- DEA provides a mathematical programming method for estimating optimal production frontiers and evaluating the relative efficiency of different entities.
- "Benchmarking" package contains all of the main DEA and SFA methods.
- Commands to estimate production frontiers using "Benchmarking" package.

- **RTS:**

change the value in order to examine the different kind of models i.e crs for constant return to scale, vrs for variable return to scale , irs , drs.

## ■ ORIENTATION:

change the value for the orientation that model has i.e in for input, out for output.

- **FRS:**

easily can be calculated efficiency under alternative assumptions about the technology as well, using the RTS option with values `drs`, `irs`, `fdh` and `add`.

1.  $e1 < -dea(x, y)$
2.  $eff(e1)$
3.  $print(e1)$
4.  $summary(e1)$
5.  $peers(e1)$
6.  $lambda(e1)$
7.  $get.number.peers(e1)$

1. solve LP problem and insert DEA results in a matrix
2. select efficiency scores from the results
3. print the matrix with the efficient combinations
4. Summary of efficiencies: number of firm with efficiency=1 and the mean efficiency
5. determine the peers
6. weight information
7. gives the number of peers for every entity that have efficiency=1

## ■ Scale efficiency

```
> e_vrs < -dea(x, y, RTS = ' vrs')
```

```
> e_drs < -dea(x, y, RTS = ' drs')
```

```
> e_crs < -dea(x, y, RTS = ' crs')
```

```
> se < -eff(e_crs)/eff(e_vrs)
```

```
> abs(eff(e_vrs) - eff(e_drs)) < 1e - 4
```

The last command check if DRS eff. is equal to VRS eff.

## ■ Allocative efficiency

```
dea(x, y, RTS = " vrs")
```

```
cost.opt(x, y, w, RTS = " vrs")
```
