipment 1 Object Type
    Big Chiller;            !- Equipment 1 Name
```

```
PlantEquipmentList,
    NoEquipmentOperationOnThisPlantLoop;    !- Name
```

```
PlantEquipmentList,
    Chiller Plant and Purchased, !- Name
    Chiller:Electric,           !- Equipment 1 Object Type
    Big Chiller,                !- Equipment 1 Name
    DistrictCooling,            !- Equipment 2 Object Type
    Purchased Cooling;          !- Equipment 2 Name
```

```
PlantEquipmentList,
    Purchased Only,            !- Name
    DistrictCooling,           !- Equipment 1 Object Type
    Purchased Cooling;         !- Equipment 1 Name
```

#### 1.21.7 PlantEquipmentOperation:OutdoorDryBulb

#### 1.21.8 PlantEquipmentOperation:OutdoorWetBulb

#### 1.21.9 PlantEquipmentOperation:OutdoorRelativeHumidity

#### 1.21.10 PlantEquipmentOperation:OutdoorDewpoint

The outdoor operation objects define the different ranges of the various environmental parameters and which equipment list is valid for each range. After the keyword and the identifying name, a series of data trios is expected. In each trio, there is a lower limit for the load range, an upper limit for the load range, and a name that links to an equipment availability list (the CondenserEquipmentList).

The fields for each of these are:

##### 1.21.10.1 Field: Name

This alpha field contains the identifying name for the control scheme.

##### 1.21.10.2 Field Set: (Lower limit, Upper Limit, Equip List name) up to 10

##### 1.21.10.3 Field: <specific type> Range <#> Lower Limit

This numeric field contains the lower limit (C for temperature operations, Percent for relative humidity operations) for the equipment list. If specific value is below this value, then this equipment list will not turn on to meet the demand.

#### **1.21.10.4 Field: <specific type> Range <#> Upper Limit**

This numeric field contains the lower limit (C for temperature operations, Percent for relative humidity operations) for the equipment list. If specific value is above this value, then this equipment list will not turn on to meet the demand.

#### **1.21.10.5 Field: Range <#> Equipment List Name**

This alpha field contains the identifying name for the Equipment List (i.e., the name of a CondenserEquipmentList object).

#### **1.21.11 PlantEquipmentOperation:OutdoorDryBulbDifference**

#### **1.21.12 PlantEquipmentOperation:OutdoorWetBulbDifference**

#### **1.21.13 PlantEquipmentOperation:OutdoorDewpointDifference**

The Delta Temperature based control strategies help to control any condenser equipment based on the difference between a reference node temperature and any environmental temperature. For example a cooling tower can be controlled by a strategy, which looks at the difference between the tower inlet temperature and wet-bulb temperature. A difference range is specified for each equipment list. IDD excerpts are shown below:

##### **1.21.13.1 Field: Name**

This alpha value contains the identifying name of the control strategy. This name appears as 'control scheme name' in Condenser Operation Scheme object.

##### **1.21.13.2 Field: Reference Temperature Node Name**

This alpha value specifies the reference node for the operation scheme identified in the first field.

##### **1.21.13.3 Field Set: (Lower limit, Upper limit, Equipment List)**

##### **1.21.13.4 Field: <specific type> Range <#> Lower Limit**

This numeric field specifies the minimum temperature difference required for the equipment specified in the equipment list to operate.

##### **1.21.13.5 Field: <specific type> Range <#> Upper Limit**

This numeric field specifies the maximum temperature difference below which the equipment specified in the equipment list is available.

##### **1.21.13.6 Field: Range <#> Equipment List Name**

This alpha field contains the identifying name for the Equipment List (i.e., the name of a CondenserEquipmentList object).

#### **1.21.14 PlantEquipmentOperation:ComponentSetpoint**

In addition to load range based control on the plant loop, sequencing the plant components based on the outlet temperature of individual equipment is allowed. This scheme is common to many present-day Energy Management Systems sequencing. In this scheme, the sequencing is done based on the order specified in the control object described below.

##### **1.21.14.1 Field: Name**

This field specifies the name of the operation scheme.

##### **1.21.14.2 Field Set: Equipment Object Type, Name, Demand Calculation Node, Setpoint Node, Flow Rate, Operation Type)**

##### **1.21.14.3 Field: Equipment <#> Object Type**

This field specifies the type of equipment controlled by scheme.

##### **1.21.14.4 Field: Equipment <#> Name**

This field specifies the name of the controlled equipment.

##### **1.21.14.5 Field: Demand Calculation <#> Node Name**

The component demand will be calculated using the difference between the temperature at the demand node and the component set point temperature.

##### **1.21.14.6 Field: Setpoint <#> Node Name**

Each component controlled under temperature based control will have its own set point different from the loop set point. This field specifies component set point

node (Generally its outlet temperatures). This node is acted upon by a SetpointManager in order to obtain the setpoint at any simulation timestep.

#### 1.21.14.7 Field: Component <#> Flow Rate

This numeric field specifies the design flow rate for the component specified in earlier fields. This flow rate is used to calculate the component demand. The field can be set to autosize, if the user wants the program to calculate the design flow. This would generally be set to autosize when the user does not know the component flow rate and does a sizing calculation for the corresponding component.

#### 1.21.14.8 Field: Operation<#> Type

This alpha field specifies the operation mode for the equipment. The equipment can be in any of the three modes viz. Cooling, Heating and Dual. Dual is used when the components both as heating and cooling equipment (for example heat pumps).

And, as an example in an IDF:

```
PlantEquipmentOperationSchemes,
  CW Loop Operation,          !- PlantOperationSchemeName
  PlantEquipmentOperation:ComponentSetpoint, ! Control Scheme 1 Object Type
  Test Scheme,                !- Control Scheme 1 Name
  On;                          !- Control Scheme 1 Schedule

PlantEquipmentOperation:ComponentSetpoint,
  Test Scheme,
  CHILLER:ELECTRIC,          !- Equipment 1 Object Type
  Little Chiller,           !- Equipment 1 Name
  Little Chiller Inlet Node, !- Demand Calculation 1 Node Name
  Little Chiller Outlet Node, !- Setpoint 1 Node Name
  0.0011,                   !- Component 1 Flow Rate
  COOLING,                   !- Operation 1 Type
  CHILLER:ELECTRIC,          !- Equipment 2 Object Type
  Big Chiller,              !- Equipment 2 Name
  Big Chiller Inlet Node,   !- Demand Calculation 2 Node Name
  Big Chiller Outlet Node,  !- Setpoint 2 Node Name
  0.0011,                   !- Component 2 Flow Rate
  COOLING;                  !- Operation 2 Type
```

#### 1.21.15 PlantEquipmentOperation:ThermalEnergyStorage

Users of thermal energy storage, particularly ice storage systems, are often faced with a challenge of specifying input for these systems. Essentially, they have to define various setpoint managers, temperature schedules, etc. in order to make the system functional. This plant/condenser control type simplifies the input somewhat by eliminating both a setpoint manager and a schedule for each piece of equipment that makes up the ice storage system. In fact, this operation scheme internally creates the setpoint managers required by the equipment listed as operated by the scheme defined by this syntax. While the more complex definition is possible and provides more flexibility like hourly variation of setpoint temperatures at the outlet of each piece of equipment, this input provides the most convenient method for making the system to work and assumes a single charging setpoint temperature and a single discharging setpoint temperature. For most systems, this is all that is needed.

##### 1.21.15.1 Field: Name

This field defines the name of the thermal energy (ice) storage plant equipment operation scheme that will be referenced by the PlantEquipmentOperationSchemes list in the plant input.

##### 1.21.15.2 Field: On-Peak Schedule

This field defines the name of an integer schedule that determines when on-peak electric pricing is in effect. This value is used to determine whether or not the ice storage system should be charging the ice storage unit. In the schedule, a value of 1 (or greater) corresponds to being in the on-peak period while any value of 0 or less corresponds to being in the off-peak period.

##### 1.21.15.3 Field: Charging Availability Schedule

This field defines the name of an integer schedule that determines whether or not the system may enter charging mode off-peak. If the current value of the on-peak schedule is "off", then charging can take place if the charging availability schedule is "on". If the on-peak schedule is "off" and charging availability is "off", then charging is not allowed and the chiller and ice storage units controlled by this statement are operating to meet the non-charging chilled water temperature defined by the next input parameter. In this schedule, a value of 1 (or greater) corresponds to "on" when charging is available during an off-peak period while any value of 0 or less corresponds to chillers not being allowed to charge even during off-peak.

##### 1.21.15.4 Field: Non-Charging Chilled Water Temperature

This field defines the chilled water temperature when the ice storage system is NOT in charging mode. During these times, the storage system could be discharging or dormant depending on HVAC load conditions and ice storage controls. This value is used as the setpoint temperature for chillers associated with this plant equipment operation scheme during non-cooling season and during cooling season during the on-peak period. The cooling season and on-peak

periods are defined by schedules reference to input above.

#### 1.21.15.5 Field: Charging Chilled Water Temperature

This field defines the chilled water temperature when the ice storage system is in charging mode. During these times, the chiller is producing a temperature low enough to generate ice in the ice storage unit. This value is used as the setpoint temperature for chillers associated with this plant equipment operation scheme during the cooling season during the off-peak period. The cooling season and on-peak periods are defined by schedules reference to input above.

#### 1.21.15.6 Field Set: (Component Object Type, Name, Demand Calculation Node, Setpoint Node, Flow Rate, Operation Type)

#### 1.21.15.7 Field: Component <#> Object Type

This field specifies the type of equipment controlled by scheme. This must be a thermal energy storage device (simple or detailed ice storage) or a chiller.

#### 1.21.15.8 Field: Component <#> Name

This field specifies the name of the controlled equipment. This name must be defined in the input as a valid ice storage device or chiller.

#### 1.21.15.9 Field: Component <#> Demand Calculation Node Name

The component demand will be calculated using the difference between the temperature at the demand node and the component set point temperature.

#### 1.21.15.10 Field: Component <#> Setpoint Node Name

Each component controlled under temperature based control will have its own set point different from the loop set point. This field specifies component set point node (Generally its outlet temperatures). This node is acted upon by a SetpointManager in order to obtain the setpoint at any simulation timestep.

#### 1.21.15.11 Field: Component <#> Flow Rate

This numeric field specifies the design flow rate for the component specified in earlier fields. This flow rate is used to calculate the component demand. The field can be set to autosize, if the user wants the program to calculate the design flow. This would generally be set to autosize when the user does not know the component flow rate and does a sizing calculation for the corresponding component.

#### 1.21.15.12 Field: Component <#> Operation Type

This alpha field specifies the operation mode for the equipment. The equipment can be in any of the three modes viz. Cooling, Heating and Dual. Dual is used when the components both as heating and cooling equipment (for example heat pumps). Ice storage units can potentially either heat or cool the circulating fluid and thus should be defined as Dual mode.

An example IDF is shown below:

```
PlantEquipmentOperationSchemes,
  CW Loop Operation,           !- Name
  PlantEquipmentOperation:ThermalEnergyStorage, !- Control Scheme 1 Object Type
  Chiller and Partial Ice Storage, !- Control Scheme 1 Name
  PlantOnSched;                !- Control Scheme 1 Schedule Name

PlantEquipmentOperation:ThermalEnergyStorage,
  Chiller and Partial Ice Storage, !- Name
  OnPeakEnergy,                  !- On-Peak Schedule Name
  ChargingAvail,                 !- Charging Availability Schedule Name
  7.22,                          !- Non-charging Chilled Water Temperature
  -5.0,                          !- Charging Chilled Water Temperature
  Chiller:Electric,              !- Component 1 Object Type
  Central Chiller,               !- Component 1 Name
  Central Chiller Inlet Node,     !- Component 1 Demand Calculation Node Name
  Central Chiller Outlet Node,    !- Component 1 Setpoint Node Name
  autosize,                      !- Component 1 Flow Rate {m3/s}
  COOLING,                       !- Component 1 Operation Type
  ThermalStorage:Ice:Detailed,   !- Component 2 Object Type
  Ice Tank,                      !- Component 2 Name
  Ice Tank Inlet Node,           !- Component 2 Demand Calculation Node Name
  Ice Tank Outlet Node,          !- Component 2 Setpoint Node Name
  0.13506E-02,                  !- Component 2 Flow Rate {m3/s}
  DUAL;                          !- Component 2 Operation Type
```

#### 1.21.16 PlantEquipmentList

#### 1.21.17 CondenserEquipmentList

The PlantEquipmentList and CondenserEquipmentList specify available plant and condenser loop equipment respectively for any loop operation scheme. Each statement contains the object name, an identifying name (which links the definition back to one of the operation scheme statements) and a variable length of data

pairs. These pairs refer to a plant equipment type and an identifying name. The type in this list of pairs must correspond to a valid plant object as described in the next subsection.

Note: If a `PlantEquipmentList` or `CondenserEquipmentList` object is specified with no equipment object types or equipment names, then the corresponding `PlantEquipmentOperation:*` object will assume all available equipment on this plant (or condenser) loop should be OFF (not operate) within the specified lower/upper limit.

#### 1.21.17.1 Field: Name

This alpha field contains the identifying name for the Equipment List.

#### 1.21.17.2 Field Set: (Object Type, Name) up to 10

Remember the order of equipment on this list determines operation priority. Equipment on the list first will try to meet demand first. These fields tie to the Equipment Definition input structure, which must also be defined.

#### 1.21.17.3 Field: Equipment <#> Object Type

This alpha field contains the keyword for the type of equipment in operation. Example: (Chiller:Electric, DistrictCooling). The full list of allowable plant equipment is valid plant objects as described in the next subsection.

#### 1.21.17.4 Field: Equipment <#> Name

This alpha field contains the identifying name for the equipment in operation. This distinguishes between two different pieces of equipment of the same type.

An example of this statement in an IDF is:

```
PlantEquipmentList, Chiller Plant and Purchased,  
    Chiller:Electric, Big Chiller,  
    DistrictCooling, Purchased Cooling;
```

Note that this list is the middle range defined in the `PlantEquipmentOperation:CoolingLoad` statement named "Peak Operation" above. This defines the equipment available when the load encountered by the plant (chiller water demand, for example) is between 7000 W and 24500 W. EnergyPlus will run the "Big Chiller" first up to its capacity and then attempt to meet the remaining load (while in that range) with the next piece of equipment (in this case, "Purchased:Cooling") in the list.

## 1.22 Group – Plant Equipment

### 1.22.1 Equipment Types

In each `PlantEquipmentList` described using the above syntax, various equipment types and names must be given. Each type-name pair must then have a corresponding equipment definition. This subsection lists the various equipment types that are available and examples from an IDF. Where appropriate, notes and comments on the input structure are provided.

### 1.22.2 Generic Chiller Outputs

Many output variable names are common across all chiller types. These generic chiller output names all begin with the word "Chiller". Certain chiller types have additional output variables which are specific to that type of chiller. Chiller energy use is added to the appropriate plant-level meters as a cooling end-use.

- HVAC,Average,Chiller Electric Power [W]
- HVAC,Sum,Chiller Electric Energy [J]
- Zone,Meter,Electricity:Plant [J]
- Zone,Meter,Cooling:Electricity [J]
- HVAC,Average,Chiller Evaporator Cooling Rate [W]
- HVAC,Sum,Chiller Evaporator Cooling Energy [J]
- Zone,Meter,EnergyTransfer:Plant [J]
- Zone,Meter,Chillers:EnergyTransfer [J]
- HVAC,Average,Chiller Evaporator Inlet Temperature [C]
- HVAC,Average,Chiller Evaporator Outlet Temperature [C]
- HVAC,Average,Chiller Evaporator Mass Flow Rate [kg/s]

- HVAC,Average,Chiller Condenser Heat Transfer Rate [W]
- HVAC,Sum,Chiller Condenser Heat Transfer Energy [J]
- Zone,Meter,HeatRejection:EnergyTransfer [J]
- HVAC,Average,Chiller COP [W/W]

The following output is applicable only for air-cooled or evap-cooled chillers

- HVAC,Average,Chiller Condenser Inlet Temperature [C]

The following outputs are applicable only for evap-cooled chillers

- HVAC,Average,Chiller Basin Heater Electric Power [W]
- HVAC,Average,Chiller Basin Heater Electric Energy [J]

The following three outputs are only available for water-cooled chillers

- HVAC,Average,Chiller Condenser Inlet Temperature [C]
- HVAC,Average,Chiller Condenser Outlet Temperature [C]
- HVAC,Average,Chiller Condenser Mass Flow Rate [kg/s]
- HVAC,Average,Chiller Drive Shaft Power [W]
- HVAC,Sum,Chiller Drive Shaft Energy [J]
- Zone,Meter,HeatRecovery:EnergyTransfer [J]
- HVAC,Average,Chiller Lube Recovered Heat Rate [W]

#### **1.22.2.1 Chiller Electric Power [W]**

#### **1.22.2.2 Chiller Electric Energy [J]**

These outputs are the electric power input to the chiller. In the case of steam or fuel-powered chillers, this represents the internal chiller pumps and other electric power consumption. Consumption is metered on Cooling:Electricity, Electricity:Plant, and Electricity:Facility.

#### **1.22.2.3 Chiller Evaporator Cooling Rate [W]**

#### **1.22.2.4 Chiller Evaporator Cooling Energy [J]**

These outputs are the evaporator heat transfer which is the cooling delivered by the chiller. Chiller Evaporator Cooling Energy is metered on Chillers:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

#### **1.22.2.5 Chiller Evaporator Inlet Temperature [C]**

#### **1.22.2.6 Chiller Evaporator Outlet Temperature [C]**

#### **1.22.2.7 Chiller Evaporator Mass Flow Rate [kg/s]**

These outputs are the evaporator (chilled water) inlet and outlet temperatures and flow rate.

#### **1.22.2.8 Chiller COP [W/W]**

This output is the coefficient of performance for the chiller during cooling operation. It is calculated as the evaporator heat transfer rate (Chiller Evaporator Cooling Rate) divided by the “fuel” consumption rate by the chiller. For the constant COP and electric chillers, the “fuel” is electricity so the divisor is Chiller Electric Power [W]. For the absorption chiller, the “fuel” is steam so the divisor is Steam Consumption Rate [W].

*Note that this variable is reported as zero when the chiller is not operating. When reported for frequencies longer than "detailed" (such as timestep, hourly, daily, monthly or environment), this output will only be meaningful when the chiller is operating for the entire reporting period. To determine an average COP for a longer time period, compute the COP based on total evaporator heat transfer divided by total electric or fuel input over the desired period.*

#### **1.22.2.9 Chiller Part Load Ratio**

This output is the operating part-load ratio of the indirect absorption chiller. This output may fall below the minimum part-load ratio specified in the input. For this case, the Chiller Cycling Ratio is used to further define the performance of the indirect absorption chiller.

#### **1.22.2.10 Chiller Cycling Ratio**

This output is the fraction of the timestep the indirect absorption chiller operates. When the chiller operates above the minimum part-load ratio, a Chiller Cycling Ratio of 1 is reported. When the chiller operates below the minimum part-load ratio, the Chiller Cycling Ratio reports the fraction of the timestep the indirect absorption chiller operates.

#### **1.22.2.11 Chiller Condenser Heat Transfer Rate [W]**

#### **1.22.2.12 Chiller Condenser Heat Transfer Energy [J]**

These outputs are the condenser heat transfer which is the heat rejected from the chiller to either a condenser water loop or through an air-cooled condenser. Chiller Condenser Heat Transfer Energy is metered on HeatRejection:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

#### **1.22.2.13 Chiller Condenser Inlet Temperature [C]**

This output is the condenser (heat rejection) inlet temperature for air-cooled or evap-cooled chillers. For an air-cooled chiller, this output would be the dry-bulb temperature of the air entering the condenser coil. For an evap-cooled chiller, this output would be the wet-bulb temperature of the air entering the evaporatively-cooled condenser coil.

#### **1.22.2.14 Chiller Basin Heater Electric Power [W]**

#### **1.22.2.15 Chiller Basin Heater Electric Energy [J]**

These outputs are the electric power input to the chiller's basin heater (for evaporatively-cooled condenser type). Consumption is metered on Chillers:Electricity, Electricity:Plant, and Electricity:Facility

#### **1.22.2.16 Chiller Condenser Inlet Temperature [C]**

#### **1.22.2.17 Chiller Condenser Outlet Temperature [C]**

#### **1.22.2.18 Chiller Condenser Mass Flow Rate [kg/s]**

These outputs are the condenser (heat rejection) inlet and outlet temperatures and flow rate for water-cooled chillers.

#### **1.22.2.19 Chiller Drive Shaft Power [W]**

#### **1.22.2.20 Chiller Drive Shaft Energy [J]**

For engine-driven and turbine-driven chillers, these outputs are the shaft power produced by the prime mover and transferred to the chiller compressor.

#### **1.22.2.21 Chiller Lube Recovered Heat Rate [W]**

#### **1.22.2.22 Chiller Lube Recovered Heat Energy [J]**

#### **1.22.2.23 Chiller Jacket Recovered Heat Rate [W]**

#### **1.22.2.24 Chiller Jacket Recovered Heat Energy [J]**

#### 1.22.2.25 Chiller Exhaust Recovered Heat Rate [W]

#### 1.22.2.26 Chiller Exhaust Recovered Heat Energy [J]

#### 1.22.2.27 Chiller Total Recovered Heat Rate [W]

#### 1.22.2.28 Chiller Total Recovered Heat Energy [J]

For chillers with heat recovery, such as engine-driven chillers, these outputs are the components of recoverable energy available. For a given chiller type, one or more of the following components may be applicable: Lube (engine lubricant), Jacket (engine coolant), Exhaust (engine exhaust), and Total. Chiller Lube Recovered Heat Energy, Chiller Jacket Recovered Heat Energy, and Chiller Exhaust Heat Recovery Energy are metered on HeatRecovery:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

#### 1.22.2.29 Chiller Exhaust Temperature [C]

This is the exhaust temperature leaving an engine chiller.

#### 1.22.2.30 Chiller Heat Recovery Inlet Temperature [C]

#### 1.22.2.31 Chiller Heat Recovery Outlet Temperature [C]

#### 1.22.2.32 Chiller Heat Recovery Mass Flow Rate [kg/s]

These outputs are the heat recovery inlet and outlet temperatures and flow rate for chillers with heat recovery such as engine-driven and gas turbine chillers.

#### 1.22.2.33 Chiller Effective Heat Rejection Temperature [C]

This output variable is available for heat recovery chillers that model split bundle condenser. The condenser fluid temperatures used to characterize chiller performance are modified to account for the temperature of the heat recovery fluid. This output is the resulting temperature used for characterizing chiller performance and is a blend of the temperatures in the condenser and heat recovery fluid streams. For the Chiller:Electric and Chiller:Electric:EIR models, this is an effective inlet temperature while for the Chiller:Electric:ReformulatedEIR model, this is an effective outlet temperature.

#### 1.22.2.34 Chiller <Fuel Type> Rate [W]

#### 1.22.2.35 Chiller <Fuel Type> Energy [J]

#### 1.22.2.36 Chiller <Fuel Type> Mass Flow Rate [kg/s]

#### 1.22.2.37 Chiller Gas Mass [kg] (Gas Turbine Chiller only)

These outputs are the steam or fuel input for steam or fuel-fired chillers. Valid fuel types depend on the type of chiller. <Fuel Type> may be one of: Gas (natural gas), Steam, Propane, Diesel, Gasoline, FuelOil#1, FuelOil#2, OtherFuel1 and OtherFuel2. Consumption is metered on Cooling:<Fuel Type>, <Fuel Type>:Plant, and <Fuel Type>:Facility.

#### 1.22.2.38 Chiller Source Hot Water Rate [W]

#### 1.22.2.39 Chiller Source Hot Water Energy [J]

#### 1.22.2.40 Chiller Source Steam Rate [W]

### 1.22.3 Chiller:Absorption

#### 1.22.3.1 Field: Name

This alpha field contains the identifying name for the absorption chiller.

#### 1.22.3.2 Field: Nominal Capacity

This numeric field contains the nominal cooling capability of the chiller in Watts.

#### 1.22.3.3 Field: Nominal Pumping Power

This numeric field contains the nominal pumping power of the absorber in Watts.

#### 1.22.3.4 Field: Chilled Water Inlet Node Name

This required alpha field contains the identifying name for the absorption chiller plant side inlet node.

#### 1.22.3.5 Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the absorption chiller plant side outlet node.

#### 1.22.3.6 Field: Condenser Inlet Node Name

This required alpha field contains the identifying name for the absorption chiller condenser side inlet node.

#### 1.22.3.7 Field: Condenser Outlet Node Name

This required alpha field contains the identifying name given to the Heat Recovery Loop Component Outlet Node.

#### 1.22.3.8 Field: Minimum Part Load Ratio

This numeric field contains the absorption chiller's minimum part load ratio. The expected range is between 0 and 1. The minimum part load is not the load where the machine shuts off, but where the amount of power remains constant to produce smaller loads than this fraction.

#### 1.22.3.9 Field: Maximum Part Load Ratio

This numeric field contains the absorption chiller's maximum part load ratio. This value may exceed 1, but the normal range is between 0 and 1.1.

#### 1.22.3.10 Field: Optimum Part Load Ratio

This numeric field contains the absorption chiller's optimum part load ratio. This is the part load ratio at which the chiller performs at its maximum COP.

#### 1.22.3.11 Field: Design Condenser Inlet Temperature

This numeric field contains the absorption chiller's condenser inlet design temperature in Celsius.

#### 1.22.3.12 Field: Design Chilled Water Flow Rate

For variable volume chiller this is the maximum flow and for constant flow chiller this is the design flow rate. The units are in cubic meters per second.

#### 1.22.3.13 Field: Design Condenser Water Flow Rate

This numeric field contains the absorption chiller's design condenser water flow rate in cubic meters per second.

#### 1.22.3.14 Generator Heat Input Part Load Ratio Curve

The Generator Heat Input Part Load Ratio Curve is a quadratic equation that determines the Ratio of the generator load on the absorber to the demand on the chiller. The defining equation is:

$$SteamInputRatio = \frac{C1}{PLR} + C2 + C3 * PLR \quad (37)$$

The following three fields contain the coefficients for the equation.

#### 1.22.3.15 Field: Coefficient 1 of the Steam Use Part Load Ratio Curve

C1 in the Generator Heat Input Part Load Ratio Curve. This value is obtained by fitting manufacturers' performance data to the curve.

#### 1.22.3.16 Field: Coefficient 2 of the Steam Use Part Load Ratio Curve

C2 in the Generator Heat Input Part Load Ratio Curve. This value is obtained by fitting manufacturers' performance data to the curve.

#### 1.22.3.17 Field: Coefficient 3 of the Steam Use Part Load Ratio Curve

C3 in the Generator Heat Input Part Load Ratio Curve. This value is obtained by fitting manufacturers' performance data to the curve.

#### 1.22.3.18 Pump Electric Use Part Load Ratio Curve

The Pump Electric Use Part Load Ratio Curve is a quadratic equation that determines the Ratio of the actual absorber pumping power to the nominal pumping power. The defining equation is:

$$ElectricInputRatio = C1 + C2 * PLR + C3 * PLR^2 \quad (38)$$

The following three fields contain the coefficients for the equation.

#### 1.22.3.19 Field: Coefficient 1 of the Pump Electric Use Part Load Ratio Curve

C1 in the Pump Electric Use Part Load Ratio Curve. This value is obtained by fitting manufacturers' performance data to the curve.

#### 1.22.3.20 Field: Coefficient 2 of the Pump Electric Use Part Load Ratio Curve

C2 in the Pump Electric Use Part Load Ratio Curve. This value is obtained by fitting manufacturers' performance data to the curve.

#### 1.22.3.21 Field: Coefficient 3 of the Pump Electric Use Part Load Ratio Curve

C3 in the Pump Electric Use Part Load Ratio Curve. This value is obtained by fitting manufacturers' performance data to the curve.

#### 1.22.3.22 Field: Chilled Water Outlet Temperature Lower Limit

This numeric field contains the lower limit for the evaporator outlet temperature. This temperature acts as a cut off for heat transfer in the evaporator, so that the fluid doesn't get too cold.

#### 1.22.3.23 Field: Generator Inlet Node Name

This alpha field contains the identifying name given to the Generator Inlet Node. A steam or hot water loop is not required to simulate an absorption chiller. If a steam/hot water loop is used, enter the name of the generator inlet node.

#### 1.22.3.24 Field: Generator Outlet Node Name

This alpha field contains the identifying name given to the Generator Outlet Node. A steam or hot water loop is not required to simulate an absorption chiller. If a steam/hot water loop is used, enter the name of the generator outlet node.

#### 1.22.3.25 Field: Chiller Flow Mode

This choice field determines how the chiller operates with respect to the intended fluid flow through the device's evaporator. There are three different choices for specifying operating modes for the intended flow behavior: "NotModulated," "ConstantFlow," and "LeavingSetpointModulated." NotModulated is useful for either variable or constant speed pumping arrangements where the chiller is passive in the sense that although it makes a nominal request for its design flow rate it can operate at varying flow rates. ConstantFlow is useful for constant speed pumping arrangements where the chiller's request for flow is stricter and can increase the overall loop flow. LeavingSetpointModulated changes the chiller model to internally vary the flow rate so that the temperature leaving the chiller matches a setpoint at the evaporator outlet. For this absorption chiller, this mode also affects the flow rate on the generator connection. In all cases the operation of the external plant system can also impact the flow through the chiller -- for example if the relative sizes and operation are such that flow is restricted and the requests cannot be met. The default, if not specified, is NotModulated. This flow mode does not impact the condenser loop connection.

#### 1.22.3.26 Field: Generator Fluid Type

This choice field specifies the type of fluid used to heat the generator solution. The valid choices are **HotWater** or **Steam**. This field should be specified as Steam or left blank if the generator inlet/outlet nodes are not specified.

#### 1.22.3.27 Field: Design Generator Fluid Flow Rate

This numeric field contains the absorption chiller's design condenser fluid flow rate in cubic meters per second.

#### 1.22.3.28 Field: Degree of Subcooling in Steam Generator

Ideally, the steam trap located at the outlet of the generator should remove all the condensate immediately, however, there is a delay in this process in actual systems which causes the condensate to SubCool by a certain amount before leaving the generator. This amount of subcooling is included in the heat transferred to the solution in the generator. The minimum value is 0° Celsius and default is 5° Celsius. This field is not used when the generator inlet/outlet node are not specified or the generator is connected to a hot water loop.

#### 1.22.3.29 Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Capacity, Nominal Pumping Power, Design Chilled Water Flow Rate, Design Condenser Water Flow Rate and Design Generator Fluid Flow Rate. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

Following is an example input for an Absorption Chiller.

```

- HVAC,Sum, Chiller Source Steam Energy [J]
- HVAC,Average,Chiller Steam Mass Flow Rate [kg/s]

For Chillers with Hot Water Generators:

- HVAC,Average,Chiller Source Hot Water Rate [W]
- HVAC,Sum,Chiller Source Hot Water Energy [J]
- HVAC,Average,Chiller Hot Water Mass Flow Rate [kg/s]

These chiller output variables are defined above under "Generic Chiller Outputs."

### **1.22.5 Chiller:Absorption:Indirect**

The Chiller:Absorption:Indirect object is an enhanced version of the absorption chiller model found in the Building Loads and System Thermodynamics (BLAST) program. This enhanced model is nearly identical to the existing absorption chiller model (Ref. Chiller:Absorption) with the exceptions that: 1) the enhanced indirect absorption chiller model provides more flexible performance curves and 2) chiller performance now includes the impact of varying evaporator, condenser, and generator temperatures. Since these absorption chiller models are nearly identical (i.e., the performance curves of the enhanced model can be manipulated to produce similar results to the previous model), it is quite probable that the Chiller:Absorption model will be deprecated in a future release of EnergyPlus.

#### **1.22.5.1 Field: Name**

This required alpha field contains the identifying name for the indirect absorption chiller.

#### **1.22.5.2 Field: Nominal Capacity**

This required numeric field contains the nominal cooling capability of the chiller in Watts. This field must be greater than 0 and is autosizable.

#### **1.22.5.3 Field: Nominal Pumping Power**

This required numeric field contains the nominal pumping power of the chiller in Watts. The minimum value for this field is 0 and is autosizable.

#### **1.22.5.4 Field: Chilled Water Inlet Node Name**

This required alpha field contains the identifying name for the chiller chilled water inlet node.

#### **1.22.5.5 Field: Chilled Water Outlet Node Name**

This required alpha field contains the identifying name for the chiller chilled water outlet node.

#### **1.22.5.6 Field: Condenser Inlet Node Name**

This required alpha field contains the identifying name for the chiller condenser inlet node.

#### **1.22.5.7 Field: Condenser Outlet Node Name**

This required alpha field contains the identifying name given to the chiller outlet node.

#### **1.22.5.8 Field: Minimum Part Load Ratio**

This numeric field contains the chiller's minimum part-load ratio. The expected range is between 0 and 1. The minimum part load is not the load where the machine shuts off, but where the amount of power remains constant to produce smaller loads than this fraction.

#### **1.22.5.9 Field: Maximum Part Load Ratio**

This numeric field contains the chiller's maximum part-load ratio. This value may exceed 1, but the normal range is between 0 and 1.1.

#### **1.22.5.10 Field: Optimum Part Load Ratio**

This numeric field contains the chiller's optimum part-load ratio. This is the part-load ratio at which the chiller performs at its maximum COP.

#### **1.22.5.11 Field: Design Condenser Inlet Temperature**

This numeric field contains the chiller's condenser inlet design temperature in Celsius. The default value for this field is 30° C and is only used when the Design Chilled Water Flow Rate is autosized.

#### **1.22.5.12 Field: Condenser Inlet Temperature Lower Limit**

This numeric field contains the chiller's lower limit for the condenser entering water temperature in Celsius. The default value for this field is 15° C. If this limit is exceeded, a warning message will report the incident. No correction to chiller capacity is made for low condenser entering water temperatures.

#### **1.22.5.13 Field: Chilled Water Outlet Temperature Lower Limit**

This numeric field contains the chiller's lower limit for the evaporator leaving water temperature in Celsius. The default value for this field is 5° C. If this limit is exceeded, a warning message will report the incident. No correction to chiller capacity is made for low evaporator leaving water temperatures.

#### **1.22.5.14 Field: Design Chilled Water Flow Rate**

This numeric input specifies the design evaporator volumetric flow rate in cubic meters per second. The value specified must be greater than 0 or this field is autosizable. For variable volume chiller this is the maximum flow and for constant flow chiller this is the design flow rate.

#### **1.22.5.15 Field: Design Condenser Water Flow Rate**

This numeric field specifies the chiller's design condenser water flow rate in cubic meters per second. The value specified must be greater than 0 or this field is autosizable.

#### **1.22.5.16 Field: Chiller Flow Mode**

This choice field determines how the chiller operates with respect to the intended fluid flow through the device's evaporator. There are three different choices for specifying operating modes for the intended flow behavior: "NotModulated," "ConstantFlow," and "LeavingSetpointModulated." NotModulated is useful for either variable or constant speed pumping arrangements where the chiller is passive in the sense that although it makes a nominal request for its design flow rate it can operate at varying flow rates. ConstantFlow is useful for constant speed pumping arrangements where the chiller's request for flow is stricter and can increase the overall loop flow. LeavingSetpointModulated changes the chiller model to internally vary the flow rate so that the temperature leaving the chiller matches a setpoint at the evaporator outlet. For this absorption chiller, this mode also affects the flow rate on the generator connection. In all cases the operation of the external plant system can also impact the flow through the chiller -- for example if the relative sizes and operation are such that flow is restricted and the requests cannot be met. The default, if not specified, is NotModulated. This flow mode does not impact the condenser loop connection.

#### **1.22.5.17 Field: Generator Heat Input Function of Part Load Ratio Curve Name**

This required alpha field specifies the name of the curve used to determine the heat input to the chiller. The curve is a quadratic or cubic curve which characterizes the heat input as a function of chiller part-load ratio. The curve output is multiplied by the chiller's nominal capacity and operating part-load ratio or minimum part-load ratio, whichever is greater, to determine the amount of heat input required for the given operating conditions.

#### **1.22.5.18 Field: Pump Electric Input Function of Part Load Ratio Curve Name**

This alpha field specifies the name of the curve used to determine the pump electrical input to the chiller. The curve is a quadratic or cubic curve which characterizes the pump electrical power as a function of chiller part-load ratio. The curve output is multiplied by the chiller's nominal pumping power and operating part-load ratio or minimum part-load ratio, whichever is greater, to determine the amount of pumping power required for the given operating conditions.

#### **1.22.5.19 Field: Generator Inlet Node Name**

This alpha field contains the identifying name given to the Generator Inlet Node. A steam or hot water loop is not required to simulate an indirect absorption chiller. If a steam/hot water loop is used, enter the name of the generator inlet node.

#### **1.22.5.20 Field: Generator Outlet Node Name**

This alpha field contains the identifying name given to the Generator Outlet Node. A steam or hot water loop is not required to simulate an indirect absorption chiller. If a steam/hot water loop is used, enter the name of the generator outlet node.

#### **1.22.5.21 Field: Capacity Correction Function of Condenser Temperature Curve Name**

This alpha field specifies the name of a quadratic or cubic curve which correlates the chiller's evaporator capacity as a function of condenser entering water temperature. This curve is used to correct nominal capacity at off-design condensing temperatures.

#### **1.22.5.22 Field: Capacity Correction Function of Chilled Water Temperature Curve Name**

This alpha field specifies the name of a quadratic or cubic curve which correlates the chiller's evaporator capacity as a function of evaporator leaving water temperature. This curve is used to correct nominal capacity at off-design evaporator temperatures.

#### **1.22.5.23 Field: Capacity Correction Function of Generator Temperature Curve Name**

This alpha field specifies the name of a quadratic or cubic curve which correlates the chiller's evaporator capacity as a function of generator entering water temperature. This curve is used to correct nominal capacity at off-design evaporator temperatures and is only used when the Generator Fluid Type is specified as Hot Water.

#### **1.22.5.24 Field: Generator Heat Input Correction Function of Condenser Temperature Curve Name**

This alpha field specifies the name of a quadratic or cubic curve which correlates the chiller's heat input as a function of condenser entering water temperature. This curve is used to correct generator heat input at off-design condensing temperatures.

#### **1.22.5.25 Field: Generator Heat Input Correction Function of Chilled Water Temperature Curve Name**

This alpha field specifies the name of a quadratic or cubic curve which correlates the chiller's heat input as a function of evaporator leaving water temperature. This curve is used to correct generator heat input at off-design evaporator temperatures.

#### **1.22.5.26 Field: Generator Heat Source Type**

This choice field specifies the type of fluid used to heat the generator solution. The valid choices are **HotWater** or **Steam**. This input is used to identify the

method used to calculate the generator mass flow rate. This field is not used if the generator inlet/outlet nodes are not specified. The default value is Steam.

#### 1.22.5.27 Field: Design Generator Fluid Flow Rate

This numeric field specifies the chiller's design generator *fluid* flow rate in cubic meters per second. The value specified must be greater than 0 or this field is autosizable. For variable flow chillers this is the maximum generator flow rate, for constant flow chillers this is the flow rate.

#### 1.22.5.28 Field: Temperature Lower Limit Generator Inlet

This numeric field specifies the lower limit of the generator's entering water temperature. This field is not used if the Generator Fluid Type is specified as steam.

#### 1.22.5.29 Field: Degree of Subcooling in Steam Generator

Ideally the steam trap located at the outlet of generator should remove all the condensate immediately, however there is a delay in this process in actual systems which causes the condensate to SubCool by a certain degree before leaving the generator. This amount of subcooling is included in the heat transferred to the solution in the generator. The minimum value is 0° Celsius, the maximum value is 20° Celsius, and the default is 1° Celsius.

#### 1.22.5.30 Field: Degree of Subcooling in Steam Condensate Loop

This essentially represents the heat loss to the atmosphere due to uninsulated condensate return piping to the boiler. Condensate return piping operates at atmospheric pressure and is not insulated. The condensate sub cools to certain degree before it is pumped back to the boiler. The minimum value is 0° Celsius and the default is 0° Celsius.

#### 1.22.5.31 Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Capacity, Nominal Pumping Power, Design Chilled Water Flow Rate, Design Condenser Water Flow Rate and Design Generator Fluid Flow Rate. Sizing factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

Following is an example input for an Absorption Chiller.

```
Chiller:Absorption:Indirect,
  Big Chiller,                !- Chiller Name
  100000,                     !- Nominal Capacity {W}

  12.0;                      !- Degree of Subcooling in Steam Condensate Loop {C}
```

### 1.22.6 Indirect Absorption Chiller Outputs

- HVAC,Average,Chiller Electric Power [W]
- HVAC,Sum,Chiller Electric Energy [J]
- Zone,Meter,Electricity:Plant [J]
- Zone,Meter,Cooling:Electricity [J]

- HVAC,Average,Chiller Evaporator Cooling Rate [W]
- HVAC,Sum,Chiller Evaporator Cooling Energy [J]
- Zone,Meter,EnergyTransfer:Plant [J]
- Zone,Meter,Chillers:EnergyTransfer [J]
- HVAC,Average,Chiller Evaporator Inlet Temperature [C]
- HVAC,Average,Chiller Evaporator Outlet Temperature [C]
- HVAC,Average,Chiller Evaporator Mass Flow Rate [kg/s]
- HVAC,Average,Chiller Condenser Heat Transfer Rate [W]
- HVAC,Sum,Chiller Condenser Heat Transfer Energy [J]
- Zone,Meter,HeatRejection:EnergyTransfer [J]
- HVAC,Average,Chiller Condenser Inlet Temperature [C]
- HVAC,Average,Chiller Condenser Outlet Temperature [C]
- HVAC,Average,Chiller Condenser Mass Flow Rate [kg/s]
- HVAC,Average,Chiller COP [W/W]
- HVAC,Average,Chiller Part-Load Ratio
- HVAC,Average,Chiller Cycling Ratio

For Chillers with Steam Generators:

- HVAC,Average, Chiller Source Steam Rate [W]
- HVAC,Sum, Chiller Source Steam Energy [J]
- Zone,Meter,[Steam:Plant](#) [J]
- Zone,Meter,Cooling:Steam [J]
- HVAC,Average, Chiller Steam Mass Flow Rate [kg/s]
- HVAC,Average, Chiller Steam Heat Loss Rate [W]

For Chillers with Hot Water Generators:

- HVAC,Average, Chiller Source Hot Water Rate [W]
- HVAC,Sum, Chiller Source Hot Water Energy [J]
- Zone,Meter,EnergyTransfer:Plant [J]
- Zone,Meter,Cooling:EnergyTransfer [J]
- HVAC,Average, Chiller Hot Water Mass Flow Rate [kg/s]

These chiller output variables are defined above under "Generic Chiller Outputs."

### 1.22.7 Chiller:ConstantCOP

This chiller model is based on a simple, constant COP simulation of the chiller. In this case, performance does not vary with chilled water temperature or condenser conditions.

Such a model is useful when the user does not have access to detailed performance data.

#### 1.22.7.1 Field: Name

This alpha field contains the identifying name for the constant COP chiller.

#### 1.22.7.2 Field: Nominal Capacity

This numeric field contains the nominal cooling capability of the chiller in Watts.

### 1.22.7.3 Field: Nominal COP

This numeric field contains the Chiller's coefficient of performance.

### 1.22.7.4 Field: Design Chilled Water Flow Rate

For variable volume chiller this is the maximum flow and for constant flow chiller this is the design flow rate. The units are in cubic meters per second.

### 1.22.7.5 Field: Design Condenser Water Flow Rate

This numeric field contains the electric chiller's design condenser water flow rate in cubic meters per second. This field is autosizable. This field is not used for Condenser Type = AirCooled or EvaporativelyCooled.

### 1.22.7.6 Field: Chilled Water Inlet Node Name

This required alpha field contains the identifying name for the constant COP chiller plant side inlet node.

### 1.22.7.7 Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the constant COP chiller plant side outlet node.

### 1.22.7.8 Field: Condenser Inlet Node Name

This alpha field contains the identifying name for the constant COP chiller condenser side inlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and a condenser inlet node name is specified here, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates an outdoor air node and the air temperature information on this node is taken directly from the weather file (no node height adjustment).

### 1.22.7.9 Field: Condenser Outlet Node Name

This alpha field contains the identifying name for the constant COP chiller condenser side outlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates a condenser side outlet air node.

### 1.22.7.10 Field: Condenser Type

This alpha field determines what type of condenser will be modeled with this chiller. The 3 type of condensers are AirCooled, WaterCooled, and EvaporativelyCooled with the default being AirCooled if not specified. AirCooled and EvaporativelyCooled do not require a CondenserLoop to be specified, whereas the WaterCooled option requires the full specification of the CondenserLoop and its associated equipment.

### 1.22.7.11 Field: Chiller Flow Mode

This choice field determines how the chiller operates with respect to the intended fluid flow through the device's evaporator. There are three different choices for specifying operating modes for the intended flow behavior: "NotModulated," "ConstantFlow," and "LeavingSetpointModulated." NotModulated is useful for either variable or constant speed pumping arrangements where the chiller is passive in the sense that although it makes a nominal request for its design flow rate it can operate at varying flow rates. ConstantFlow is useful for constant speed pumping arrangements where the chiller's request for flow is stricter and can increase the overall loop flow. LeavingSetpointModulated changes the chiller model to internally vary the flow rate so that the temperature leaving the chiller matches a setpoint. In all cases the operation of the external plant system can also impact the flow through the chiller -- for example if the relative sizes and operation are such that flow is restricted and the requests cannot be met. The default, if not specified, is NotModulated.

### 1.22.7.12 Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Capacity, Design Chilled Water Flow Rate and Design Condenser Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

### 1.22.7.13 Field: Basin Heater Capacity

This numeric field contains the capacity of the chiller's electric basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the chiller is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

### 1.22.7.14 Field: Basin Heater Setpoint Temperature

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the chiller is off. This set point temperature must be greater than or equal to 2°C, and the default value is 2°C if this field is left blank.

### 1.22.7.15 Field: Basin Heater Operating Schedule Name

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the chiller is off.

An example of this statement in an IDF is:

```
Chiller:ConstantCOP, Little Chiller,
    25000,          ! Nominal Capacity [W]
    2.5,           ! COP
    0.0011,        ! Design Chilled Water Flow Rate [m3/s]
    0.0011,        ! Design Condenser Water Flow Rate [m3/s]
    Little Chiller Inlet Node, Little Chiller Outlet Node,
    Little Chiller Condenser Inlet Node, Little Chiller Condenser Outlet Node,
    WaterCooled,
    VariableFlow;
```

    0.0011,            !- Design Chilled Water Flow Rate {m3/s}
    0.0011,            !- Design Condenser Water Flow Rate {m3/s}
    Little Chiller Inlet Node,  !- Chilled Water Inlet Node Name
    Little Chiller Outlet Node, !- Chilled Water Outlet Node Name
    Little Chiller Condenser Inlet Node,  !- Condenser Inlet Node Name
    Little Chiller Condenser Outlet Node, !- Condenser Outlet Node Name
    EvaporativelyCooled,      !- Condenser Type
    VariableFlow,            !- Chiller Flow Mode
    ,                        !- Sizing Factor
    450;                     !- Basin Heater Capacity {W/K}
```

### 1.22.8 Constant COP Chiller Outputs

- HVAC,Average,Chiller Electric Power [W]
- HVAC,Sum,Chiller Electric Energy [J]
- Zone,Meter,Electricity:Plant [J]
- Zone,Meter,Cooling:Electricity [J]
- HVAC,Average,Chiller Evaporator Cooling Rate [W]
- HVAC,Sum,Chiller Evaporator Cooling Energy [J]
- Zone,Meter,EnergyTransfer:Plant [J]
- Zone,Meter,Chillers:EnergyTransfer [J]
- HVAC,Average,Chiller Evaporator Inlet Temperature [C]
- HVAC,Average,Chiller Evaporator Outlet Temperature [C]
- HVAC,Average,Chiller Evaporator Mass Flow Rate [kg/s]
- HVAC,Average,Chiller Condenser Heat Transfer Rate [W]
- HVAC,Sum,Chiller Condenser Heat Transfer Energy [J]
- Zone,Meter,HeatRejection:EnergyTransfer [J]

Air-cooled or Evap-cooled:

- HVAC,Average,Chiller Condenser Inlet Temperature [C]

Evap-cooled:

- HVAC,Average,Chiller Basin Heater Electric Power [W]
- HVAC,Average,Chiller Basin Heater Electric Energy [J]

Water-cooled:

- HVAC,Average,Chiller Condenser Inlet Temperature [C]
- HVAC,Average,Chiller Condenser Outlet Temperature [C]
- HVAC,Average,Chiller Condenser Mass Flow Rate [kg/s]

These chiller output variables are defined above under "Generic Chiller Outputs."

### 1.22.9 Chiller:Electric

This chiller model is the empirical model from the Building Loads and System Thermodynamics (BLAST) program. Capacity, power, and full load are each defined by a set of performance curves (quadratics). Chiller performance curves are generated by fitting catalog data to third order polynomial equations. The nominal inputs and curves described below are combined as follows to calculate the chiller power:

$$\text{Power} = \text{FracFullLoadPower} \cdot \text{FullLoadPowerRat} \cdot \text{AvailToNominalCapacityRatio} \cdot \frac{\text{NominalCapacity}}{\text{COP}} \quad (39)$$

where:

NominalCapacity = Nominal Capacity field

COP = COP field

AvailToNominalCapacityRatio = the result of the Capacity Ratio Curve

FullLoadPowerRat = the result of the Power Ratio Curve

FracFullLoadPower = the result of the Full Load Ratio Curve

#### 1.22.9.1 Field: Name

This alpha field contains the identifying name for the electric chiller.

#### 1.22.9.2 Field: Condenser Type

This alpha field determines what type of condenser will be modeled with this chiller. The 3 type of condensers are AirCooled, WaterCooled, and EvaporativelyCooled with the default being AirCooled if not specified. AirCooled and EvaporativelyCooled do not require a Condenser Loop to be specified, where the WaterCooled option requires the full specification of the Condenser Loop and its associated equipment.

#### 1.22.9.3 Field: Nominal Capacity

This numeric field contains the nominal cooling capability of the chiller in Watts.

#### 1.22.9.4 Field: Nominal COP

This numeric field contains the chiller's coefficient of performance. For a water-cooled chiller, this number does not include energy use due to condenser pumps and/or fans. For an air-cooled or evap-cooled chiller, this number includes condenser fan power.

#### 1.22.9.5 Field: Chilled Water Inlet Node Name

This required alpha field contains the identifying name for the electric chiller plant side inlet node.

#### 1.22.9.6 Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the electric chiller plant side outlet node.

#### 1.22.9.7 Field: Condenser Inlet Node Name

This alpha field contains the identifying name for the electric chiller condenser side inlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and a condenser inlet node name is specified here, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates an outdoor air node

and the air temperature information on this node is taken directly from the weather file (no node height adjustment).

#### 1.22.9.8 Field: Condenser Outlet Node Name

This alpha field contains the identifying name for the electric chiller condenser side outlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates a condenser side outlet air node.

#### 1.22.9.9 Field: Minimum Part Load Ratio

This numeric field contains the electric chiller's minimum part load ratio. The expected range is between 0 and 1. The minimum part load is not the load where the machine shuts off, but where the amount of power remains constant to produce smaller loads than this fraction.

#### 1.22.9.10 Field: Maximum Part Load Ratio

This numeric field contains the electric chiller's maximum part load ratio. This value may exceed 1, but the normal range is between 0 and 1.1.

#### 1.22.9.11 Field: Optimum Part Load Ratio

This numeric field contains the electric chiller's optimum part load ratio. This is the part load ratio at which the chiller performs at its maximum COP.

#### 1.22.9.12 Field: Design Condenser Inlet Temperature

This numeric field contains the electric chiller's condenser inlet design temperature in Celsius.

#### 1.22.9.13 Field: Temperature Rise Coefficient

This numeric field contains the electric chiller's temperature rise coefficient which is defined as the ratio of the required change in condenser water temperature to a given change in chilled water temperature, which maintains the capacity at the nominal value. This is calculated as the following ratio:

$$\frac{TCEnt_{required} - TCEnt_{rated}}{TELV_{required} - TELV_{rated}} \quad (40)$$

where:

$TCEnt_{required}$  = Required entering condenser air or water temperature to maintain rated capacity.

$TCEnt_{rated}$  = Rated entering condenser air or water temperature at rated capacity.

$TELV_{required}$  = Required leaving evaporator water outlet temperature to maintain rated capacity.

$TELV_{rated}$  = Rated leaving evaporator water outlet temperature at rated capacity.

#### 1.22.9.14 Field: Design Chilled Water Outlet Temperature

This numeric field contains the electric chiller's evaporator outlet design temperature in Celsius.

#### 1.22.9.15 Field: Design Chilled Water Flow Rate

For variable volume chiller this is the maximum flow and for constant flow chiller this is the design flow rate. The units are in cubic meters per second.

#### 1.22.9.16 Field: Design Condenser Fluid Flow Rate

This numeric field contains the electric chiller's design condenser water flow rate in cubic meters per second. This field is autosizable. This field is also used to enter the air flow rate if the Condenser Type = AirCooled or EvaporativelyCooled and Heat Recovery is specified.

#### 1.22.9.17 Capacity Ratio Curve

The Capacity Ratio Curve is a quadratic equation that determines the Ratio of Available Capacity to Nominal Capacity. The defining equation is:

$$AvailToNominalCapacityRatio = C_1 + C_2 \Delta_{temp} + C_3 \Delta_{temp}^2 \quad (41)$$

Where the Delta Temperature is defined as:

$$\Delta_{Temp} = \frac{TempCondIn - TempCondInDesign}{TempRiseCoefficient} - (TempEvapOut - TempEvapOutDesign) \quad (42)$$

TempCondIn = Temperature entering the condenser (water or air temperature depending on condenser type).

TempCondInDesign = Design Condenser Inlet Temperature from User input above.

TempEvapOut = Temperature leaving the evaporator.

TempEvapOutDesign = Design Chilled Water Outlet Temperature from User input above.

TempRiseCoefficient = User Input from above.

The following three fields contain the coefficients for the quadratic equation.

**1.22.9.18 Field: Coefficient 1 of Capacity Ratio Curve**

This numeric field contains the first coefficient for the capacity ratio curve.

**1.22.9.19 Field: Coefficient 2 of Capacity Ratio Curve**

This numeric field contains the second coefficient for the capacity ratio curve.

**1.22.9.20 Field: Coefficient 3 of Capacity Ratio Curve**

This numeric field contains the third coefficient for the capacity ratio curve.

**1.22.9.21 Power Ratio Curve**

The Power Ratio Curve is a quadratic equation that determines the Ratio of Full Load Power at Available Capacity to Full Load Power at Nominal Capacity. The defining equation is:

$FullLoadPowerRatio = C_1 + C_2 AvailToNominalCapRatio + C_3 AvailToNominalCapRatio^2$  The following three fields contain the coefficients for the quadratic equation.

**1.22.9.22 Field: Coefficient 1 of the power ratio curve**

This numeric field contains the first coefficient for the power ratio curve.

**1.22.9.23 Field: Coefficient 2 of Power Ratio Curve**

This numeric field contains the second coefficient for the power ratio curve.

**1.22.9.24 Field: Coefficient 3 of Power Ratio Curve**

This numeric field contains the third coefficient for the power ratio curve.

**1.22.9.25 Full Load Ratio Curve**

The Full Load Ratio Curve is a quadratic equation that determines the fraction of full load power. The defining equation is:

$$FracFullLoadPower = C_1 + C_2 PartLoadRatio + C_3 PartLoadRatio^2 \quad (43)$$

The following three fields contain the coefficients for the quadratic equation.

**1.22.9.26 Field: Coefficient 1 of Full Load Ratio Curve**

This numeric field contains the first coefficient for the full load ratio curve.

**1.22.9.27 Field: Coefficient 2 of Full Load Ratio Curve**

This numeric field contains the second coefficient for the full load ratio curve.

**1.22.9.28 Field: Coefficient 3 of Full Load Ratio Curve**

This numeric field contains the third coefficient for the full load ratio curve.

**1.22.9.29 Field: Chilled Water Outlet Temperature Lower Limit**

This numeric field contains the lower limit for the evaporator outlet temperature. This temperature acts as a cut off for heat transfer in the evaporator, so that the fluid doesn't get too cold.

**1.22.9.30 Field: Chiller Flow Mode**

This choice field determines how the chiller operates with respect to the intended fluid flow through the device's evaporator. There are three different choices for specifying operating modes for the intended flow behavior: "NotModulated," "ConstantFlow," and "LeavingSetpointModulated." NotModulated is useful for either variable or constant speed pumping arrangements where the chiller is passive in the sense that although it makes a nominal request for its design flow rate it can operate at varying flow rates. ConstantFlow is useful for constant speed pumping arrangements where the chiller's request for flow is stricter and can increase the overall loop flow. LeavingSetpointModulated changes the chiller model to internally vary the flow rate so that the temperature leaving the chiller matches a setpoint. In all cases the operation of the external plant system can also impact the flow through the chiller -- for example if the relative sizes and operation are such that flow is restricted and the requests cannot be met. The default, if not specified, is NotModulated.

#### **1.22.9.31 Field: Design Heat Recovery Water Flow Rate**

This is the design flow rate used if the heat recovery option is being simulated. If this value is greater than 0.0 then a heat recovery loop must be specified and attached to the chiller using the next 2 node fields. To determine how the heat recovery algorithm works look at the Engineering Manual at the Chiller:Electric with Heat Recovery section. The units are in cubic meters per second. This field is autosizable. When autosizing, the flow rate is simply the product of the design condenser flow rate and the condenser heat recovery relative capacity fraction set in the field below.

#### **1.22.9.32 Field: Heat Recovery Inlet Node Name**

This alpha field contains the identifying name for the electric chiller heat recovery side inlet node. A heat recovery loop must be specified.

#### **1.22.9.33 Field: Heat Recovery Outlet Node Name**

This alpha field contains the identifying name for the electric chiller heat recovery side outlet node. A heat recovery loop must be specified.

#### **1.22.9.34 Field: Sizing Factor**

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Capacity, Design Chilled Water Flow Rate and Design Condenser Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

#### **1.22.9.35 Field: Basin Heater Capacity**

This numeric field contains the capacity of the chiller's electric basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the chiller is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

#### **1.22.9.36 Field: Basin Heater Setpoint Temperature**

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the chiller is off. This set point temperature must be greater than or equal to 2°C, and the default value is 2°C if this field is left blank.

#### **1.22.9.37 Field: Basin Heater Operating Schedule Name**

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the chiller is off.

#### **1.22.9.38 Field: Condenser Heat Recovery Relative Capacity Fraction**

This field is optional. It can be used to describe the physical size of the heat recovery portion of a split bundle condenser section. This fraction describes the relative capacity of the heat recovery bundle of a split condenser compared to the nominal, full load heat rejection rate of the chiller. This fraction will be applied to the full heat rejection when operating at nominal capacity and nominal COP to model a capacity limit for the heat rejection. If this field is not entered then the capacity fraction is set to 1.0.

#### **1.22.9.39 Field: Heat Recovery Inlet High Temperature Limit Schedule Name**

This field is optional. It can be used to control heat recovery operation of the chiller. The schedule named here should contain temperature values, in C, that describe an upper limit for the return fluid temperatures entering the chiller at the heat recovery inlet node. If the fluid temperature is too high, then the heat recovery will not operate. This is useful to restrict the chiller lift from becoming too high and to avoid overheating the hot water loop. This limit can be used with or without the alternate control using leaving setpoint that is set in the next field.

#### **1.22.9.40 Field: Heat Recovery Leaving Temperature Setpoint Node Name**

This field is optional. It can be used to refine the model and controls for heat recovery operation of the chiller. The node named here should have a setpoint placed on it by a setpoint manager. If the plant loop's demand calculation scheme is set to SingleSetpoint, then a single setpoint manager should be used. If the plant loop's demand calculation is set to DualSetpointDeadband then a dual setpoint manager should be used and the upper setpoint is used for control. When this field is used, a different model is used for determining the distribution of rejected heat between the two bundles that is more appropriate for series bundle arrangements and for chiller's that are able to produce relatively higher temperature heated fluids.

An example of this statement in an IDF is:

```

- HVAC,Average,Chiller Heat Recovery Outlet Temperature [C]
- HVAC,Average,Chiller Heat Recovery Mass Flow Rate [kg/s]
- HVAC,Average,Chiller Effective Heat Rejection Temperature [C]

These chiller output variables are defined above under "Generic Chiller Outputs."

### 1.22.11 Chiller:Electric:EIR

This chiller model is the empirical model used in the DOE-2.1 building energy simulation program. The model uses performance information at reference conditions along with three curve fits for cooling capacity and efficiency to determine chiller operation at off-reference conditions. Chiller performance curves can be generated by fitting manufacturer's catalog data or measured data. Performance curves for more than 160 chillers, including the default DOE-2.1E reciprocating and centrifugal chillers, are provided in the EnergyPlus Reference DataSets (Chillers.idf and AllDataSets.idf).

Note: Chiller:Electric:EIR objects and their associated performance curve objects are developed using performance information for a specific chiller and should normally be used together for an EnergyPlus simulation. Changing the object input values, or swapping performance curves between chillers, should be done with caution.

#### 1.22.11.1 Field: Name

This alpha field contains the identifying name for the electric EIR chiller.

#### 1.22.11.2 Field: Reference Capacity

This numeric field contains the reference cooling capacity of the chiller in Watts. This should be the capacity of the chiller at the reference temperatures and

water flow rates defined below. Alternately, this field can be autosized.

#### **1.22.11.3 Field: Reference COP**

This numeric field contains the chiller's coefficient of performance. This value should **not** include energy use due to pumps or cooling tower fans. This COP should be at the reference temperatures and water flow rates defined below. This value **should** include evap-cooled or air-cooled condenser fans except when the Condenser Fan Power Ratio input field defined below is used and that input value is greater than 0. For the case when condenser fan power is modeled separately, the calculated condenser fan energy is reported on the same electric meter as compressor power. Be careful to not duplicate this energy use.

#### **1.22.11.4 Field: Reference Leaving Chilled Water Temperature**

This numeric field contains the chiller's reference leaving chilled water temperature in Celsius. The default value is 6.67°C.

#### **1.22.11.5 Field: Reference Entering Condenser Fluid Temperature**

This numeric field contains the chiller's reference entering condenser fluid temperature in Celsius. The default value is 29.4°C. For water-cooled chillers this is the water temperature entering the condenser (e.g., leaving the cooling tower). For air- or evap-cooled condensers this is the entering outdoor air dry-bulb or wet-bulb temperature, respectively.

#### **1.22.11.6 Field: Reference Chilled Water Flow Rate**

For a variable flow chiller this is the maximum water flow rate and for a constant flow chiller this is the operating water flow rate through the chiller's evaporator. The units are in cubic meters per second. The minimum value for this numeric input field must be greater than zero, or this field can be autosized.

#### **1.22.11.7 Field: Reference Condenser Fluid Flow Rate**

This numeric field contains the chiller's operating condenser water flow rate in cubic meters per second. This field can be autosized. This field is also used to enter the air flow rate if Condenser Type = AirCooled or EvaporativelyCooled and Heat Recovery is specified..

#### **1.22.11.8 Field: Cooling Capacity Function of Temperature Curve Name**

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the cooling capacity as a function of the leaving chilled water temperature and the entering condenser fluid temperature. The output of this curve is multiplied by the reference capacity to give the cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the reference temperatures). The curve should have a value of 1.0 at the reference temperatures and flow rates specified above. The biquadratic curve should be valid for the range of water temperatures anticipated for the simulation.

#### **1.22.11.9 Field: Electric Input to Cooling Output Ratio Function of Temperature Curve Name**

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input to cooling output ratio (EIR) as a function of the leaving chilled water temperature and the entering condenser fluid temperature. The EIR is the inverse of the COP. The output of this curve is multiplied by the reference EIR (inverse of the reference COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the reference temperatures). The curve should have a value of 1.0 at the reference temperatures and flow rates specified above. The biquadratic curve should be valid for the range of water temperatures anticipated for the simulation.

#### **1.22.11.10 Field: Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve Name**

The name of a quadratic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the part-load ratio (EIRfPLR). The EIR is the inverse of the COP, and the part-load ratio is the actual cooling load divided by the chiller's available cooling capacity. This curve is generated by dividing the operating electric input power by the available full-load capacity (do not divide by load) at the specific operating temperatures. The curve output should decrease from 1 towards 0 as part-load ratio decreases from 1 to 0. The output of this curve is multiplied by the reference full-load EIR (inverse of the reference COP) and the Energy Input to Cooling Output Ratio Function of Temperature Curve to give the EIR at the specific temperatures and part-load ratio at which the chiller is operating. This curve should have a value of 1.0 when the part-load ratio equals 1.0. An ideal chiller with the same efficiency at all part-load ratio's would use a performance curve that has a value of 0 when the part-load ratio equals 0 (i.e., a line connecting 0,0 and 1,1 when plotted as EIRfPLR versus PLR), however, actual systems can have part-load EIR's slightly above or below this line (i.e., part-load efficiency often differs from rated efficiency). The quadratic curve should be valid for the range of part-load ratios anticipated for the simulation.

#### **1.22.11.11 Field: Minimum Part Load Ratio**

This numeric field contains the chiller's minimum part-load ratio. The expected range is between 0 and 1. Below this part-load ratio, the compressor cycles on and off to meet the cooling load. The Minimum Part Load Ratio must be less than or equal to the Maximum Part Load Ratio. The default value is 0.1.

#### **1.22.11.12 Field: Maximum Part Load Ratio**

This numeric field contains the chiller's maximum part-load ratio. This value may exceed 1, but the normal range is between 0 and 1.0. The Maximum Part Load Ratio must be greater than or equal to the Minimum Part Load Ratio. The default value is 1.0.

#### **1.22.11.13 Field: Optimum Part Load Ratio**

This numeric field contains the chiller's optimum part-load ratio. This is the part-load ratio at which the chiller performs at its maximum COP. The optimum part-load ratio must be greater than or equal to the Minimum Part Load Ratio, and less than or equal to the Maximum Part Load Ratio. The default value is 1.0.

#### **1.22.11.14 Field: Minimum Unloading Ratio**

This numeric field contains the chiller's minimum unloading ratio. The expected range is between 0 and 1. The minimum unloading ratio is where the chiller capacity can no longer be reduced by unloading and must be false loaded to meet smaller cooling loads. A typical false loading strategy is hot-gas bypass. The minimum unloading ratio must be greater than or equal to the Minimum Part Load Ratio, and less than or equal to the Maximum Part Load Ratio. The default value is 0.2.

#### **1.22.11.15 Field: Chilled Water Inlet Node Name**

This required alpha field contains the identifying name for the chiller plant side (chilled water) inlet node.

#### **1.22.11.16 Field: Chilled Water Outlet Node Name**

This required alpha field contains the identifying name for the chiller plant side (chilled water) outlet node.

#### **1.22.11.17 Field: Condenser Inlet Node Name**

This alpha field contains the identifying name for the chiller condenser side inlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and a condenser inlet node name is specified here, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates an outdoor air node and the air temperature information on this node is taken directly from the weather file (no node height adjustment).

#### **1.22.11.18 Field: Condenser Outlet Node Name**

This alpha field contains the identifying name for the chiller condenser side outlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates a condenser side outlet air node.

#### **1.22.11.19 Field: Condenser Type**

This alpha field determines what type of condenser will be modeled with this chiller. Valid condenser types are AirCooled, WaterCooled, and EvaporativelyCooled with the default being WaterCooled if not specified. AirCooled and EvaporativelyCooled do not require a Condenser Loop to be specified, whereas the WaterCooled option requires the full specification of the Condenser Loop and its associated equipment.

#### **1.22.11.20 Field: Condenser Fan Power Ratio**

This field is used to model condenser fan power associated with air-cooled or evaporatively-cooled condensers (for cooling towers, refer to Group - Condenser Equipment). Enter the ratio of the condenser fan power to the reference chiller cooling capacity in W/W. If this input is greater than 0, the condenser fan power is modeled separately from compressor power. In addition, if condenser fan power is modeled using this input, the reference COP and "Electric Input to Cooling Output Ratio Function of " performance curves should not include condenser fan power.

#### **1.22.11.21 Field: Fraction of Compressor Electric Power Rejected by Condenser**

This numeric input represents the fraction of compressor electrical energy consumption that must be rejected by the condenser. Enter a value of 1.0 when modeling hermetic chillers. For open chillers, enter the compressor motor efficiency. This value must be greater than 0.0 and less than or equal to 1.0, with a default value of 1.0.

#### **1.22.11.22 Field: Leaving Chilled Water Lower Temperature Limit**

This numeric field contains the lower limit for the leaving chilled water temperature in Celsius. This temperature acts as a cut off for heat transfer in the evaporator, so that the fluid doesn't get too cold. This input field is currently unused. The default value is 2°C.

#### **1.22.11.23 Field: Chiller Flow Mode**

This choice field determines how the chiller operates with respect to the intended fluid flow through the device's evaporator. There are three different choices for specifying operating modes for the intended flow behavior: "NotModulated," "ConstantFlow," and "LeavingSetpointModulated." NotModulated is useful for either variable or constant speed pumping arrangements where the chiller is passive in the sense that although it makes a nominal request for its design flow rate it can operate at varying flow rates. ConstantFlow is useful for constant speed pumping arrangements where the chiller's request for flow is stricter and can increase the overall loop flow. LeavingSetpointModulated changes the chiller model to internally vary the flow rate so that the temperature leaving the chiller matches a

setpoint. In all cases the operation of the external plant system can also impact the flow through the chiller -- for example if the relative sizes and operation are such that flow is restricted and the requests cannot be met. The default, if not specified, is NotModulated.

#### **1.22.11.24 Field: Design Heat Recovery Water Flow Rate**

This is the design heat recovery water flow rate if the heat recovery option is being simulated. If this value is greater than 0.0 (or Autosize), a heat recovery loop must be specified and attached to the chiller using the next two node fields. The units are in cubic meters per second. This field is autosizable. When autosizing, the flow rate is simply the product of the design condenser flow rate and the condenser heat recovery relative capacity fraction set in the field below.

#### **1.22.11.25 Field: Heat Recovery Inlet Node Name**

This alpha field contains the identifying name for the chiller heat recovery side inlet node. If the user wants to model chiller heat recovery, a heat recovery loop must be specified.

#### **1.22.11.26 Field: Heat Recovery Outlet Node Name**

This alpha field contains the identifying name for the chiller heat recovery side outlet node. If the user wants to model chiller heat recovery, a heat recovery loop must be specified.

#### **1.22.11.27 Field: Sizing Factor**

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Reference Capacity, Reference Chilled Water Flow Rate and Reference Condenser Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

#### **1.22.11.28 Field: Basin Heater Capacity**

This numeric field contains the capacity of the chiller's electric basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the chiller is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

#### **1.22.11.29 Field: Basin Heater Setpoint Temperature**

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the chiller is off. This set point temperature must be greater than or equal to 2°C, and the default value is 2°C if this field is left blank.

#### **1.22.11.30 Field: Basin Heater Operating Schedule Name**

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the chiller is off.

#### **1.22.11.31 Field: Condenser Heat Recovery Relative Capacity Fraction**

This field is optional. It can be used to describe the physical size of the heat recovery portion of a split bundle condenser section. This fraction describes the relative capacity of the heat recovery bundle of a split condenser compared to the nominal, full load heat rejection rate of the chiller. This fraction will be applied to the full heat rejection when operating at nominal capacity and nominal COP to model a capacity limit for the heat rejection. If this field is not entered then the capacity fraction is set to 1.0.

#### **1.22.11.32 Field: Heat Recovery Inlet High Temperature Limit Schedule Name**

This field is optional. It can be used to control heat recovery operation of the chiller. The schedule named here should contain temperature values, in C, that describe an upper limit for the return fluid temperatures entering the chiller at the heat recovery inlet node. If the fluid temperature is too high, then the heat recovery will not operate. This is useful to restrict the chiller lift from becoming too high and to avoid overheating the hot water loop. This limit can be used with or without the alternate control using leaving setpoint that is set in the next field.

#### **1.22.11.33 Field: Heat Recovery Leaving Temperature Setpoint Node Name**

This field is optional. It can be used to refine the model and controls for heat recovery operation of the chiller. The node named here should have a setpoint placed on it by a setpoint manager. If the plant loop's demand calculation scheme is set to SingleSetpoint, then a single setpoint manager should be used. If the plant loop's demand calculation is set to DualSetpointDeadband then a dual setpoint manager should be used and the upper setpoint is used for control. When

this field is used, a different model is used for determining the distribution of rejected heat between the two bundles that is more appropriate for series bundle arrangements and for chiller's that are able to produce relatively higher temperature heated fluids.

An example of this statement in an IDF is:

- HVAC,Average,Chiller Heat Recovery Outlet Temperature [C]
- HVAC,Average,Chiller Heat Recovery Mass Flow Rate [kg/s]
- HVAC,Average,Chiller Effective Heat Rejection Temperature [C]

Most of these chiller output variables are defined above under "Generic Chiller Outputs." Output variables not described above are discussed here.

#### **1.22.12.1 Chiller Condenser Fan Electric Power [W]**

#### **1.22.12.2 Chiller Condenser Fan Electric Energy [J]**

These outputs are for the electric power consumption of the chiller condenser fan and are applicable to air- or evaporatively-cooled chillers. These reports are available only for the Chiller:Electric:EIR and only when the Condenser Fan Power Ratio input field is greater than 0. This output is also added to a meter object with Resource Type = Electricity, End Use Key = Chillers, Group Key = Plant (Ref. Output: Meter objects).

#### **1.22.12.3 Chiller Capacity Temperature Modifier Multiplier []**

This is the output of the curve object Cooling Capacity Function of Temperature Curve.

#### **1.22.12.4 Chiller EIR Temperature Modifier Multiplier []**

This is the output of the curve object Electric Input to Cooling Output Ratio Function of Temperature Curve.

#### **1.22.12.5 Chiller EIR Part Load Modifier Multiplier []**

This is the output of the curve object Electric Input to Cooling Output Ratio Function of Part Load Curve.

#### **1.22.12.6 Chiller Part Load Ratio []**

This output is the ratio of the evaporator heat transfer rate plus the false load heat transfer rate (if applicable) to the available chiller capacity. This value is used to determine Chiller EIR Part Load Modifier Multiplier.

#### **1.22.12.7 Chiller Cycling Ratio []**

The cycling ratio is the amount of time the chiller operates during each simulation timestep. If the chiller part-load ratio falls below the minimum part-load ratio, the chiller cycles on and off to meet the cooling load.

#### **1.22.12.8 Chiller False Load Heat Transfer Rate [W]**

#### **1.22.12.9 Chiller False Load Heat Transfer Energy [J]**

These outputs are the heat transfer rate and total heat transfer due to false loading of the chiller. When the chiller part-load ratio is below the minimum unloading ratio, the chiller false loads (e.g. hot-gas bypass) to further reduce capacity. The false load heat transfer output variable is not metered.

### **1.22.13 Chiller:Electric:ReformulatedEIR**

This chiller model, developed through the CoolTools™ project sponsored by Pacific Gas and Electric Company (PG&E), is an empirical model similar to EnergyPlus' Chiller:Electric:EIR model. The model uses performance information at reference conditions along with three curve fits for cooling capacity and efficiency to determine chiller operation at off-reference conditions. The model has the same capabilities as the Chiller:Electric:EIR model, but can potentially provide significant accuracy improvement over the Chiller:Electric:EIR model for variable-speed compressor drive and variable condenser water flow applications. Chiller performance curves can be generated by fitting manufacturer's catalog data or measured data. Performance curves developed from manufacturer's performance data are provided in the EnergyPlus Reference DataSets (Chillers.idf and AllDataSets.idf). This chiller model can be used to predict the performance of various chiller types (e.g., reciprocating, screw, scroll, and centrifugal) with water-cooled condensers.

The main difference between this model and the Chiller:Electric:EIR model is the condenser fluid temperature used in the associated performance curves: the Chiller:Electric:ReformulatedEIR model uses the LEAVING condenser water temperature while the Chiller:Electric:EIR model uses the ENTERING condenser water temperature.

Note: Chiller:Electric:Reformulated EIR objects and their associated performance curve objects are developed using performance information for a specific chiller and should almost always be used together for an EnergyPlus simulation. Changing the object input values, or swapping performance curves between chillers, should be done with extreme caution. For example, if the user wishes to model a chiller size that is different from the reference capacity, it is highly recommended that the reference flow rates be scaled proportionately to the change in reference capacity. Although this model can provide more accurate prediction than the Chiller:Electric:EIR model, it requires more performance data to develop the associated performance curves (at least 12 points from full-load performance and 7 points from part-load performance).

#### **1.22.13.1 Field: Chiller Name**

This alpha field contains the identifying name for this chiller.

#### **1.22.13.2 Field: Reference Capacity**

This numeric field contains the reference cooling capacity of the chiller in Watts. This should be the capacity of the chiller at the reference temperatures and water flow rates defined below. Alternately, this field can be autosized.

#### **1.22.13.3 Field: Reference COP**

This numeric field contains the chiller's coefficient of performance. This value should **not** include energy use due to pumps or cooling tower fans. This COP should be at the reference temperatures and water flow rates defined below.

#### **1.22.13.4 Field: Reference Leaving Chilled Water Temperature**

This numeric field contains the chiller's reference leaving chilled water temperature in Celsius. The default value is 6.67°C.

#### **1.22.13.5 Field: Reference Leaving Condenser Water Temperature**

This numeric field contains the chiller's reference leaving condenser water temperature in Celsius. The default value is 35°C.

#### **1.22.13.6 Field: Reference Chilled Water Flow Rate**

For a variable flow chiller this is the maximum water flow rate and for a constant flow chiller this is the operating water flow rate through the chiller's evaporator. The units are in cubic meters per second. The minimum value for this numeric input field must be greater than zero, or this field can be autosized.

#### **1.22.13.7 Field: Reference Condenser Water Flow Rate**

This numeric field contains the chiller's operating condenser water flow rate in cubic meters per second. The units are in cubic meters per second. The minimum value for this numeric input field must be greater than zero, or this field can be autosized.

#### **1.22.13.8 Field: Cooling Capacity Function of Temperature Curve Name**

The name of a biquadratic performance curve (ref: Performance Curves) that parameterizes the variation of the cooling capacity as a function of the leaving chilled water temperature and the leaving condenser water temperature. The output of this curve is multiplied by the reference capacity to give the cooling capacity at specific temperature operating conditions (i.e., at temperatures different from the reference temperatures). The curve should have a value of 1.0 at the reference temperatures and flow rates specified above. The biquadratic curve should be valid for the range of water temperatures anticipated for the simulation (otherwise the program issues warning messages).

#### **1.22.13.9 Field: Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve Type**

This choice field determines which type of the Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve is used in the chiller modeling. Two curve types are available: (1) Type LeavingCondenserWaterTemperature is based on the leaving condenser water temperature. (2) Type Lift is based on the normalized lift, which is the temperature difference between the leaving condenser water temperature and the leaving evaporator water temperature.

#### **1.22.13.10 Field: Electric Input to Cooling Output Ratio Function of Temperature Curve Name**

The name of the Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve. The form of this curve is based on the input for Electric Input to Cooling Output RatioFunction of Part Load Ratio Curve Type. For the type of LeavingCondenserWaterTemperature, the curve object type should be Curve:Bicubic or Table:TwoIndependentVariables that parameterizes the variation of the energy input to cooling output ratio (EIR) as a function of the leaving chilled water temperature and the leaving condenser water temperature. For the type of Lift, the curve object type should be Curve:ChillerPartLoadWithLiftCurves or Table:MultiVariableLookup that parameterizes the variation of EIR as a function of the normalized fractional Lift, normalized Tdev and the PLR. Tdev is the difference between Leaving Chilled Water Temperature and Reference Chilled Water Temperature. Lift is the Leaving Condenser Water Temperature and Leaving Chilled Water Temperature. The EIR is the inverse of the COP. The output of this curve is multiplied by the reference EIR (inverse of the reference COP) to give the EIR at specific temperature operating conditions (i.e., at temperatures different from the reference temperatures). The curve should have a value of 1.0 at the reference temperatures and flow rates specified above. The biquadratic curve should be valid for the range of water temperatures anticipated for the simulation (otherwise the program issues warning messages).

#### **1.22.13.11 Field: Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve Name**

The name of a bicubic performance curve (ref: Performance Curves) that parameterizes the variation of the energy input ratio (EIR) as a function of the leaving condenser water temperature and the part-load ratio (EIRfTPLR). The EIR is the inverse of the COP, and the part-load ratio is the actual cooling load divided by the chiller's available cooling capacity. This curve is generated by dividing the operating electric input power by the available full-load capacity (do not divide by load) at the specific operating temperatures. The curve output should decrease from 1 towards 0 as part-load ratio decreases from 1 to 0. The output of this curve is multiplied by the reference full-load EIR (inverse of the reference COP) and the Energy Input to Cooling Output Ratio Function of Temperature Curve to give the EIR at the specific temperatures and part-load ratio at which the chiller is operating. This curve should have a value of 1.0 at the reference leaving condenser water temperature with the part-load ratio equal to 1.0. An ideal chiller with the same efficiency at all part-load ratios would use a performance curve that has a value of 0 when the part-load ratio equals 0 (i.e., a line connecting 0,0 and 1,1 when plotted as EIRfTPLR versus PLR), however, actual systems can have part-load EIR's slightly above or below this line (i.e., part-load efficiency often differs from rated efficiency). The bicubic curve should be valid for the range of condenser water temperatures and part-load ratios anticipated for the simulation (otherwise the program issues warning messages).

Note: Although a bicubic curve requires 10 coefficients (ref. Curve:Bicubic), coefficients 7, 9 and 10 are typically not used in the performance curve described here and should be entered as 0 unless sufficient performance data and regression accuracy exist to justify the use of these coefficients. Additionally, coefficients 2, 3, and 6 should not be used unless sufficient temperature data is available to accurately define the performance curve (i.e., negative values may result from insufficient data).

#### **1.22.13.12 Field: Minimum Part Load Ratio**

This numeric field contains the chiller's minimum part-load ratio. The expected range is between 0 and 1. Below this part-load ratio, the compressor cycles on and off to meet the cooling load. The Minimum Part Load Ratio must be less than or equal to the Maximum Part Load Ratio. The default value is 0.1.

#### **1.22.13.13 Field: Maximum Part Load Ratio**

This numeric field contains the chiller's maximum part-load ratio. This value may exceed 1, but the normal range is between 0 and 1.0. The Maximum Part Load Ratio must be greater than or equal to the Minimum Part Load Ratio. The default value is 1.0.

#### **1.22.13.14 Field: Optimum Part Load Ratio**

This numeric field contains the chiller's optimum part-load ratio. This is the part-load ratio at which the chiller performs at its maximum COP. The optimum part-load ratio must be greater than or equal to the Minimum Part Load Ratio, and less than or equal to the Maximum Part Load Ratio. The default value is 1.0.

#### **1.22.13.15 Field: Minimum Unloading Ratio**

This numeric field contains the chiller's minimum unloading ratio. The expected range is between 0 and 1. The minimum unloading ratio is where the chiller capacity can no longer be reduced by unloading and must be false loaded to meet smaller cooling loads. A typical false loading strategy is hot-gas bypass. The minimum unloading ratio must be greater than or equal to the Minimum Part Load Ratio, and less than or equal to the Maximum Part Load Ratio. The default value is 0.2.

#### **1.22.13.16 Field: Chilled Water Side Inlet Node**

This required alpha field contains the identifying name for the chiller plant side (chilled water) inlet node.

#### **1.22.13.17 Field: Chilled Water Side Outlet Node**

This required alpha field contains the identifying name for the chiller plant side (chilled water) outlet node.

#### **1.22.13.18 Field: Condenser Side Inlet Node**

This required alpha field contains the identifying name for the chiller condenser side inlet node.

#### **1.22.13.19 Field: Condenser Side Outlet Node**

This required alpha field contains the identifying name for the chiller condenser side outlet node.

#### **1.22.13.20 Field: Fraction of Compressor Electric Power Rejected by Condenser**

This numeric input represents the fraction of compressor electrical energy consumption that must be rejected by the condenser. Enter a value of 1.0 when modeling hermetic chillers. For open chillers, enter the compressor motor efficiency. This value must be greater than 0.0 and less than or equal to 1.0, with a default value of 1.0.

#### **1.22.13.21 Field: Leaving Chilled Water Lower Temperature Limit**

This numeric field contains the lower limit for the leaving chilled water temperature in Celsius. This temperature acts as a cut off for heat transfer in the evaporator, so that the water doesn't get too cold. This input field is currently unused. The default value is 2°C.

### 1.22.13.22 Field: Chiller Flow Mode Type

This choice field determines how the chiller operates with respect to the intended fluid flow through the device's evaporator. There are three different choices for specifying operating modes for the intended flow behavior: "NotModulated," "ConstantFlow," and "LeavingSetpointModulated." NotModulated is useful for either variable or constant speed pumping arrangements where the chiller is passive in the sense that although it makes a nominal request for its design flow rate it can operate at varying flow rates. ConstantFlow is useful for constant speed pumping arrangements where the chiller's request for flow is stricter and can increase the overall loop flow. LeavingSetpointModulated changes the chiller model to internally vary the flow rate so that the temperature leaving the chiller matches a setpoint. In all cases the operation of the external plant system can also impact the flow through the chiller -- for example if the relative sizes and operation are such that flow is restricted and the requests cannot be met. The default, if not specified, is NotModulated.

### 1.22.13.23 Field: Design Heat Recovery Water Flow Rate

This is the design heat recovery water flow rate if the heat recovery option is being simulated. If this value is greater than 0.0 (or autosize), a heat recovery loop must be specified and attached to the chiller using the next two node fields. The units are in cubic meters per second. This field is autosizable. When autosizing, the flow rate is simply the product of the design condenser flow rate and the condenser heat recovery relative capacity fraction set in the field below.

### 1.22.13.24 Field: Heat Recovery Inlet Node Name

This alpha field contains the identifying name for the chiller heat recovery side inlet node. If the user wants to model chiller heat recovery, a heat recovery loop must be specified and it can only be used with a water-cooled condenser.

### 1.22.13.25 Field: Heat Recovery Outlet Node Name

This alpha field contains the identifying name for the chiller heat recovery side outlet node. If the user wants to model chiller heat recovery, a heat recovery loop must be specified and it can only be used with a water-cooled condenser.

### 1.22.13.26 Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Reference Capacity, Reference Chilled Water Flow Rate and Reference Condenser Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

### 1.22.13.27 Field: Condenser Heat Recovery Relative Capacity Fraction

This field is optional. It can be used to describe the physical size of the heat recovery portion of a split bundle condenser section. This fraction describes the relative capacity of the heat recovery bundle of a split condenser compared to the nominal, full load heat rejection rate of the chiller. This fraction will be applied to the full heat rejection when operating at nominal capacity and nominal COP to model a capacity limit for the heat rejection. If this field is not entered then the capacity fraction is set to 1.0.

### 1.22.13.28 Field: Heat Recovery Inlet High Temperature Limit Schedule Name

This field is optional. It can be used to control heat recovery operation of the chiller. The schedule named here should contain temperature values, in C, that describe an upper limit for the return fluid temperatures entering the chiller at the heat recovery inlet node. If the fluid temperature is too high, then the heat recovery will not operate. This is useful to restrict the chiller lift from becoming too high and to avoid overheating the hot water loop. This limit can be used with or without the alternate control using leaving setpoint that is set in the next field.

### 1.22.13.29 Field: Heat Recovery Leaving Temperature Setpoint Node Name

This field is optional. It can be used to refine the model and controls for heat recovery operation of the chiller. The node named here should have a setpoint placed on it by a setpoint manager. If the plant loop's demand calculation scheme is set to SingleSetpoint, then a single setpoint manager should be used. If the plant loop's demand calculation is set to DualSetpointDeadband then a dual setpoint manager should be used and the upper setpoint is used for control. When this field is used, a different model is used for determining the distribution of rejected heat between the two bundles that is more appropriate for series bundle arrangements and for chiller's that are able to produce relatively higher temperature heated fluids.

An example of this statement in an IDF is:

## 1.22.14 Electric Reformulated EIR Chiller Outputs

The output variables for Chiller:Electric:ReformulatedEIR are the same as the output variables for Chiller:Electric:EIR (ref. Electric EIR Chiller Outputs), except for the Chiller Condenser Fan Electric Power and Energy reports

## 1.22.15 Chiller:EngineDriven

### 1.22.15.1 Field: Name

This alpha field contains the identifying name for the engine driven chiller.

### 1.22.15.2 Field: Condenser Type

This alpha field determines what type of condenser will be modeled with this chiller. The 3 type of condensers are AirCooled, WaterCooled, and EvaporativelyCooled with the default being AirCooled if not specified. AirCooled and EvaporativelyCooled do not require a Condenser Loop to be specified, where the WaterCooled option requires the full specification of the Condenser Loop and its associated equipment.

#### 1.22.15.3 Field: Nominal Capacity

This numeric field contains the nominal cooling capability of the chiller in Watts.

#### 1.22.15.4 Field: Nominal COP

This numeric field contains the chiller's coefficient of performance (COP).

#### 1.22.15.5 Field: Chilled Water Inlet Node Name

This required alpha field contains the identifying name for the chiller plant side inlet node.

#### 1.22.15.6 Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the chiller plant side outlet node.

#### 1.22.15.7 Field: Condenser Inlet Node Name

This alpha field contains the identifying name for the chiller condenser side inlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and a condenser inlet node name is specified here, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates an outdoor air node and the air temperature information on this node is taken directly from the weather file (no node height adjustment).

#### 1.22.15.8 Field: Condenser Outlet Node Name

This alpha field contains the identifying name for the chiller condenser side outlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates a condenser side outlet air node.

#### 1.22.15.9 Field: Minimum Part Load Ratio

This numeric field contains the chiller's minimum part load ratio. The expected range is between 0 and 1. The minimum part load is not the load where the machine shuts off, but where the amount of power remains constant to produce smaller loads than this fraction.

#### 1.22.15.10 Field: Maximum Part Load Ratio

This numeric field contains the chiller's maximum part load ratio. This value may exceed 1, but the normal range is between 0 and 1.1.

#### 1.22.15.11 Field: Optimum Part Load Ratio

This numeric field contains the chiller's optimum part load ratio. This is the part load ratio at which the chiller performs at its maximum COP.

#### 1.22.15.12 Field: Design Condenser Inlet Temperature

This numeric field contains the chiller's condenser inlet design temperature in Celsius.

#### 1.22.15.13 Field: Temperature Rise Coefficient

This numeric field contains the electric chiller's temperature rise coefficient which is defined as the ratio of the required change in condenser water temperature to a given change in chilled water temperature, which maintains the capacity at the nominal value. This is calculated as the following ratio:

$$\frac{TCEnt_{required} - TCEnt_{rated}}{TELV_{required} - TELV_{rated}} \quad (44)$$

where:

$TCEnt_{required}$  = Required entering condenser air or water temperature to maintain rated capacity.

$TCEnt_{rated}$  = Rated entering condenser air or water temperature at rated capacity.

$TELV_{required}$  = Required leaving evaporator water outlet temperature to maintain rated capacity.

TEL<sub>V<sub>rated</sub></sub> = Rated leaving evaporator water outlet temperature at rated capacity.

#### 1.22.15.14 Field: Design Chilled Water Outlet Temperature

This numeric field contains the chiller's evaporator outlet design temperature in Celsius.

#### 1.22.15.15 Field: Design Chilled Water Flow Rate

For variable volume chiller this is the maximum flow and for constant flow chiller this is the design flow rate. The units are in cubic meters per second.

#### 1.22.15.16 Field: Design Condenser Water Flow Rate

This numeric field contains the chiller's design condenser water flow rate in cubic meters per second. This field can be autosized. This field is not user for Condenser Type = AirCooled or EvaporativelyCooled.

#### 1.22.15.17 Capacity Ratio Curve

The Capacity Ratio Curve is a quadratic equation that determines the Ratio of Available Capacity to Nominal Capacity. The defining equation is:

$$AvailToNominalCapacityRatio = C_1 + C_2 \Delta_{temp} + C_3 \Delta_{temp}^2 \quad (45)$$

Where the Delta Temperature is defined as:

$$FullLoadtoPowerRatio = C_1 + C_2 AvailToNominalCapRatio + C_3 AvailToNominalCapRatio^2 \quad (46)$$

TempCondIn = Temperature entering the condenser (water or air temperature depending on condenser type).

TempCondInDesign = Design Condenser Inlet Temperature from User input above.

TempEvapOut = Temperature leaving the evaporator.

TempEvapOutDesign = Design Chilled Water Outlet Temperature from User input above.

TempRiseCoefficient = User Input from above.

The following three fields contain the coefficients for the quadratic equation.

#### 1.22.15.18 Field: Coefficient 1 of Capacity Ratio Curve

This numeric field contains the first coefficient for the capacity ratio curve.

#### 1.22.15.19 Field: Coefficient 2 of Capacity Ratio Curve

This numeric field contains the second coefficient for the capacity ratio curve.

#### 1.22.15.20 Field: Coefficient 3 of Capacity Ratio Curve

This numeric field contains the third coefficient for the capacity ratio curve.

#### 1.22.15.21 Power Ratio Curve

The Power Ratio Curve is a quadratic equation that determines the Ratio of Full Load to Power. The defining equation is:

$FracFullLoadPower = C_1 + C_2 PartLoadRatio + C_3 PartLoadRatio^2$  The following three fields contain the coefficients for the quadratic equation.

#### 1.22.15.22 Field: Coefficient 1 of Power Ratio Curve

This numeric field contains the first coefficient for the power ratio curve.

#### 1.22.15.23 Field: Coefficient 2 of Power Ratio Curve

This numeric field contains the second coefficient for the power ratio curve.

#### 1.22.15.24 Field: Coefficient 3 of Power Ratio Curve

This numeric field contains the third coefficient for the power ratio curve.

#### 1.22.15.25 Full Load Ratio Curve

The Full Load Ratio Curve is a quadratic equation that determines the fraction of full load power. The defining equation is:

$$\text{CoolingLoadtoFuelCurve} = C_1 + C_2 * PLR + C_3 * PLR^2 \quad (47)$$

The following three fields contain the coefficients for the quadratic equation.

**1.22.15.26 Field: Coefficient 1 of Full Load Ratio Curve**

This numeric field contains the first coefficient for the full load ratio curve.

**1.22.15.27 Field: Coefficient 2 of Full Load Ratio Curve**

This numeric field contains the second coefficient for the full load ratio curve.

**1.22.15.28 Field: Coefficient 3 of Full Load Ratio Curve**

This numeric field contains the third coefficient for the full load ratio curve.

**1.22.15.29 Field Chilled Water Outlet Temperature Lower Limit**

This numeric field contains the lower limit for the evaporator outlet temperature. This temperature acts as a cut off for heat transfer in the evaporator, so that the fluid doesn't get too cold.

**1.22.15.30 Field: Fuel Use Curve Name**

This alpha field contains the name of the Cooling Load to Fuel Use curve. The curve itself is specified separately using the EnergyPlus Curve Manager. The Fuel Use Curve is a quadratic equation that determines the ratio of Cooling Load to Fuel Energy. The defining equation is:

$$\text{RecoveryJacketHeatToFuelRatio} = C_1 + C_2 RL + C_3 RL^2 \quad (48)$$

where PLR is the Part Load Ratio from the Chiller. The Part Load Based Fuel Input Curve determines the ratio of fuel energy per unit time (J/s) / cooling load (W). This is illustrated by the logic block in the Engine Driven Chiller algorithm.

```
IF (PartLoadRat == 0) THEN
  EngineDrivenFuelEnergy = 0
ELSE
  CIngLoadFuelRat = CurveValue(EngineDrivenChiller(ChillerNum)%CIngLoadtoFuelCurve, PartLoadRat )
  EngineDrivenFuelEnergy = QEvaporator / CIngLoadFuelRat
END IF
```

**1.22.15.31 Field: Jacket Heat Recovery Curve Name**

This alpha field contains the name of the Recovery Jacket Heat curve. The curve itself is specified separately using the EnergyPlus Curve Manager. The Recovery Jacket Heat Curve is a quadratic equation that determines the ratio of recovery jacket heat to fuel energy. The defining equation is:

$$\text{RecoveryLubeHeatToFuelRatio} = C_1 + C_2 RL + C_3 RL^2 \quad (49)$$

where RL is the Ratio of Load to Diesel Engine Capacity

**1.22.15.32 Field: Lube Heat Recovery Curve Name**

This alpha field contains the name of the Recovery Lube Heat curve. The curve itself is specified separately using the EnergyPlus Curve Manager. The Recovery Lubricant Heat Curve is a quadratic equation that determines the ratio of recovery lube heat to fuel energy. The defining equation is:

$$\text{TotalExhaustToFuelRatio} = C_1 + C_2 RL + C_3 RL^2 \quad (50)$$

where RL is the Ratio of Load to Diesel Engine Capacity

**1.22.15.33 Field: Total Exhaust Energy Curve Name**

This alpha field contains the name of the Total Exhaust Energy curve. The curve itself is specified separately using the EnergyPlus Curve Manager. The Total Exhaust Energy Curve is a quadratic equation that determines the ratio of total exhaust energy to fuel energy. The defining equation is:

$$\text{AbsoluteExhaustTemperature} = C_1 + C_2 RL + C_3 RL^2 \quad (51)$$

where RL is the Ratio of Load to Diesel Engine Capacity

**1.22.15.34 Field: Exhaust Temperature Curve Name**

This alpha field contains the name of the Exhaust Temperature curve. The curve itself is specified separately using the EnergyPlus Curve Manager. The Exhaust Temperature Curve is a quadratic equation that determines the absolute exhaust temperature. The defining equation is:

$$UAToCapacityRatio = C_1 \text{EngineCapacity}^{C_2} \quad (52)$$

where RL is the Ratio of Load to Diesel Engine Capacity

#### 1.22.15.35 U-Factor Times Area Curve

The U-Factor Times Area (UA) is an equation that determines the overall heat transfer coefficient for the exhaust gasses with the stack. The heat transfer coefficient ultimately helps determine the exhaust stack temperature. The defining equation is:

$$\frac{TCEnt_{required} - TCEnt_{rated}}{TELv_{required} - TELv_{rated}} \quad (53)$$

The following two fields contain the coefficients for the equation.

#### 1.22.15.36 Field: Coefficient 1 of U-Factor Times Area Curve

This numeric field contains the first coefficient for the overall heat transfer coefficient curve.

#### 1.22.15.37 Field: Coefficient 2 of U-Factor Times Area Curve

This numeric field contains the second (exponential) coefficient for the overall heat transfer coefficient curve.

#### 1.22.15.38 Field: Maximum Exhaust Flow per Unit of Power Output

This numeric field contains the maximum exhaust gas mass flow rate per watt of cooling provided by the engine driven chiller

#### 1.22.15.39 Field: Design Minimum Exhaust Temperature

This numeric field contains the steam saturation temperature in Celsius that would be used to determine the energy recovered from a water jacket heat exchanger on the engine.

#### 1.22.15.40 Field: Fuel Type

This alpha value specifies the type of fuel used in the engine. The fuel type can be NaturalGas, PropaneGas, Diesel, Gasoline, FuelOil#1, FuelOil#2, OtherFuel1 or OtherFuel2. This field is required.

#### 1.22.15.41 Field: Fuel Higher Heating Value

This numeric field contains the higher heating value of the fuel used in kJ/kg.

#### 1.22.15.42 Field: Design Heat Recovery Water Flow Rate

This numeric field specifies the heat recovery volumetric flow rate through the engine in m<sup>3</sup>/sec. The heat recovery loop manager and hot water tan must also be specified if heat energy is to be recovered from the engine driven chiller.

#### 1.22.15.43 Field: Heat Recovery Inlet Node Name

This alpha field contains the identifying name for the heat recovery side inlet. If a loop is connected, then the jacket and lubricant heat will be recovered. There is no need for an effectiveness term, since the jacket and lubricant recovered heat energies are the actual recovered energies.

#### 1.22.15.44 Field: Heat Recovery Outlet Node Name

This alpha field contains the identifying name for the heat recovery side outlet.

#### 1.22.15.45 Field: Chiller Flow Mode

This choice field determines how the chiller operates with respect to the intended fluid flow through the device's evaporator. There are three different choices for specifying operating modes for the intended flow behavior: "NotModulated," "ConstantFlow," and "LeavingSetpointModulated." NotModulated is useful for either variable or constant speed pumping arrangements where the chiller is passive in the sense that although it makes a nominal request for its design flow rate it can operate at varying flow rates. ConstantFlow is useful for constant speed pumping arrangements where the chiller's request for flow is stricter and can increase the overall loop flow. LeavingSetpointModulated changes the chiller model to internally vary the flow rate so that the temperature leaving the chiller matches a setpoint. In all cases the operation of the external plant system can also impact the flow through the chiller -- for example if the relative sizes and operation are such that flow is restricted and the requests cannot be met. The default, if not specified, is NotModulated.

#### 1.22.15.46 Field: Maximum Temperature for Heat Recovery at Heat Recovery Outlet Node

This field sets the maximum temperature that this piece of equipment can produce for heat recovery. The idea behind this field is that the current models do not take temperatures into account for availability and they just pass Q's around the loop without a temperature limit. This temperature limit puts an upper bound on the recovered heat and limits the max temperatures leaving the component.

As temperatures in the loop approach the maximum temperature, the temperature difference between the entering water and the surfaces in the piece of equipment becomes smaller. For the given heat recovery flow rate and that temperature difference the amount of heat recovered will be reduced, and eventually there will be no heat recovered when the entering water temperature is equal to the maximum temperature specified by the user in this field. The reduced amount of heat recovered will diminish if the temperature of the loop approach is the maximum temperature, and this will show up in the reporting. This allows the user to set the availability or the quality of the heat recovered for usage in other parts of the system or to heat domestic hot water supply. The temperature is specified in degrees C.

#### 1.22.15.47 Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Capacity, Design Chilled Water Flow Rate and Design Condenser Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

#### 1.22.15.48 Field: Basin Heater Capacity

This numeric field contains the capacity of the chiller's electric basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the chiller is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

#### 1.22.15.49 Field: Basin Heater Setpoint Temperature

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the chiller is off. This set point temperature must be greater than or equal to 2°C, and the default value is 2°C if this field is left blank.

#### 1.22.15.50 Field: Basin Heater Operating Schedule Name

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the chiller is off.

An example of this statement in an IDF is:

These chiller output variables are defined above under "Generic Chiller Outputs."

### 1.22.17 Chiller:CombustionTurbine

This chiller model is the empirical model from the Building Loads and System Thermodynamics (BLAST) program. Chiller performance curves are generated by fitting catalog data to third order polynomial equations. Three sets of coefficients are required.

#### 1.22.17.1 Field: Name

This alpha field contains the identifying name for the combustion turbine chiller.

#### 1.22.17.2 Field: Condenser Type

This alpha field determines what type of condenser will be modeled with this chiller. The 3 type of condensers are AirCooled, WaterCooled, and EvaporativelyCooled with the default being AirCooled if not specified. AirCooled and EvaporativelyCooled do not require a Condenser Loop to be specified, where the WaterCooled option requires the full specification of the Condenser Loop and its associated equipment.

#### 1.22.17.3 Field: Nominal Capacity

This numeric field contains the nominal cooling capability of the chiller in Watts.

#### 1.22.17.4 Field: Nominal COP

This numeric field contains the chiller's coefficient of performance (COP).

#### 1.22.17.5 Field: Chilled Water Inlet Node Name

This alpha field contains the identifying name for the combustion turbine chiller plant side inlet node.

**1.22.17.6 Field: Chilled Water Outlet Node Name**

This required alpha field contains the identifying name for the combustion turbine chiller plant side inlet node.

**1.22.17.7 Field: Chilled Water Outlet Node Name**

This required alpha field contains the identifying name for the combustion turbine chiller plant side outlet node.

**1.22.17.8 Field: Condenser Inlet Node Name**

This alpha field contains the identifying name for the combustion turbine chiller condenser side inlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and a condenser inlet node name is specified here, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air temperature is taken directly from the weather data. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates an outdoor air node and the air temperature information on this node is taken directly from the weather file (no node height adjustment).

**1.22.17.9 Field: Condenser Outlet Node Name**

This alpha field contains the identifying name for the combustion turbine chiller condenser side outlet node. This node name is required if the chiller is WaterCooled, and optional if the chiller is AirCooled or EvaporativelyCooled. If the chiller is AirCooled or EvaporativelyCooled and this field is left blank, the program automatically creates a condenser side outlet air node.

**1.22.17.10 Field: Minimum Part Load Ratio**

This numeric field contains the combustion turbine chiller's minimum part load ratio. The expected range is between 0 and 1. The minimum part load is not the load where the machine shuts off, but where the amount of power remains constant to produce smaller loads than this fraction.

**1.22.17.11 Field: Maximum Part Load Ratio**

This numeric field contains the combustion turbine chiller's maximum part load ratio. This value may exceed 1, but the normal range is between 0 and 1.1.

**1.22.17.12 Field: Optimum Part Load Ratio**

This numeric field contains the combustion turbine chiller's optimum part load ratio. This is the part load ratio at which the chiller performs at its maximum COP.

**1.22.17.13 Field: Design Condenser Inlet Temperature**

This numeric field contains the combustion turbine chiller's condenser inlet design temperature in Celsius.

**1.22.17.14 Field: Temperature Rise Coefficient**

This numeric field contains the electric chiller's temperature rise coefficient which is defined as the ratio of the required change in condenser water temperature to a given change in chilled water temperature, which maintains the capacity at the nominal value. This is calculated as the following ratio:

$$\frac{TCEnt_{required} - TCEnt_{rated}}{TELv_{required} - TELv_{rated}} \quad (54)$$

where:

$TCEnt_{required}$  = Required entering condenser air or water temperature to maintain rated capacity.

$TCEnt_{rated}$  = Rated entering condenser air or water temperature at rated capacity.

$TELv_{required}$  = Required leaving evaporator water outlet temperature to maintain rated capacity.

$TELv_{rated}$  = Rated leaving evaporator water outlet temperature at rated capacity.

**1.22.17.15 Field: Design Chilled Water Outlet Temperature**

This numeric field contains the combustion turbine chiller's evaporator outlet design temperature in Celsius.

**1.22.17.16 Field: Design Chilled Water Flow Rate**

For variable volume chiller this is the maximum flow and for constant flow chiller this is the design flow rate. The units are in cubic meters per second.

#### 1.22.17.17 Field: Design Condenser Water Flow Rate

This numeric field contains the combustion turbine chiller's design condenser water flow rate in cubic meters per second. This field can be autosized. This field is not used for Condenser Type = AirCooled or EvaporativelyCooled.

#### 1.22.17.18 Capacity Ratio Curve

The Capacity Ratio Curve is a quadratic equation that determines the Ratio of Available Capacity to Nominal Capacity. The defining equation is:

$$AvailToNominalCapacityRatio = C_1 + C_2 \Delta_{temp} + C_3 \Delta_{temp}^2 \quad (55)$$

Where the Delta Temperature is defined as:

$$FullLoadtoPowerRatio = C_1 + C_2 AvailToNominalCapRatio + C_3 AvailToNominalCapRatio^2 \quad (56)$$

TempCondIn = Temperature entering the condenser (water or air temperature depending on condenser type).

TempCondInDesign = Design Condenser Inlet Temperature from User input above.

TempEvapOut = Temperature leaving the evaporator.

TempEvapOutDesign = Design Chilled Water Outlet Temperature from User input above.

TempRiseCoefficient = User Input from above.

The following three fields contain the coefficients for the quadratic equation.

#### 1.22.17.19 Field: Coefficient 1 of Capacity Ratio Curve

This numeric field contains the first coefficient for the capacity ratio curve.

#### 1.22.17.20 Field: Coefficient 2 of Capacity Ratio Curve

This numeric field contains the second coefficient for the capacity ratio curve.

#### 1.22.17.21 Field: Coefficient 3 of Capacity Ratio Curve

This numeric field contains the third coefficient for the capacity ratio curve.

#### 1.22.17.22 Power Ratio Curve

The Power Ratio Curve is a quadratic equation that determines the Ratio of Full Load to Power. The defining equation is:

$FracFullLoadPower = C_1 + C_2 PartLoadRatio + C_3 PartLoadRatio^2$  The following three fields contain the coefficients for the quadratic equation.

#### 1.22.17.23 Field: Coefficient 1 of Power Ratio Curve

This numeric field contains the first coefficient for the power ratio curve.

#### 1.22.17.24 Field: Coefficient 2 of Power Ratio Curve

This numeric field contains the second coefficient for the power ratio curve.

#### 1.22.17.25 Field: Coefficient 3 of Power Ratio Curve

This numeric field contains the third coefficient for the power ratio curve.

#### 1.22.17.26 Full Load Ratio Curve

The Full Load Ratio Curve is a quadratic equation that determines the fraction of full load power. The defining equation is:

$$FuelEnergyInput = PLoad * (FIC_1 + FIC_2 RLoad + FIC_3 RLoad^2) * (TBFIC_1 + TBFIC_2 AT_{air} + TBFIC_3 AT_{air}^2) \quad (57)$$

The following three fields contain the coefficients for the quadratic equation.

#### 1.22.17.27 Field: Coefficient 1 of Full Load Ratio Curve

This numeric field contains the first coefficient for the full load ratio curve.

#### 1.22.17.28 Field: Coefficient 2 of Full Load Ratio Curve

This numeric field contains the second coefficient for the full load ratio curve.

**1.22.17.29 Field: Coefficient 3 of Full Load Ratio Curve**

This numeric field contains the third coefficient for the full load ratio curve.

**1.22.17.30 Field: Chilled Water Outlet Temperature Lower Limit**

This numeric field contains the lower limit for the evaporator outlet temperature. This temperature acts as a cut off for heat transfer in the evaporator, so that the fluid doesn't get too cold.

**1.22.17.31 Fuel Input Curve**

The Fuel Input Curve is a polynomial equation that determines the Ratio of Fuel Input to Energy Output. The equation combines both the Fuel Input Curve Coefficients and the Temperature Based Fuel Input Curve Coefficients. The defining equation is:

$$ExhaustFlowRate = GTCapacity * (C_1 + C_2 AT_{air} + C_3 AT_{air}^2) \quad (58)$$

where FIC represents the Fuel Input Curve Coefficients, TBFIC represents the Temperature Based Fuel Input Curve Coefficients, Rload is the Ratio of Load to Combustion Turbine Engine Capacity, and  $AT_{air}$  is the difference between the current ambient and design ambient temperatures.

The following three fields contain the coefficients for the fuel input curve.

**1.22.17.32 Field: Coefficient 1 of Fuel Input Curve**

This numeric field contains the first coefficient for the Fuel Input Curve.

**1.22.17.33 Field: Coefficient 2 of Fuel Input Curve**

This numeric field contains the second coefficient for the Fuel Input Curve.

**1.22.17.34 Field: Coefficient 3 of Fuel Input Curve**

This numeric field contains the third coefficient for the Fuel Input Curve.

The following three fields contain the coefficients for the temperature based fuel input curve.

**1.22.17.35 Field: Coefficient 1 of Temperature Based Fuel Input Curve**

This numeric field contains the first coefficient for the Temperature Based Fuel Input Curve.

**1.22.17.36 Field: Coefficient 2 of Temperature Based Fuel Input Curve**

This numeric field contains the second coefficient for the Temperature Based Fuel Input Curve.

**1.22.17.37 Field: Coefficient 3 of Temperature Based Fuel Input Curve**

This numeric field contains the third coefficient for the Temperature Based Fuel Input Curve.

**1.22.17.38 Exhaust Flow Curve**

The Exhaust Flow Curve is a quadratic equation that determines the Ratio of Exhaust Gas Flow Rate to Engine Capacity. The defining equation is:

$$ExhaustTemperature = (C_1 + C_2 RLoad + C_3 RLoad^2) * (TBC_1 + TBC_2 AT_{air} + TBC_3 AT_{air}^2) - 273.15$$

where GTCapacity is the Combustion Turbine Engine Capacity, and  $AT_{air}$  is the difference between the current ambient and design ambient temperatures.

**1.22.17.39 Field: Coefficient 1 of Exhaust Flow Curve**

This numeric field contains the first coefficient for the Exhaust Flow Curve.

**1.22.17.40 Field: Coefficient 2 of Exhaust Flow Curve**

This numeric field contains the second coefficient for the Exhaust Flow Curve.

**1.22.17.41 Field: Coefficient 3 of Exhaust Flow Curve**

This numeric field contains the third coefficient for the Exhaust Flow Curve.

#### 1.22.17.42 Exhaust Gas Temperature Curve

The Exhaust Gas Temperature Curve is a polynomial equation that determines the Exhaust Gas Temperature. The equation combines both the Exhaust Gas Temperature Curve Coefficients (Based on the Part Load Ratio) and the (Ambient) Temperature Based Exhaust Gas Temperature Curve Coefficients. The defining equation is:

$$RecoveryLubeEnergy = PLoad * (C_1 + C_2RL + C_3RL^2)$$

where C represents the Exhaust Gas Temperature Curve Coefficients, TBC are the Temperature Based Exhaust Gas Temperature Curve Coefficients, RLoad is the Ratio of Load to Combustion Turbine Engine Capacity, and  $AT_{air}$  is the difference between the actual ambient and design ambient temperatures.

#### 1.22.17.43 Field: Coefficient 1 of Exhaust Gas Temperature Curve

This numeric field contains the first coefficient for the Exhaust Gas Temperature Curve.

#### 1.22.17.44 Field: Coefficient 2 of Exhaust Gas Temperature Curve

This numeric field contains the second coefficient for the Exhaust Gas Temperature Curve.

#### 1.22.17.45 Field: Coefficient 3 of Exhaust Gas Temperature Curve

This numeric field contains the third coefficient for the Exhaust Gas Temperature Curve.

#### 1.22.17.46 Field: Coefficient 1 of Temperature Based Exhaust Gas Temperature Curve

This numeric field contains the first coefficient for the Temperature Based Exhaust Gas Temperature Curve.

#### 1.22.17.47 Field: Coefficient 2 of Temperature Based Exhaust Gas Temperature Curve

This numeric field contains the second coefficient for the Temperature Based Exhaust Gas Temperature Curve.

#### 1.22.17.48 Field: Coefficient 3 of Temperature Based Exhaust Gas Temperature Curve

This numeric field contains the third coefficient for the Temperature Based Exhaust Gas Temperature Curve.

#### 1.22.17.49 Recovery Lubricant Heat Curve

The Recovery Lubricant Heat Curve is a quadratic equation that determines the recovery lube energy. The defining equation is:

$$UAToCapacityRatio = C_1 GasTurbineEngineCapacity^{C_2} \quad (59)$$

where Pload is the engine load and RL is the Ratio of Load to Combustion Turbine Engine Capacity

The following three fields contain the coefficients for the quadratic equation.

#### 1.22.17.50 Field: Coefficient 1 of Recovery Lube Heat Curve

This numeric field contains the first coefficient for the Recovery Lube Heat curve.

#### 1.22.17.51 Field: Coefficient 2 of Recovery Lube Heat Curve

This numeric field contains the second coefficient for the Recovery Lube Heat curve.

#### 1.22.17.52 Field: Coefficient 3 of Recovery Lube Heat Curve

This numeric field contains the third coefficient for the Recovery Lube Heat curve.

#### 1.22.17.53 U-Factor Times Area Curve Curve

The U-Factor Times Area Curve (UA) is an equation that determines the overall heat transfer coefficient for the exhaust gasses with the stack. The heat transfer coefficient ultimately helps determine the exhaust stack temperature. The defining equation is:

$$AvailableCoolingCapacity = NominalCoolingCapacity * CoolCapfT(T_{cw,l}, T_{cond}) \quad (60)$$

The following two fields contain the coefficients for the equation.

#### 1.22.17.54 Field: Coefficient 1 of U-Factor Times Area Curve

This numeric field contains the first coefficient for the overall heat transfer coefficient curve.

#### 1.22.17.55 Field: Coefficient 2 of U-Factor Times Area Curve

This numeric field contains the second (exponential) coefficient for the overall heat transfer coefficient curve.

#### 1.22.17.56 Field: Gas Turbine Engine Capacity

This numeric field contains the capacity of the gas turbine engine in watts.

#### 1.22.17.57 Field: Maximum Exhaust Flow per Unit of Power Output

This numeric field contains the maximum exhaust gas mass flow rate per kilowatt of power out.

#### 1.22.17.58 Field: Design Steam Saturation Temperature

This numeric field contains the design steam saturation temperature in Celsius.

#### 1.22.17.59 Field: Fuel Higher Heating Value

This numeric field contains the higher heating value of the fuel used in kJ/kg.

#### 1.22.17.60 Field: Design Heat Recovery Water Flow Rate

This is the design heat recovery water flow rate if the heat recovery option is being simulated. If this value is greater than 0.0, a heat recovery loop must be specified and attached to the chiller using the next two node fields. The units are in cubic meters per second.

#### 1.22.17.61 Field: Heat Recovery Inlet Node Name

This alpha field contains the identifying name for the heat recovery side inlet. If a loop is connected, then the jacket and lubricant heat will be recovered. There is no need for an effectiveness term, since the jacket and lubricant recovered heat energies are the actual recovered energies.

#### 1.22.17.62 Field: Heat Recovery Outlet Node Name

This alpha field contains the identifying name for the heat recovery side outlet.

#### 1.22.17.63 Field: Chiller Flow Mode

This choice field determines how the chiller operates with respect to the intended fluid flow through the device's evaporator. There are three different choices for specifying operating modes for the intended flow behavior: "NotModulated," "ConstantFlow," and "LeavingSetpointModulated." NotModulated is useful for either variable or constant speed pumping arrangements where the chiller is passive in the sense that although it makes a nominal request for its design flow rate it can operate at varying flow rates. ConstantFlow is useful for constant speed pumping arrangements where the chiller's request for flow is stricter and can increase the overall loop flow. LeavingSetpointModulated changes the chiller model to internally vary the flow rate so that the temperature leaving the chiller matches a setpoint. In all cases the operation of the external plant system can also impact the flow through the chiller -- for example if the relative sizes and operation are such that flow is restricted and the requests cannot be met. The default, if not specified, is NotModulated.

#### 1.22.17.64 Field: Fuel Type

This alpha field determines the type of fuel that the chiller uses. Valid choices are **NaturalGas**, **PropaneGas**, **Diesel**, **Gasoline**, **FuelOil#1**, **FuelOil#2**, **OtherFuel1** or **OtherFuel2**. The default is **NaturalGas**.

#### 1.22.17.65 Field: Heat Recovery Maximum Temperature

This field sets the maximum temperature that this piece of equipment can produce for heat recovery. The idea behind this field is that the current models do not take temperatures into account for availability and they just pass Q's around the loop without a temperature limit. This temperature limit puts an upper bound on the recovered heat and limits the max temperatures leaving the component.

As temperatures in the loop approach the maximum temperature, the temperature difference between the entering water and the surfaces in the piece of equipment becomes smaller. For the given heat recovery flow rate and that temperature difference the amount of heat recovered will be reduced, and eventually there will be no heat recovered when the entering water temperature is equal to the maximum temperature specified by the user in this field. The reduced amount of heat recovered will diminish if the temperature of the loop approach is the maximum temperature, and this will show up in the reporting. This allows the user to set the availability or the quality of the heat recovered for usage in other parts of the system or to heat domestic hot water supply.

The temperature is specified in degrees C.

#### 1.22.17.66 Field: Sizing Factor

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be

altered by the sizing factor are: Nominal Capacity, Design Chilled Water Flow Rate and Design Condenser Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

### 1.22.17.67 Field: Basin Heater Capacity

This numeric field contains the capacity of the chiller's electric basin heater in watts per degree Kelvin. This field only applies for Condenser Type = EvaporativelyCooled. This field is used in conjunction with the Basin Heater Setpoint Temperature described in the following field. The basin heater electric power is equal to this field multiplied by the difference between the basin heater set point temperature and the outdoor dry-bulb temperature. The basin heater only operates when the chiller is off, regardless of the basin heater schedule described below. The basin heater capacity must be greater than or equal to zero, with a default value of zero if this field is left blank.

### 1.22.17.68 Field: Basin Heater Setpoint Temperature

This numeric field contains the set point temperature (°C) for the basin heater described in the previous field. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater is active when the outdoor air dry-bulb temperature falls below this setpoint temperature, as long as the chiller is off. This set point temperature must be greater than or equal to 2°C, and the default value is 2°C if this field is left blank.

### 1.22.17.69 Field: Basin Heater Operating Schedule Name

This alpha field contains the name of the basin heater operating schedule. This field only applies for Condenser Type = EvaporativelyCooled. The basin heater operating schedule is assumed to be an on/off schedule and the heater is available to operate any time the schedule value is greater than 0. The basin heater operates when scheduled on and the outdoor air dry-bulb temperature is below the set point temperature described in the previous field. If this field is left blank, the basin heater is available to operate throughout the simulation. Regardless of this schedule, the basin heater may only operate when the chiller is off.

An example of this statement in an IDF is:

These chiller output variables are defined above under "Generic Chiller Outputs." The Fuel Type input will determine which fuel type is displayed in the output. In this example with the user choice of **NaturalGas**, you will have **Gas** Consumption.

### 1.22.19 ChillerHeater:Absorption:DirectFired

This chiller is a direct fired absorption chiller-heater which is modeled using performance curves similar to the equivalent chiller in DOE-2.1E. This type of chiller is unusual for EnergyPlus, because it may be used in the same plant on both a chilled water supply branch and a hot water supply branch. The chiller has six node connections for chilled water, condenser water, and hot water, and can provide simultaneous heating and cooling. During simultaneous operation, the heating capacity is reduced as the cooling load increases (for more details see below). Some equations are provided below to help explain the function of the various performance curves. For a detailed description of the algorithm and how the curves are used in the calculations, please see the Engineering Reference.

#### 1.22.19.1 Field: Name

This alpha field contains the identifying name for the chiller.

#### 1.22.19.2 Field: Nominal Cooling Capacity

This numeric field contains the nominal cooling capability of the chiller in Watts.

#### 1.22.19.3 Field: Heating to Cooling Capacity Ratio

A positive fraction that represents the ratio of the heating capacity divided by the cooling capacity at rated conditions. The default is 0.8.

#### 1.22.19.4 Field: Fuel Input to Cooling Output Ratio

A positive fraction that represents the ratio of the instantaneous cooling fuel used divided by the cooling capacity at rated conditions. The default is 0.97.

#### 1.22.19.5 Field: Fuel Input to Heating Output Ratio

A positive fraction that represents the ratio of the instantaneous heating fuel used divided by the nominal heating capacity. The default is 1.25.

#### 1.22.19.6 Field: Electric Input to Cooling Output Ratio

A positive fraction that represents the ratio of the instantaneous electricity used divided by the cooling capacity at rated conditions. If the chiller is both heating and cooling only the greater of the computed cooling and heating electricity is used. The default is 0.01.

#### 1.22.19.7 Field: Electric Input to Heating Output Ratio

A positive fraction that represents the ratio of the instantaneous electricity used divided by the nominal heating capacity. If the chiller is both heating and cooling, the greater of the cooling electricity and heating electricity is used. The default is 0.0.

#### 1.22.19.8 Field: Chilled Water Inlet Node Name

This required alpha field contains the identifying name for the chiller chilled water side inlet node. This node name must be the same as the inlet node name for the chilled water supply branch on which this chiller is placed.

#### 1.22.19.9 Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the chiller chilled water side outlet node.

#### 1.22.19.10 Field: Condenser Inlet Node Name

This required alpha field contains the identifying name for the chiller condenser side inlet node. If the Chiller is AirCooled, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air dry-bulb temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air dry-bulb temperature is taken directly from the weather data.

#### 1.22.19.11 Field: Condenser Outlet Node Name

This required alpha field contains the identifying name for the chiller condenser side outlet node.

#### 1.22.19.12 Field: Hot Water Inlet Node Name

This required alpha field contains the identifying name for the chiller-heater hot water side inlet node. This node name must be the same as the inlet node name for the hot water supply branch on which this chiller-heater is placed.

#### 1.22.19.13 Field: Hot Water Outlet Node Name

This required alpha field contains the identifying name for the chiller-heater hot water side outlet node.

#### 1.22.19.14 Field: Minimum Part Load Ratio

A positive fraction that represents the minimum cooling or heating output possible when operated continually at rated temperature conditions divided by the available cooling or heating capacity at those same conditions. If the load on the chiller is below this fraction, the chiller will cycle. If the chiller is simultaneously heating and cooling, the greater part load ratio will be used. The default is 0.1.

#### 1.22.19.15 Field: Maximum Part Load Ratio

A positive fraction that represents the maximum cooling or heating output possible when operated continually at rated temperature conditions divided by the available cooling or heating capacity at those same conditions. If greater than 1.0, the chiller is typically thought of as capable of being overloaded. The default is 1.0.

#### 1.22.19.16 Field: Optimum Part Load Ratio

A positive fraction that represents the optimum cooling or heating output possible when operated continually at rated temperature conditions divided by the available cooling or heating capacity at those same conditions. It represents the most desirable operating point for the chiller. The default is 1.0.

#### 1.22.19.17 Field: Design Entering Condenser Water Temperature

The temperature in degrees C of the water entering the condenser of the chiller when operating at design conditions. This is usually based on the temperature delivered by the cooling tower in a water cooled application. The default is 29C.

#### 1.22.19.18 Field: Design Leaving Chilled Water Temperature

The temperature in degrees C of the water leaving the evaporator of the chiller when operating at design conditions; also called the chilled water supply temperature or leaving chilled water temperature. The default is 7C.

#### 1.22.19.19 Field: Design Chilled Water Flow Rate

For variable volume this is the max flow and for constant flow this is the chilled water flow rate in  $\text{m}^3/\text{s}$ .

#### 1.22.19.20 Field: Design Condenser Water Flow Rate

The water flow rate at design conditions through the condenser in  $\text{m}^3/\text{s}$ . This field can be autosized. This field can be autosized. This field is not used for Condenser Type=AirCooled.

#### 1.22.19.21 Field: Design Hot Water Flow Rate

The water flow rate at design conditions through the heater side in  $\text{m}^3/\text{s}$ .

#### 1.22.19.22 Field: Cooling Capacity Function of Temperature Curve Name

The CoolCapfT curve represents the fraction of the cooling capacity of the chiller as it varies by temperature. The curve is normalized so that at design conditions the value of the curve should be 1.0. The curve is usually a biquadratic or bilinear curve with the input variables being the leaving chilled water temperature and either the entering or leaving condenser water temperature (see *Temperature Curve Input Variable* below). The available cooling capacity is computed as follows:

$$\text{CoolFuelInput} = \text{AvailCoolCap} \cdot \text{RunFrac} \cdot \text{CFIR} \cdot \text{CFIRfT}(T_{\text{cw},1}, T_{\text{cond}}) \cdot \text{CFIRfPLR}(\text{CPLR}) \quad (61)$$

#### 1.22.19.23 Field: Fuel Input to Cooling Output Ratio Function of Temperature Curve Name

The CFIRfT curve represents the fraction of the fuel input to the chiller at full load as it varies by temperature. The curve is normalized so that at design conditions the value of the curve should be 1.0. The curve is usually a biquadratic or bilinear curve with the input variables being the leaving chilled water temperature and either the entering or leaving condenser water temperature (see *Temperature Curve Input Variable* below).

#### 1.22.19.24 Field: Fuel Input to Cooling Output Ratio Function of Part Load Ratio Curve Name

The CFIRfPLR curve represents the fraction of the fuel input to the chiller as the load the chiller varies but the operating temperatures remain at the design values. The curve is normalized so that at full load the value of the curve should be 1.0. The curve is usually linear or quadratic. The cooling fuel input to the chiller is computed as follows:

$$\begin{aligned} CoolElectricPower = \\ NomCoolCap \cdot RunFrac \cdot CEIR \cdot CEIRfT(T_{cw,l}, T_{cond}) \cdot CEIRfPLR(CPLR) \end{aligned} \quad (62)$$

**1.22.19.25 Field: Electric Input to Cooling Output Ratio Function of Temperature Curve Name**

The ElecCoolFT curve represents the fraction of the electricity to the chiller at full load as it varies by temperature. The curve is normalized so that at design conditions the of the curve should be 1.0. The curve is usually a biquadratic or bilinear curve with the input variables being the leaving chilled water temperature and either the entering or leaving condenser water temperature (see *Temperature Curve Input Variable* below).

**1.22.19.26 Field: Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve Name**

The ElecCoolFPLR curve represents the fraction of the electricity to the chiller as the load on the chiller varies but This operating temperatures remain at the design values. The curve is normalized so that at full load the value of the curve should be 1.0. The curve is usually linear or quadratic. The cooling electric input to the chiller is computed as follows:

$$AvailHeatCap = NomCoolCap \cdot HeatCoolCapRatio \cdot HeatCapfCPLR(CPLRh) \quad (63)$$

**1.22.19.27 Field: Heating Capacity Function of Cooling Capacity Curve Name**

The HeatCapFCool curve represents how the heating capacity of the chiller varies with cooling capacity when the chiller is simultaneous heating and cooling. The curve is normalized so an input of 1.0 represents the nominal cooling capacity and an output of 1.0 represents the full heating capacity (see the Heating to Cooling Capacity Ratio input) The curve is usually linear or quadratic. The available heating capacity is computed as follows:

$$HeatFuelInput = AvailHeatCap \cdot HFIR \cdot HFIRfHPLR(HPLR) \quad (64)$$

**1.22.19.28 Field: Fuel Input to Heat Output Ratio During Heating Only Operation Curve Name**

When the chiller is operating as only a heater, the curve is used to represent the fraction of fuel used as the heating load varies. It is normalized so that a value of 1.0 is the full available heating capacity. The curve is usually linear or quadratic and will probably be similar to a boiler curve for most chillers.

$$AvailCoolCap = NomCoolCap \cdot CoolCapfT(T_{cw,l}, T_{cond}) \quad (65)$$

**1.22.19.29 Field: Temperature Curve Input Variable**

This field sets the second independent variable in the three temperature dependent performance curves to either the leaving or entering condenser water temperature. Manufacturers express the performance of their chillers using either the leaving condenser water temperature (to the tower) or the entering condenser water temperature (from the tower). Valid choices for this field are: LeavingCondenser or EnteringCondenser. It is important that the performance curves and this field are consistent with each other. The default is EnteringCondenser.

**1.22.19.30 Field: Condenser Type**

The condenser can either be air cooled or connected to a cooling tower. This alpha field contains the keyword for the type of condenser, either AirCooled, or WaterCooled. The default is WaterCooled.

**1.22.19.31 Field: Chilled Water Temperature Lower Limit**

The chilled water supply temperature in degrees C below which the chiller will shut off. The default is 2C.

**1.22.19.32 Field: Fuel Higher Heating Value**

The fuel higher heating value in kJ/kg. *This field is not currently used.*

**1.22.19.33 Field: Chiller Flow Mode**

This field is deprecated and is not used.

**1.22.19.34 Field: Fuel Type**

This alpha field determines the type of fuel that the chiller uses. The default is **NaturalGas**. Valid values are **NaturalGas**, **PropaneGas**, **Diesel**, **Gasoline**, **FuelOil#1**, **FuelOil#2**, **OtherFuel1**, **OtherFuel2**.

**1.22.19.35 Field: Sizing Factor**

This optional numeric field allows the user to specify a sizing factor for this component. The sizing factor is used when the component design inputs are

autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Cooling Capacity, Design Chilled Water Flow Rate, Design Condenser Water Flow Rate and Design Hot Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while continuing to use the autosizing feature.

### 1.22.20 Direct Fired Absorption Chiller Outputs

- HVAC,Average,Chiller Heater Electric Power [W]
- HVAC,Sum,Chiller Heater Electric Energy [J]
- Zone,Meter,Electricity:Plant [J]
- Zone,Meter,Cooling:Electricity [J]
- HVAC,Average,Chiller <Fuel Type> Consumption Rate [W]
- HVAC,Sum,Chiller <Fuel Type> Consumption [J]
- Zone,Meter,<Fuel Type>:Plant [J]
- Zone,Meter,Cooling:<Fuel Type> [J]
- HVAC,Average,Chiller Evaporator Cooling Rate [W]
- HVAC,Sum,Chiller Heater Evaporator Cooling Energy [J]
- Zone,Meter,EnergyTransfer:Plant [J]
- Zone,Meter,Chillers:EnergyTransfer [J]
- HVAC,Average,Chiller Heater Evaporator Inlet Temperature [C]
- HVAC,Average,Chiller Heater Evaporator Outlet Temperature [C]
- HVAC,Average,Chiller Heater Evaporator Mass Flow Rate [kg/s]
- HVAC,Average,Chiller Heater Condenser Heat Transfer Rate [W]

- HVAC,Sum,Chiller Heater Condenser Heat Transfer Energy [J]
- Zone,Meter,HeatRejection:EnergyTransfer [J]

The following output is applicable only for air-cooled chillers

- HVAC,Average,Chiller Heater Condenser Inlet Temperature [C]

The following three outputs are only available for water-cooled chillers

- HVAC,Average,Chiller Heater Condenser Inlet Temperature [C]
- HVAC,Average,Chiller Heater Condenser Outlet Temperature [C]
- HVAC,Average,Chiller Heater Condenser Mass Flow Rate [kg/s]

Outputs specific to Direct Fired Absorption Chiller

- HVAC,Average,Chiller Heater Runtime Fraction []

Outputs specific to Direct Fired Absorption Chiller during cooling operation

- HVAC,Average,Chiller Heater Cooling <Fuel Type> Rate [W]
- HVAC,Sum,Chiller Heater Cooling <Fuel Type> Consumption [J]
- HVAC,Average,Chiller Heater Cooling Electric Power [W]
- HVAC,Sum,Chiller Heater Cooling Electric Energy [J]
- HVAC,Average,Chiller Heater Cooling Part Load Ratio
- HVAC,Average,Chiller Heater Cooling Rate [W]
- HVAC,Average,Chiller Heater Cooling COP [W/W]

Outputs specific to Direct Fired Absorption Chiller during heating operation

- HVAC,Average,Chiller Heater Heating Rate [W]
- HVAC,Sum,Chiller Heater Heating Energy [J]
- HVAC,Average,Chiller Heater Heating <Fuel Type> Rate [W]
- HVAC,Sum,Chiller Heater Heating <Fuel Type> Energy [J]
- HVAC,Average,Chiller Heater Heating Electric Power [W]
- HVAC,Sum,Chiller Heater Heating Electric Energy [J]
- HVAC,Average,Chiller Heater Heating Part Load Ratio []
- HVAC,Average,Chiller Heater Heating Rate [W]
- HVAC,Average,Chiller Heater Heating Inlet Temperature [C]
- HVAC,Average,Chiller Heater Heating Outlet Temperature [C]
- HVAC,Average,Chiller Heater Heating Mass Flow Rate [kg/s]

The "Chiller" output variables are defined above under "Generic Chiller Outputs." The specific "Direct Fired Absorption Chiller" output variables and exceptions to the generic outputs are defined below.

#### **1.22.20.1 Chiller Heater Electric Power [W]**

#### **1.22.20.2 Chiller Heater Electric Energy [J]**

These outputs are the electric power input to the chiller when operating in cooling mode, heating mode, or both. This value is not metered, but the separate cooling and heating electric consumption are metered (see below).

#### **1.22.20.3 Chiller Heater <Fuel Type> Rate [W]**

#### **1.22.20.4 Chiller Heater <Fuel Type> Energy [J]**

These outputs are the fuel input to the chiller when operating in cooling mode, heating mode, or both depending on the fuel type entered. This value is not metered, but the separate cooling and heating fuel consumption are metered (see below).

#### **1.22.20.5 Chiller Heater Runtime Fraction []**

This is the average fraction of the time period during which the direct fired absorption chiller-heater was operating in either cooling mode, heating mode, or both.

#### **1.22.20.6 Chiller Heater Cooling <Fuel Type> Rate [W]**

#### **1.22.20.7 Chiller Heater Cooling <Fuel Type> Energy [J]**

These outputs are the fuel input to the direct fired absorption chiller to serve cooling operation. Consumption is metered on Cooling:<Fuel Type>, <Fuel Type>:Plant, and <Fuel Type>:Facility.

#### **1.22.20.8 Chiller Heater Cooling Electric Power [W]**

#### **1.22.20.9 Chiller Heater Cooling Electric Energy [J]**

These outputs are the electricity input to the direct fired absorption chiller to serve cooling operation. Consumption is metered on Cooling:Electricity, Electricity:Plant, and Electricity:Facility.

#### **1.22.20.10 Chiller Heater Cooling Rate [W]**

This is the average available cooling capacity for the reported time period.

#### **1.22.20.11 Chiller Heater Cooling Part Load Ratio**

This is the average cooling load (Chiller Evaporator Cooling Rate [W]) divided by the average available cooling capacity (Chiller Heater Cooling Rate [W]) for the reported time period.

#### **1.22.20.12 Chiller Heater Cooling COP**

This is the average coefficient of performance for the chiller in cooling operation, calculated as the average cooling load (Chiller Evaporator Cooling Rate [W]) divided by the average fuel consumption during cooling (Direct Fired Absorption Chiller Cooling <Fuel Type> Consumption Rate [W]) for the reported time period. If the chiller cooling fuel consumption rate (denominator) is zero, then this output variable is set to zero.

#### **1.22.20.13 Chiller Heater Heating Rate [W]**

#### **1.22.20.14 Chiller Heater Heating Energy [J]**

These outputs are the heating delivered by the direct fired absorption chiller-heater to serve heating operation. Energy is metered on Boilers:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

#### **1.22.20.15 Chiller Heater Heating <Fuel Type> Rate [W]**

#### **1.22.20.16 Chiller Heater Heating <Fuel Type> Energy [J]**

These outputs are the fuel input to the direct fired absorption chiller-heater to serve heating operation. Consumption is metered on Heating:<Fuel Type>, <Fuel Type>:Plant, and <Fuel Type>:Facility.

#### **1.22.20.17 Chiller Heater Heating Electric Power [W]**

#### **1.22.20.18 Chiller Heater Heating Electric Energy [J]**

These outputs are the electric power input to the direct fired absorption chiller to serve heating operation. Consumption is metered on Heating:Electricity, Electricity:Plant, and Electricity:Facility.

#### **1.22.20.19 Chiller Heater Heating Rate [W]**

This is the average available heating capacity for the reported time period.

#### **1.22.20.20 Chiller Heater Heating Part Load Ratio**

This is the average heating load (Chiller Heater Heating Rate [W]) divided by the average available heating capacity (Chiller Heater Heating Rate [W]) for the reported time period.

#### **1.22.20.21 Chiller Heater Heating Inlet Temperature [C]**

#### 1.22.20.22 Chiller Heater Heating Outlet Temperature [C]

#### 1.22.20.23 Chiller Heater Heating Mass Flow Rate [kg/s]

These outputs are the hot water inlet and outlet temperatures and flow rate for the direct fired absorption chiller-heater during heating mode operation.

### 1.22.21 ChillerHeater:Absorption:DoubleEffect

This chiller is an exhaust fired absorption chiller-heater which is modeled using performance curves similar to the direct fired absorption chiller in DOE-2.1E. The model uses the exhaust gas output from MicroTurbine. This type of chiller is unusual for EnergyPlus, because it may be used in the same plant on both a chilled water supply branch and a hot water supply branch. The chiller has six node connections for chilled water, condenser water, and hot water, and can provide simultaneous heating and cooling. During simultaneous operation, the heating capacity is reduced as the cooling load increases (for more details see below). Some equations are provided below to help explain the function of the various performance curves. For a detailed description of the algorithm and how the curves are used in the calculations, please see the Engineering Reference.

#### 1.22.21.1 Field: Name

This alpha field contains the identifying name for the chiller.

#### 1.22.21.2 Field: Nominal Cooling Capacity

This numeric field contains the nominal cooling capability of the chiller in Watts. Autosize can be used for this field.

#### 1.22.21.3 Field: Heating to Cooling Capacity Ratio

A positive fraction that represents the ratio of the heating capacity divided by the cooling capacity at rated conditions. The default is 0.8.

#### 1.22.21.4 Field: Thermal Energy Input to Cooling Output Ratio

A positive fraction that represents the ratio of the instantaneous cooling Thermal Energy used divided by the cooling capacity at rated conditions. The default is 0.97.

#### 1.22.21.5 Field: Thermal Energy Input to Heating Output Ratio

A positive fraction that represents the ratio of the instantaneous heating Thermal Energy used divided by the nominal heating capacity. The default is 1.25.

#### 1.22.21.6 Field: Electric Input to Cooling Output Ratio

A positive fraction that represents the ratio of the instantaneous electricity used divided by the cooling capacity at rated conditions. If the chiller is both heating and cooling only the greater of the computed cooling and heating electricity is used. The default is 0.01.

#### 1.22.21.7 Field: Electric Input to Heating Output Ratio

A positive fraction that represents the ratio of the instantaneous electricity used divided by the nominal heating capacity. If the chiller is both heating and cooling, the greater of the cooling electricity and heating electricity is used. The default is 0.0.

#### 1.22.21.8 Field: Chilled Water Inlet Node Name

This required alpha field contains the identifying name for the chiller chilled water side inlet node. This node name must be the same as the inlet node name for the chilled water supply branch on which this chiller is placed.

#### 1.22.21.9 Field: Chilled Water Outlet Node Name

This required alpha field contains the identifying name for the chiller chilled water side outlet node.

#### 1.22.21.10 Field: Condenser Inlet Node Name

This required alpha field contains the identifying name for the chiller condenser side inlet node. If the Chiller is AirCooled, the node name specified must also be specified in an OutdoorAir:Node object where the height of the node is taken into consideration when calculating outdoor air dry-bulb temperature from the weather data. Alternately, the node name may be specified in an OutdoorAir:NodeList object where the outdoor air dry-bulb temperature is taken directly from the weather data.

#### 1.22.21.11 Field: Condenser Outlet Node Name

This required alpha field contains the identifying name for the chiller condenser side outlet node.

#### 1.22.21.12 Field: Hot Water Inlet Node Name

This required alpha field contains the identifying name for the chiller-heater hot water side inlet node. This node name must be the same as the inlet node name for the hot water supply branch on which this chiller-heater is placed.

#### 1.22.21.13 Field: Hot Water Outlet Node Name

This required alpha field contains the identifying name for the chiller-heater hot water side outlet node.

#### 1.22.21.14 Field: Minimum Part Load Ratio

A positive fraction that represents the minimum cooling or heating output possible when operated continually at rated temperature conditions divided by the available cooling or heating capacity at those same conditions. If the load on the chiller is below this fraction, the chiller will cycle. If the chiller is simultaneously heating and cooling, the greater part load ratio will be used. The default is 0.1.

#### 1.22.21.15 Field: Maximum Part Load Ratio

A positive fraction that represents the maximum cooling or heating output possible when operated continually at rated temperature conditions divided by the available cooling or heating capacity at those same conditions. If greater than 1.0, the chiller is typically thought of as capable of being overloaded. The default is 1.0.

#### 1.22.21.16 Field: Optimum Part Load Ratio

A positive fraction that represents the optimum cooling or heating output possible when operated continually at rated temperature conditions divided by the available cooling or heating capacity at those same conditions. It represents the most desirable operating point for the chiller. The default is 1.0.

#### 1.22.21.17 Field: Design Entering Condenser Water Temperature

The temperature in degrees C of the water entering the condenser of the chiller when operating at design conditions. This is usually based on the temperature delivered by the cooling tower in a water cooled application. The default is 29°C.

#### 1.22.21.18 Field: Design Leaving Chilled Water Temperature

The temperature in degrees C of the water leaving the evaporator of the chiller when operating at design conditions; also called the chilled water supply temperature or leaving chilled water temperature. The default is 7°C.

#### 1.22.21.19 Field: Design Chilled Water Flow Rate

For variable volume this is the max flow and for constant flow this is the chilled water flow rate in  $\text{m}^3/\text{s}$ . This field can be autosized.

#### 1.22.21.20 Field: Design Condenser Water Flow Rate

The water flow rate at design conditions through the condenser in  $\text{m}^3/\text{s}$ . This field can be autosized. This field is not used for Condenser Type=AirCooled.

#### 1.22.21.21 Field: Design Hot Water Flow Rate

The water flow rate at design conditions through the heater side in  $\text{m}^3/\text{s}$ . This field can be autosized.

#### 1.22.21.22 Field: Cooling Capacity Function of Temperature Curve Name

The CoolCapfT curve represents the fraction of the cooling capacity of the chiller as it varies with temperature. The curve is normalized so that at design conditions the value of the curve should be 1.0. The curve is usually a biquadratic or bilinear curve with the input variables being the leaving chilled water temperature and the entering condenser water temperature (see *Temperature Curve Input Variable* below). The available cooling capacity is computed as follows:

$$\begin{aligned} \text{CoolThermalEnergyInput} &= \text{AvailCoolCap} \cdot \text{RunFrac} \cdot \text{TeFIR} \cdot \\ &\text{TeFIRfT}(T_{cw,l}, T_{cond}) \cdot \text{TeFIRfPLR}(CPLR) \end{aligned} \quad (66)$$

#### 1.22.21.23 Field: Thermal Energy Input to Cooling Output Ratio Function of Temperature Curve Name

The TeFIRfT curve represents the fraction of the Thermal Energy Input to the chiller at full load as it varies with temperature. The curve is normalized so that at design conditions the value of the curve should be 1.0. The curve is usually a biquadratic or bilinear curve with the input variables being the leaving chilled water temperature and the entering condenser water temperature (see *Temperature Curve Input Variable* below).

#### 1.22.21.24 Field: Thermal Energy Input to Cooling Output Ratio Function of Part Load Ratio Curve Name

The TeFIRfPLR curve represents the fraction of the Thermal Energy Input to the chiller as the load on the chiller varies but the operating temperatures remain at the design values. The curve is normalized so that at full load the value of the curve should be 1.0. The curve is usually linear or quadratic.

The cooling Thermal Energy Input to the chiller is computed as follows:

$$CoolElectricPower = NomCoolCap \cdot RunFrac \cdot CEIR \cdot CEIRfT(T_{cw,l}, T_{cond}) \cdot CEIRfPLR(CPLR) \quad (67)$$

**1.22.21.25 Field: Electric Input to Cooling Output Ratio Function of Temperature Curve Name**

The CEIRfT curve represents the fraction of the electricity to the chiller at full load as it varies with temperature. The curve is normalized so that at design conditions the of the curve should be 1.0. The curve is usually a biquadratic or bilinear curve with the input variables being the leaving chilled water temperature and either the entering or leaving condenser water temperature (see *Temperature Curve Input Variable* below).

**1.22.21.26 Field: Electric Input to Cooling Output Ratio Function of Part Load Ratio Curve Name**

The CEIRfPLR curve represents the fraction of the electricity to the chiller as the load on the chiller varies but This operating temperatures remain at the design values. The curve is normalized so that at full load the value of the curve should be 1.0. The curve is usually linear or quadratic.

The cooling electric input to the chiller is computed as follows:

$$AvailHeatCap = NomCoolCap \cdot HeatCoolCapRatio \cdot HeatCapfCPLR(CPLRh) \quad (68)$$

**1.22.21.27 Field: Heating Capacity Function of Cooling Capacity Curve Name**

The HeatCapFCPLR curve represents how the heating capacity of the chiller varies with cooling capacity when the chiller is simultaneously heating and cooling. The curve is normalized so an input of 1.0 represents the nominal cooling capacity and an output of 1.0 represents the full heating capacity (see the Heating to Cooling Capacity Ratio input) The curve is usually linear or quadratic.

The available heating capacity is computed as follows:

$$HeatThermalEnergyInput = AvailHeatCap \cdot HFIR \cdot HFIRfHPLR(HPLR) \quad (69)$$

**1.22.21.28 Field: Thermal Energy Input to Heat Output Ratio During Heating Only Operation Curve Name**

When the chiller is operating as only a heater, the curve is used to represent the fraction of Thermal Energy used as the heating load varies. It is normalized so that a value of 1.0 is the full available heating capacity. The curve is usually linear or quadratic and will probably be similar to a boiler curve for most chillers.

The heating Thermal Energy Input to the chiller is computed as follows:

$$TheoreticalFuelUse = \frac{BoilerLoad}{NominalThermalEfficiency} \quad (70)$$

**1.22.21.29 Field: Temperature Curve Input Variable**

This field sets the second independent variable in the three temperature dependent performance curves to the entering condenser water temperature. Manufacturers express the performance of their chillers typically using the entering condenser water temperature (from the tower). ). This alpha field contains the keyword for the type of temperature input variable, , either **EnteringCondenserTemperature**, or **LeavingCondenserTemperature**. The default is EnteringCondenserTemperature.

**1.22.21.30 Field: Condenser Type**

The condenser can either be air cooled or water cooled (connected to a cooling tower). This alpha field contains the keyword for the type of condenser, either AirCooled, or WaterCooled. The default is WaterCooled.

**1.22.21.31 Field: Chilled Water Temperature Lower Limit**

The chilled water supply temperature in degrees C below which the chiller will shut off. The default is 2°C.

**1.22.21.32 Field: Exhaust Source**

This alpha field determines the type of exhaust source the chiller uses. The default is MicroTurbine. Key Generator:MicroTurbine

**1.22.21.33 Field: Exhaust Source Object**

This alpha field shows the name of the Exhaust source object – a Generator:MicroTurbine in this case

**1.22.21.34 Field: Sizing Factor**

This optional numeric field allows the user to specify a sizing factor for this component. Min value should not be less than 0 and here is no max. The default is 1. The sizing factor is used when the component design inputs are autosized: the autosizing calculations are performed as usual and the results are multiplied by the sizing factor. For this component the inputs that would be altered by the sizing factor are: Nominal Cooling Capacity, Design Chilled Water Flow Rate, Design Condenser Water Flow Rate and Design Hot Water Flow Rate. Sizing Factor allows the user to size a component to meet part of the design load while

continuing to use the autosizing feature.

An example of this statement in an IDF is:

```
ChillerHeater:Absorption:DoubleEffect,
  Exh Chiller,           !- Chiller Name
  100000,                !- Nominal Cooling Capacity {W}

### 1.22.22 Exhaust Fired Absorption Chiller Outputs

- HVAC,Average,Chiller Heater Electric Power [W]
- HVAC,Sum,Chiller Heater Electric Energy [J]
- HVAC,Average,Chiller Heater Evaporator Cooling Rate [W]
- HVAC,Sum,Chiller Heater Evaporator Cooling Energy [J]
- HVAC,Average,Chiller Heater Evaporator Inlet Temperature [C]
- HVAC,Average,Chiller Heater Evaporator Outlet Temperature [C]
- HVAC,Average,Chiller Heater Evaporator Mass Flow Rate [kg/s]
- HVAC,Average,Chiller Heater Condenser Heat Transfer Rate [W]
- HVAC,Sum,Chiller Heater Condenser Heat Transfer Energy [J]

The following output is applicable only for air-cooled chillers

- HVAC,Average,Chiller Heater Condenser Inlet Temperature [C]

The following three outputs are only available for water-cooled chillers

- HVAC,Average,Chiller Heater Condenser Inlet Temperature [C]
- HVAC,Average,Chiller Heater Condenser Outlet Temperature [C]
- HVAC,Average,Chiller Heater Condenser Mass Flow Rate [kg/s]

Outputs specific to Exhaust Fired Absorption Chiller

- HVAC,Average,Chiller Heater Runtime Fraction []

Outputs specific to Exhaust Fired Absorption Chiller during cooling operation

- HVAC,Average,Chiller Heater Cooling Electric Power [W]
- HVAC,Sum,Chiller Heater Cooling Electric Energy [J]
- HVAC,Average,Chiller Heater Cooling Part Load Ratio
- HVAC,Average,Chiller Heater Maximum Cooling Rate [W]HVAC,Average,Chiller Heater Cooling Source Heat Transfer Rate [W]
- HVAC,Average, Chiller Heater Cooling Source Heat COP [W/W]
- HVAC,Average, Chiller Heater Source Exhaust Inlet Mass Flow Rate [kg/s]
- HVAC,Average, Chiller Heater Source Exhaust Inlet Temperature [C]

Outputs specific to Exhaust Fired Absorption Chiller during heating operation

- HVAC,Average,Chiller Heater Heating Rate [W]
- HVAC,Sum,Chiller Heater Heating Energy [J]
- HVAC,Average,Chiller Heater Heating Electric Power [W]
- HVAC,Sum,Chiller Heater Heating Electric Energy [J]
- Zone,Meter,Heating:Electricity [J]
- HVAC,Average,Chiller Heater Heating Part Load Ratio
- HVAC,Average,Chiller Heater Maximum Heating Rate [W]
- HVAC,Average,Chiller Heater Heating Source Heat Transfer Rate
- HVAC,Average,Chiller Heater Heating Inlet Temperature [C]
- HVAC,Average,Chiller Heater Heating Outlet Temperature [C]
- HVAC,Average,Chiller Heater Heating Mass Flow Rate [kg/s]

The "Chiller" output variables are defined above under "Generic Chiller Outputs." The specific "Exhaust Fired Absorption Chiller" output variables and exceptions to the generic outputs are defined below.

#### **1.22.22.1 Chiller Heater Electric Power [W]**

#### **1.22.22.2 Chiller Heater Electric Energy [J]**

These outputs are the electric power input to the chiller when operating in cooling mode, heating mode, or both. This value is not metered, but the separate cooling and heating electric consumption are metered (see below).

#### **1.22.22.3 Chiller Heater Runtime Fraction []**

This is the average fraction of the time period during which the Exhaust Fired absorption chiller-heater was operating in either cooling mode, heating mode, or both.

These outputs are the electricity input to the Exhaust Fired absorption chiller heater to serve cooling operation. Consumption is metered on Cooling:Electricity, Electricity:Plant, and Electricity:Facility.

#### **1.22.22.4 Chiller Heater Maximum Cooling Rate [W]**

This is the average available cooling capacity for the reported time period.

#### **1.22.22.5 Chiller Heater Cooling Part Load Ratio []**

This is the average cooling load (Chiller Heater Evaporator Cooling Rate [W]) divided by the average available cooling capacity (Chiller Heater Maximum Cooling Rate [W]) for the reported time period.

#### **1.22.22.6 Chiller Heater Cooling Source Heat COP [W/W]**

This is the average coefficient of performance for the chiller in cooling operation, calculated as the average cooling load (Chiller Heater Evaporator Cooling Rate [W]) divided by the average thermal energy use during cooling (Chiller Heater Cooling Source Heat Transfer Rate [W]) for the reported time period. If the chiller cooling thermal energy use rate (denominator) is zero, then this output variable is set to zero.

#### **1.22.22.7 Chiller Heater Heating Rate [W]**

#### **1.22.22.8 Chiller Heater Heating Energy [J]**

#### **1.22.22.9 Chiller Heater Heating Electric Power [W]**

#### **1.22.22.10 Chiller Heater Heating Electric Energy [J]**

These outputs are the electric power input to the Exhaust Fired absorption chiller to serve heating operation. Consumption is metered on Heating:Electricity, Electricity:Plant, and Electricity:Facility.

#### **1.22.22.11 Chiller Heater Maximum Heating Rate [W]**

This is the average available heating capacity for the reported time period.

#### **1.22.22.12 Chiller Heater Heating Part Load Ratio []**

This is the average heating load (Chiller Heater Heating Rate [W]) divided by the average available heating capacity (Chiller Heater Maximum Heating Rate [W]) for the reported time period.

#### **1.22.22.13 Chiller Heater Heating Inlet Temperature [C]**

#### **1.22.22.14 Chiller Heater Heating Outlet Temperature [C]**

#### **1.22.22.15 Chiller Heater Heating Mass Flow Rate [kg/s]**

These outputs are the hot water inlet and outlet temperatures and flow rate for the Exhaust Fired absorption chiller-heater during heating mode operation.

#### **1.22.22.16 Chiller Heater Heating Heat Recovery Potential Rate (W)**

The heat recovery potential calculated based on Microturbine exhaust temperature and flow rate during heating mode

#### **1.22.22.17 Chiller Heater Heating Source Heat Transfer Rate (W)**

The thermal energy consumption rate required for heating.

#### **1.22.22.18 Chiller Heater Cooling Heat Recovery Potential Rate (W)**

The heat recovery potential calculated based on Microturbine exhaust temperature and flow rate during cooling mode.

#### **1.22.22.19 Chiller Heater Cooling Source Heat Transfer Rate (W)**

The thermal energy consumption rate required for cooling.

#### **1.22.22.20 Chiller Heater Condenser Inlet Temperature [C]**

The condenser (heat rejection) inlet temperature for air-cooled or water chiller heater. For an air-cooled chiller heater, this output would be the dry-bulb temperature of the air entering the condenser coil. For a water cooled chiller heater, this output would be the wet-bulb temperature of the air entering the condenser coil.

#### **1.22.22.21 Chiller Heater Condenser Heat Transfer Energy [J]**

The condenser heat transfer energy is the heat rejected from the chiller heater to either a condenser water loop or through an air-cooled condenser. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period. Chiller Heater Condenser Heat Transfer Energy is metered on HeatRejection:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

#### **1.22.22.22 Chiller Heater Condenser Heat Transfer Rate [W]**

The condenser heat transfer is the rate of heat rejected from the chiller heater to either a condenser water loop or through an air-cooled condenser. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.22.22.23 Chiller Heater Condenser Mass Flow Rate [kg/s]**

This is the condenser coil outlet water mass flow rate in kilograms per second. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### **1.22.22.24 Chiller Heater Condenser Outlet Temperature [C]**

This is the condenser coil outlet water temperature in degrees C. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported

#### 1.22.22.25 Chiller Heater Evaporator Cooling Energy [J]

The evaporator heat transfer is the cooling delivered by the chiller heater. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period. Chiller Heater Evaporator Cooling Energy is metered on Chillers:EnergyTransfer, EnergyTransfer:Plant, and EnergyTransfer:Facility.

#### 1.22.22.26 Chiller Heater Evaporator Cooling Rate [W]

The evaporator heat transfer rate of cooling delivered by the chiller heater. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### 1.22.22.27 Chiller Heater Evaporator Inlet Temperature [C]

The evaporator (chilled water) inlet temperature over the time step being reported.

#### 1.22.22.28 Chiller Heater Evaporator Mass Flow Rate [kg/s]

The evaporator (chilled water) average mass flow rate over the time step being reported

#### 1.22.22.29 Chiller Heater Evaporator Outlet Temperature [C]

The evaporator (chilled water) outlet temperature over the time step being reported

#### 1.22.22.30 Chiller Heater Cooling Electric Energy [J]

The electric power input to the exhaust fired absorption chiller to serve cooling operation. The values are calculated for each HVAC system time step being simulated, and the results are summed across the reporting period. Consumption is metered on Heating:Electricity, Electricity:Plant, and Electricity:Facility.

#### 1.22.22.31 Chiller Heater Cooling Electric Power [W]

The electric power input to the Exhaust Fired absorption chiller to serve cooling operation. This value is calculated for each HVAC system time step being simulated, and the results are averaged for the time step being reported.

#### 1.22.22.32 Chiller Heater Source Exhaust Inlet Mass Flow Rate [kg/s]

The exhaust flow rate from the Micro Turbine

#### 1.22.22.33 Chiller Heater Source Exhaust Inlet Temperature [C]

The exhaust temperature from the Micro Turbine

### 1.22.23 Boiler:HotWater

The boiler model calculates the performance of fuel oil, gas and electric boilers. Boiler performance is based on nominal thermal efficiency. A normalized efficiency performance curve may be used to more accurately represent the performance of non-electric boilers but is not considered a required input. When using the normalized efficiency performance curve, if all coefficients are not required simply set the unused coefficients to 0. For example, an electric boiler could be modeled by setting the nominal thermal efficiency to a value in the range of 0.96 to 1.0. Coefficient A0 in the normalized efficiency performance curve would equal 1 and all other coefficients would be set to 0. Coefficients for other types of non-electric boilers would set a combination of the available coefficients to non-zero values.

#### 1.22.23.1 Field: Name

This required alpha field contains the identifying name for the boiler.

#### 1.22.23.2 Field: Fuel Type

This required choice field specifies the type of fuel used by the boiler. The fuel type can be **Electricity**, **NaturalGas**, **PropaneGas**, **FuelOil#1**, **FuelOil#2**, **Coal**, **Diesel**, **Gasoline**, **OtherFuel1** or **OtherFuel2**.

#### 1.22.23.3 Field: Nominal capacity

This numeric field contains the nominal operating capacity (W) of the boiler. The boiler may be autosized and would require a heating plant sizing object.

#### 1.22.23.4 Fuel Use Equation

The model is based the following two equations:

$$FuelUsed = \frac{TheoreticalFuelUse}{NormalizedBoilerEfficiencyCurveOutput} \quad (71)$$

$$Linear \rightarrow Eff = A_0 + A_1 \cdot PLR \quad (72)$$

### 1.22.23.5 Field: Nominal Thermal Efficiency
