The best, though highly imperfect, apparatus we have for exploring one person's meaning making is the interpretive (meaning making) facility of another human being who can develop rapport with that first person and engage with them in some form of dialogic conversation. This affordance in some kinds of research is also linked to a serious threat to validity for those attempting to set up experimental research (i.e. in nomothetic mode). The expectations of researchers, or teachers working with them, are readily transferred to learners, and teacher enthusiasm or cynicism about some innovative approach being evaluated in a teaching-learning context can influence learners' own expectations, which in turn influence their perceptions of the innovation and so influence the learning itself. One common type of study compares learning in two 'comparable' classes where teaching by an innovative ('progressive') approach is compared with teaching through a 'traditional' approach. This immediately creates problems for making a fair comparison whether the teaching is carried out by the same teacher (will they be as equally adept and enthusiastic in both conditions?) or different teachers (who inevitably will bring different skills, and knowledge to their teaching). Added to that, the learners themselves may well react to the novelty of the innovation purely in terms of it being something different from the norm (which may well be welcomed, but could for some learners be perceived as threatening).

However we go about *collecting* data about the ideas, feelings, opinions, attitudes, etc. of others, we can only meaningfully *analyse* that data through the interpretations of other humans. This is what some commentators mean by ‘qualitative’ research (see above): research that relies on the intersubjectivity between researcher and study participants.

Whilst at first sight instruments such as questionnaires seem to avoid this intersubjectivity by presenting statements to be ranked or rated, the items in such instruments are only going to have validity (as statements that are both meaningful to respondents and understood by them *in the sense intended* by the researchers) when derived from previous research which explores what ideas and language will be meaningful for those surveyed – previous research which will necessarily have involved in-depth dialogic approaches (cf. Treagust 1988). Here again, the type of research which would fit under the right hand fork in Fig. 57.3 relies upon earlier rather different work that would fit under the left-hand column.

57.11.3 Mixed Methods: A Third Paradigm, a Subsuming Paradigm or a Rejection of Paradigms?

In recent years, those preferring the notions of quantitative and qualitative paradigms have admitted a ‘new’ paradigm known as mixed methods research: that is, research that employs a combination of quantitative and qualitative features (Creswell 2009; Creswell and Plano Clark 2007; Johnson and Onwuegbuzie 2004). Clearly if we focus on data type, there is nothing of special interest about mixed methods, as studies using quantitative and qualitative data are not themselves novel. It is less clear how a single study could at the same time employ genuinely distinct approaches such that it was at the same time objectivist/positivistic and constructivist-interpretivist if we take the former to suggest a realist ontology and an epistemology which allows claims that research offers in some sense an objective, researcher-independent, account of that reality and if the latter means accepting that the kinds of knowledge about the research foci that are possible are necessarily constructed by human beings and relative to the interpretations of a particular knower (Symonds and Gorard 2008). Given this, the claim that there is a distinct research approach known as ‘mixed methods’ – depending whether it refers simply to data type or something methodologically more substantial – is either fair but of no great significance, or alternatively is important but problematic (Taber 2012a).

This cynicism regarding the *label* of mixed methods derives from seeing it sometimes used in practice to describe a study’s methodology simply because both quantitative and qualitative data are collected. In that situation the label is generally unhelpful as it *at best* stands in place of a more informative label for the methodology adopted and *at worse* substitutes for the choice of an actual substantive coherent methodology. That is, in practice we sometimes find the label 'mixed methods' stands in place of principled thinking about the nature of what is researched and how to best enquire into it.

However, 'mixed methods' has also been positioned as 'an approach to knowledge (theory and practice) that attempts to consider multiple viewpoints, perspectives, positions, and standpoints (always including the standpoints of qualitative and quantitative research)' (Johnson et al. 2007, p. 13). Here mixed methods research is defined as 'the type of research in which a researcher or team of researchers combines elements of qualitative and quantitative research approaches (e.g., use of qualitative and quantitative viewpoints, data collection, analysis, inference techniques) for the broad purposes of breadth and depth of understanding and corroboration' (p. 123). Clearly the discussion here is not restricted to types of data, as presumably the 'standpoints of qualitative and quantitative research' relate to ontological and epistemological issues (are we dealing with the kind of things that can be countered and/or measured?; are we enquiring into something that will require intersubjectivity as an 'instrument' to elicit data?).

The position taken in this chapter, developed further below, is that such choices cannot be established in the abstract, but need to be addressed in the context of particular studies. As a field, science education cannot be well served either by limiting data to be collected to quantitative or qualitative forms; and nor can it progress by committing to the 'standpoints of qualitative [or] quantitative research' independently of the particular questions being addressed. However, if adopting 'mixed methods' as a paradigm (Johnson and Onwuegbuzie 2004) for educational research is taken to mean that we include within our methodological repertoire a wide range of approaches, from which to select according to the need of particular studies, then this fits well with the stance adopted here. The term mixed methods is perhaps unfortunate, as this approach is less a matter of 'mixing' our methods, than of making principled choices of methodology on a case-by-case basis for each RQ we wish to address. Yet it is the very diversity of methodologies, and research techniques adopted within them, that makes this approach quite unlike the kind of 'paradigm' that Kuhn intended in characterising normal science.

57.12 The Logic of an Extraordinary 'Sort of Science': Science Education as an Aparadigmatic Scientific Field

It was suggested above that perhaps research in science education, and indeed educational research more generally, might fail to look like Kuhn's normal science in part because of the pre-paradigmatic (Gilbert and Watts 1983; Jevons 1973) nature of the field, in which case we might be reassured by Kuhn's acknowledgement that another sort of science will be found in immature fields. Alternatively, we might share Shulman's (1986) view that this is not a matter of immaturity but rather of the nature of what is being studied (e.g. social institutions and processes; often idiosyncratic personal meaning making) which makes science education unlikely to develop a clear paradigm in Kuhn's sense. That is, we might consider science education will remain 'aparadigmatic'.

The next section focuses on these key features of educational research, the complexity and diversity of the phenomena of education and the inherent complications of research with human participants. The argument here is that science education may be a relatively immature field, but that even as it matures it is unlikely to develop a structure that supports an array of relatively discrete sub-fields each with its own disciplinary matrix to support the induction of researchers into a kind of normal science. Rather, given the high level of interconnectedness between different foci of research, all of which should ultimately inform teaching, science education should aspire to be a different 'sort of science' to Kuhnian normal science.

57.12.1 The Ontological Diversity of Educational Phenomena

We have seen that (a) particular research methodologies (strategies) rest upon fundamental assumptions and may cease to make sense as research strategies when those assumptions do not apply; yet (b) this does not restrict the researcher to a limited range of the available methodological choices in any absolute sense. Research design in education then must always (explicitly) take account of ontological and epistemological issues which logically constrain what may be considered sensible methodologies to adopt for particular studies: and as the educational world does not comprise only of entities of one particular ontological status, the starting point for designing research can be quite different for different studies – even within a particular subfield of science education.

That is, there are things of interest to science education researchers that can be tightly defined, fairly objectively identified in the world and counted and measured. These types of things are open to forms of investigation (in particular, research which collects quantitative data to test hypotheses through inferential statistical techniques: experiments, surveys) that would not make sense when the 'objects' of research are instead clearly culturally relative, socially constructed entities. So methodological choices must relate to the nature of *what* one wishes to research (which will have been posited in developing the conceptual framework for the study, cf. Fig. 57.2). Consider the following potential starting points for educational RQ:

- What is the average secondary school science class size in different countries?
- Is teacher subject knowledge or extent of classroom experience more important for successful science teaching?
- How do 11-year-olds understand energy?
- What are 11-year-olds' perceptions of the difficulty of science lessons?
- What is it like to be the only young woman in an undergraduate physics class?

One immediate point to make is that all of these topics involve research into some kind of entity external to the researcher him or herself, so the commitment to undertake research would seem to clearly be an acknowledgement that there is external reality which can be considered the object of (or subject for!) study. This immediately excludes some extreme philosophical positions from usefully informing research. Indeed the commitment to undertake educational research would seem to require the adoption of some key aspects of what is sometimes considered the scientific worldview (Matthews 2009). In particular, embarking on any educational research project would seem to require at least tacit commitment to:

- The existence of some kind of external reality;
- Which has some form of permanence;
- And exhibits certain regularities;
- And which human beings are capable of learning more about.

The posing of particular RQ goes beyond this and sets out certain specific types of entities (schools, classes, teachers, 11-year-olds, understanding, lessons, etc.) as targets or foci of research. That is, even at this stage, certain ontological commitments are revealed. Sometimes these entities are linked to our theoretical perspectives, as when research seeks to investigate Piagetian developmental levels, students' mental models or their alternative conceptions.

Adopting a common epistemology meant to refer to all that we recognise in our world (Crotty 1998) would not seem a sensible starting point. One needs to start from ontology: schools, classes, teaching, understanding, perceptions, mental models, etc. may all be considered to *in some sense* exist in the world, but they are not the same kind of things, and consequently one's epistemological assumptions about them may justifiably differ. So a fairly crude positivistic stance might well be appropriate and effective in seeking to find out the average secondary school science class size in different national contexts, as it is likely to be possible to identify countries and secondary school science classes in ways most observers would find unobjectionable, and determining class size is in principle a simple counting task.

Yet 'successful science teaching' (for example) does not present itself so unproblematically as the subject of investigation: what counts as successful science teaching has shifted over time and is culturally relative, and even in a particular educational context, there will not always be agreement on the appropriate balance between different mooted aims of science teaching – let alone the most suitable indicators that might allow us to make comparisons. Still, even here, in principle we can envisage that researchers might be equipped with an observation schedule of some kind and sent to observe lessons to evaluate the success of science teaching.

Of course no matter how well the data collection and analysis was carried out in such a hypothetical observation study, a reader of the eventual research report would only give credence to the findings to the extent that they accepted the particular conception of 'successful science teaching' informing the design of the observation schedule and were satisfied that the instrument itself could provide valid indications of whether the observed teaching was indeed was indeed 'successful' in *those* terms.

Depending upon how 'successful teaching' is understood, it is entirely feasible that it could even be considered something that could be 'measured' based on quantifiable outcome measures (such as student grades or satisfaction ratings). Where successful teaching is seen simply as teaching that leads to high levels of student examination success, then coming to know where teaching is successful is relatively simple.

Yet, if instead, successful teaching is considered to be about inculcating attitudes and values, about developing relationships, and about supporting maturation, and an interactive process that necessarily involves modifying teaching objectives according to the goals, needs, motivations and personal situations of individual learners, *then* coming to identify and differentiate successful teaching is going to be more challenging, more complex and so inevitably less precise. As always the researcher's epistemology has to be informed by their particular ontological understanding. Where researchers do not agree on the nature of what they are researching (and so in effect are not researching 'the same thing'), they are unlikely to agree on how best to go about their work.

This potentially puts some areas of educational research well outside the type of 'normal science' that Kuhn (1996) characterised as the basis of most work in the natural sciences – adopting canonical definitions and instrumentation widely considered to give valid and reliable results when applied within accepted ranges of application. There is a good deal of creativity and ingenuity at work in the natural sciences, but usually applied within a fairly well-agreed understanding of the nature of what is being researched and the methods appropriate for the job. This is less often the case in educational research. Ziman (1968, p. 115) notes how an 'experienced professional scientist seldom comes into conflict with the referees of his [or her] papers…because…he [or she] has internalized the standards that the referee is trying to enforce, and has already anticipated most reasonable grounds for criticism'. However, in science education, few papers are published without significant revisions required by referees: the experienced professional science education academic may come into conflict with the referees of his or her papers much more regularly than they would wish. This does not reflect on the professionalism of science educators but on the lesser extent of shared commitments and standards for work of those writing and refereeing for particular journals.

57.12.2 Admitting the Subjective Element into Research

Similarly, the classic distinction between the object of research and the (nominally interchangeable) researcher that is an ideal of natural science is often inappropriate in educational research: so where in the natural sciences it might be reported in depersonalised terms that that a sample was ground in a pestle and mortar, in an educational research report, *we* might well report how *we* spoke to a group of students. Eliciting student understanding, for example, is likely to require some kind of co-(re)construction of meaning through interaction between researcher and learner; and when investigating pupils' perceptions of lessons, it is indeed appropriate to consider that meaning is imposed on their experiences by the students themselves rather than being inherent in the activities they take part in.

As suggested above, this does not mean giving up belief in an external reality, but, in this case part of that reality is the experiences of others, and these are not open to being measured or counted like class sizes. Indeed, the best we can hope for is to ask others to represent their (internal mental) experiences in the 'public space' we share (e.g. through talk, drawing, role-play, etc.) and then to look to make sense of these representations in terms of the mental frameworks we have developed through our own experiences in the world (Taber 2014). This type of research *requires* an interpretivist (i.e. subjectivist) approach that acknowledges the difficulties inherent in the task.

Of course as individuals all we ever really know are our own experiences in the world, and there is always something of a leap of faith involved in assuming we share understandings with others. Yet there are differences of degree. We would generally expect that training different observers to reach the same objective 'head count' when surveying class sizes is likely to be less problematic than expecting different interviewers to construct the same model of a learners' understanding of energy or to reach the same understanding of how a female student experiences being the only young woman in an undergraduate physics class.

In the case of understanding energy, we might reasonably expect that such factors as subject knowledge, teaching experience, interviewing experience and expertise and familiarity with prior research could all influence the process of the researcher constructing a model of a learner's understanding, and so the 'results' of the study. In the case of the only woman in the science class, we might consider that the gender of the interviewer could be influential: both in terms of the experiences that the researcher brings to the research as interpretive resources and possibly in terms of the extent to which the female student feels able (or willing) to access and express her experiences and feelings about them.

Such complications undermine the possibility of doing research on people's thinking and experiences that can be as objective as we expect when investigating the resistivity of an alloy or the rate of a chemical reaction. Research always depends on the interpretive resources we bring to the work, *even* in the natural sciences (Keller 1983; Sacks 1995), but in educational research there are many things we want to study where we are unable to eliminate subjectivity, because the interpretive resources relevant to the task (needed to understand another's understanding or to appreciate another's perceptions and experiences) are highly variable among potential researchers. Indeed, we might often expect that the most insightful work is likely to depend upon researchers who have very *particular* knowledge, understanding and experience: such that any objectivist notion that we can substitute another qualified researcher and expect the same result becomes highly questionable.

57.12.3 The Scientific Approach to Educational Research Is to Adopt a Meta-Methodology

The picture painted above is of a field that appropriately draws upon diverse methodologies *because* it deals with a range of different types of research foci, which vary both in how well they are understood and indeed how directly they might be known. The intrinsic variety of educational phenomena and the subsequent diversity in ontological status and epistemological commitments appropriate to particular studies suggest that a mature science education would still lack the kind of constrained disciplinary matrix Kuhn associated with normal science. So science education is not pre-paradigmatic because of its relative youth, but is aparadigmatic because of its need to make principled judgements about methodology in the context of each new research design. Some may refer to this as a mixed methods paradigm, but this seems to pervert the term paradigm to something quite incongruent with its original meaning of a pattern that one can follow to approach a certain kind of problem.

Rather, if we consider methodologies such as experiment, survey and case study as types of strategy that we select between, then science education needs to be informed by a meta-strategy, a meta-methodology that offers guidance on the selection process. We might consider Fig. 57.2 to represent the operation of this meta-strategy, and the principles outlined above – regarding how building a research design needs to be informed by an ontological and epistemological analysis of the basis for the enquiry – indicate the kind of guidance needed. Perhaps, we might see this as aspiring to working within a 'meta-paradigm', not looking to induct researchers into adopting turnkey solutions for well-defined problem areas but preparing them to confidently build research designs bespoke on a principled basis.

If we wish to consider science education as a scientific enterprise despite the need to abandon the aspiration of evolving a research paradigm for the field, we may need to look elsewhere for a demarcation criterion for what counts as science. Popper is well known for his prescription that science should proceed by a process of bold conjecture and seeking refutation (Popper 1934/1959, 1989), and this has been understood as offering such a demarcation criterion. However, in practice, it is well accepted that (i) there is no simple way to determine what counts as a falsification of the theory being tested (rather than, for example, of technical competence or some auxiliary theory of instrumentation) and (ii) in practice crucial experiments only become accepted as such in hindsight, whilst many apparent refutations are quarantined as simply anomalies to be put aside for the moment. However, an alternative perspective on the nature of scientific work, able to distinguish science from pseudoscience, was developed by Lakatos, in his 'methodology of scientific research programmes'.

57.13 Thinking of Research Within Scientific Research Programmes

As suggested above, Kuhn's ideas have been widely criticised although they remain highly influential. In particular, Karl Popper was very critical of the apparently relativist flavour of Kuhn's worked, and there was a high profile debate around aspects of Kuhn's thesis (Lakatos and Musgrove 1970). Popper rejected the 'myth' of the incommensurability between paradigms implied in Kuhn's original formulation of his work (Popper 1994). It was also argued that the account of mature sciences as each consisting of successions of individual paradigms only interrupted by occasional revolutions leading to paradigm shift was an over-generalisation (Machamer et al. 2000) and perhaps was less true in sciences other than physics.

In particular, Imre Lakatos argued that that whilst paradigm-like traditions existed in science and whilst individual scientists would tend to work within such traditions – and indeed often continue to work within them for extended periods of time – it was not unusual for several competing traditions to coexist over considerable periods within the same field of science (Lakatos 1970). Whereas in Kuhn's model this could only happen if one tradition was in the process of being supplanted by its revolutionary successor, for Lakatos it was quite possible for several alternative traditions to continue to be productive and successful in parallel. In Lakatos's terms, these would be considered as co-existing progressive research programmes.

57.13.1 Lakatos's Notion of Scientific Research Programmes

Lakatos's model of scientific research programmes is especially relevant to the theme of this chapter, as it offers a demarcation criterion for what can be considered a scientific tradition that can be applied well beyond the natural sciences. Lakatos's work can be considered to set out the nature of a research programme (RP) and to also offer the criteria upon which such a programme should be considered *scientific*.

A Lakatosian RP shares some features with a Kuhnian paradigm. Both are research traditions that involve an initial establishment providing the basis for considerable later development work, and both require those working within the tradition to make particular commitments. Lakatos (1970) described RP in terms of four key elements in particular that he called the hard core, the protective belt, and the positive and negative heuristics.

The heuristics give guidance on how to develop the RP. The hard core comprises of those key commitments (e.g. ontological commitments), set out at the establishment of the programme, which are essential to the nature of that programme, such that if abandoned the essence of the programme is undermined and in effect the programme has ceased. The protective belt comprises of auxiliary theories that build upon and develop what is established in the hard core, and the positive heuristic sets out how this component is developed (e.g. strategic and methodological aspects of the programme). The auxiliary theories act as 'refutable variants' of the programme in the sense that they are consistent with the hard core, but may be abandoned without risk to the programme as a whole.

Consider, as an example, how modern chemistry has made considerable progress since the establishment of a RP based around modern atomic theory. A core commitment there is that at a submicroscopic level matter can be understood to be quantised and to comprise of discrete entities, particles (or perhaps better, quanticles) which can be considered to have specific properties such that chemical behaviour as observed in the laboratory can be explained by models at the submicroscopic level. Few chemists today will direct research at testing hypotheses that are in direct contradiction with those commitments (i.e. the negative heuristic suggests such work would be counterproductive given the core commitment). Given that commitment, the development of the RP can be furthered by the positive heuristic guiding chemists in how to study the nature and properties of the discrete entities and how to build the theory relating the properties of these entities to macroscopic chemical phenomena.

Within such a programme, specific theoretical ideas will be developed in response to the positive heuristic: so now we tend to distinguish atoms, molecules, ions, etc. Particular models and concepts – a planetary model of the atom, the notion of discrete atomic orbitals, etc. – may be introduced, developed and perhaps sometimes abandoned. This does not threaten the programme itself as long as these refutable variants are consistent with the hard core and no aspect of the hard core itself is put aside. For example, the notion of the atom, and the role it plays within this system, has shifted considerably over time (Taber 2003), but this has not brought into question the core ideas that matter has structure at the submicroscopic level and that the properties of the quanta of matter at this level provide a basis for explaining chemical phenomena: rather such changes are part of the process of considering how best to model and understand the submicroscopic structures that are assumed to exist (i.e. these changes occur *within* and informed *by* the programme).

Lakatos (1970) thought that the notion of RP could apply well beyond the natural sciences – for example, psychoanalysis, Marxism and astrology could all be considered to be RP – but that a *scientific* RP remains 'progressive' in the sense that new theory adds to the protective belt (without simply explaining away difficult results) and empirical work continues to respond to and stimulate theoretical developments.

57.13.2 Research in Science Education as a Scientific Enterprise

Lakatos's work can be considered to offer a form of synthesis of the thesis of Kuhn and the antithesis of Popper. Where Kuhn's descriptive analysis lacked any means to distinguish science from non-science or good science from bad, Lakatos's ideas do offer a basis for deciding when a RP is 'progressive' and so deserves support from scientists. According to Lakatos, several RP may operate in parallel, as long as each offers evidence of being progressive. However, once a programme is clearly degenerating, it should only hold a scientist's loyalty until a new promising alternative appears.

Where Popper offers a prescription that is difficult to operationalise – as all scientific theories are formally refuted on a regular basis and all refutations can be explained away with sufficient imagination – Lakatos offers an analysis that is tolerant of individual failures, so long as the general trend within a programme clearly shows development. Gilbert and Swift (1985) characterised research in the Piagetian traditions and the ACM as co-existing Lakatosian RP in science education. Lakatos's approach not only has the potential to distinguish progressive (and so scientific) programmes from degenerating programmes but also highlights how within a genuine RP there is heuristic guidance for moving the field forward. This can be potentially very valuable to researchers (and new research students), providing research traditions *are conceptualised as* RP (in Lakatos's sense), where the features that offer heuristic value are made explicit.

Given the considerations explored above which lead educational research to draw upon such a multiplicity of methodologies, it seems unlikely that the adoption of an explicit Lakatosian perspective would allow the fields of science education to be reorganised (substantially or simply conceptually) into a number of discrete programmes with each developing the kind of disciplinary matrix Kuhn recognised in the natural science: RP in science education are likely to remain too pluralistic to seem like normal science.

However, a Lakatosian analysis can identify key commitments for particular strands of work, identify clear directions for those strands and make it easier to judge whether they are empirically or theoretically progressive at any point in time. That would certainly be valuable, both in the task of helping those in the field to appreciate the sense in which they are involved in a scientific enterprise – despite the multiplicity of theoretical perspectives and methodologies that will continue to be adopted across, and sometimes within, programmes – and in guiding researchers, journal reviewers and funding agencies in making rational choices regarding where to commit valuable and limited resources.

According to Lakatos, RP are adumbrated at the outset; and it is possible to identify elements of such programmes in science education. One tradition of work in science education (exploring the contingent nature of learning in science building on the tradition of the ACM, drawing initially on a personal constructivist perspective) has been analysed in some detail as a Lakatosian RP (Taber 2006a, 2009b). This analysis identifies a number of hard-core assumptions that were set out in seminal papers that established the programme and which have provided the taken-for-granted commitments of those taking up work in this tradition. The assumptions give rise naturally to a set of initial RQ (i.e. a basis for the positive heuristic) that have been answered (and refined) to differing extents through the development of a range of auxiliary theories and constructs that act as refutable variants of the programme. Arguably (i.e. according to this analysis) this has been a progressive programme, as it has developed its theoretical apparatus in relation to an expanding base of empirical investigations and results.

Despite this, there is clearly something of a shift away from a core aspect of the programme (the strong focus on learning as personal sense making and knowledge construction). This implies that many researchers see this tradition as having less potential for progress than alternative perspectives. This may be so, as undoubtedly as the programme has proceeded the questions to be answered have become more nuanced, and the means of answering those questions have required more effort (e.g. long-term, in-depth study of individuals rather than surveying groups of learners at one point in time).

Without a shared recognition of the heuristics of established RP, decisions about what RQ to follow up will be made by individual graduate students and researchers, with limited moderation by the community. Arguably that tends to be the way of scholarship in the humanities, but it is not how science is organised (Ziman 1968). Individuals will naturally tend to make decisions in their own interest, which is why the apparatus of a scientific enterprise (peer review for publication, funding opportunities, appointment and promotion committees) needs to be well informed about the state of a field to put the right motivations in place for individuals. The mechanisms of RP offer support for that community apparatus. The analysis of the programme of research into the contingent nature of learning in science (Taber 2009b) is certainly not beyond criticism and indeed invites alternative conceptualisations. However, it does show the feasibility of adopting Lakatos's approach as one means of seeking to take seriously the challenge of making science education a scientific enterprise.

57.14 Conclusion

In conclusion, research in science education may never resemble Kuhn's normal science, because of the complexity of educational phenomena, the difficulty of maintaining the integrity of many of those phenomena outside of naturalistic settings and the nature of teachers and learners as individuals each constructing their own understandings of the world and entitled to negotiate the basis on which they might participate in our research. It is likely that many areas of work in science education will continue to draw upon diverse theoretical perspectives and to call upon an eclectic range of methodological tools selected to meet the needs of different specific studies.

However, science education can certainly be a 'sort of science', albeit an 'extraordinary' sort of science: organised to ensure that the adoption of diverse perspectives and methodologies is informed by a meta-methodology and so always based upon rational choices deriving from a sound understanding of the current state of knowledge in the field. Given the nature of educational phenomena, the convergent channelling of Kuhnian paradigms would be too limiting and restrictive. Yet giving researchers completely 'free range' to seek their own problem and develop their own original approaches to solve it – often seen as the path to academic recognition in the humanities – is unlikely to lead to optimum progress in addressing pressing educational problems. Lakatos's notion of RP offers a middle road here, as RP provide guidance to researchers about research priorities and allow the community to take stock of progress, without the blinkers of 'the' paradigm. The way in which educational researchers are commonly trained to develop their projects, with a strong open-ended phase to creatively consider divergent options before making rational and justifiable methodological choices, can be framed (i.e. guided, but not prematurely constrained) within the heuristic guidance of a progressive RP. This would allow the principled development of research designs on a problem-by-problem basis, but guided by the heuristics of an established tradition that the research community considers to be progressive. Arguably, that offers a 'sort of science' that best suits the field of science education.

Keith S. Taber is Reader in Science Education and Chair of the Science, Technology and Mathematics Education Academic Group, in the Faculty of Education at the University of Cambridge (UK). He is the Editor of the journal *Chemistry Education Research and Practice*. After completing a chemistry degree and qualifying as a teacher of chemistry and physics, he taught in schools and further education during which time he undertook part-time research for an M.Sc. (a case study of girls' underrepresentation in physics classes) and Ph.D. (into conceptual progression in chemistry). His main area of research relates to conceptual learning and understanding of aspects of science, including the nature of science. As well as many contributions to research journals and practitioner journals, he has authored/coauthored/edited a number of books, including *Chemical Misconceptions* (Royal Society of Chemistry, 2001); *Science Education for Gifted Learners* (as Editor, Routledge, 2007); *Progressing Science Education* (Springer, 2009); and *Teaching Secondary Chemistry,* 2nd ed (as Editor, Hodder Education, 2012).

Chapter 58
History, Philosophy, and Sociology of Science and Science-Technology-Society Traditions in Science Education: Continuities and Discontinuities

Veli-Matti Vesterinen, María-Antonia Manassero-Mas, and Ángel Vázquez-Alonso

58.1 Introduction

Since the Sputnik crisis in the late 1950s, Western science education has been continuously concerned with the provision of quality training for task-force scientists. Successive innovations did not seem to change the essential aim of traditional school science education, that is, to prepare a small minority of students to become scientists. This approach was plagued with three major omnipresent failures: students' disaffection towards scientific subjects; mythical and distorted image of science conveyed to students, and failure of school science to make students learn science in a meaningful manner, to include the transmission of a view of science which did not account for the broader, sociopolitical sphere of production and application of scientific knowledge (Aikenhead 2006). A humanistic perspective in school science education was thus developed to articulate the range of social, cultural, historical, and political dimensions of science education and to challenge traditional ideas of science as a value-free enterprise (Aikenhead 2006; Donnelly 2004).

The purpose of this chapter is to account for the innovative processes that pioneered the introduction of content related to the history, philosophy, and sociology of science and technology into science education curricula. Our aim is twofold: first, to follow the development of the movements and labels which accompanied these innovative processes, in particular, the science-technology-society

M.R. Matthews (ed.), *International Handbook of Research in History, Philosophy and Science Teaching*, DOI 10.1007/978-94-007-7654-8_58,

(STS) movement, which was born in the 1970s, the ongoing debates surrounding the concept of scientific literacy, introduced in 1950, and the more recent stream of studies on the nature of science and socioscientific issues; second, to show that, beyond labels and names, there are some underlying similarities across all such movements. Similarities are especially important when the continuity of the innovative process with its corresponding movements and ideas is highlighted over the potential differences. A revisit of the history, aims, debates, implementation, and research of the science-technology-society movement is an opportunity to better understand and connect the current proposals for science education (Millar and Osborne 1998).

The scope of the approach adopted to develop such purposes has some specific limitations and rationales. The reflections presented here are restricted to precollege science education where the innovations under scrutiny may have a large impact on citizens' scientific literacy, the public understanding of science, and yet their pedagogical implementation is still scarce in traditional school science curricula. In order to comply with the space limitations, some decisions have also been made regarding the spread of cases covered in our account of continuities and discontinuities under scrutiny. The method selected consists of a qualitative comparison and evaluation of the starting point of the follow-up (STS) and the current situation of humanistic practices in science education. A choice has been made for the latter in favor of the former-mentioned trio of movements (scientific literacy, nature of science, and socioscientific issues). The selection of paradigms draws on the appreciation of both their relevance in the current science education research and their strong relationship to the history, philosophy, and sociology of science tradition, which is the underlying criterion of the search for the (dis)continuities.

Summing up, the account starts from the analysis of the STS movement, as the first relevant implementation of the history, philosophy, and sociology of science tradition in science education, and then it progresses to the selected movements, as the current relevant areas where one can find the history, philosophy, and sociology of science tradition under new forms and contexts. Finally, a conclusion of the account highlights some current debates and outstanding issues in the field.

58.2 Science-Technology-Society (STS) Movement

The science-technology-society (STS) movement emerged from the social upheavals of the 1960s and early 1970s. In the social arena, the Cold War era around the 1950s had enlightened the consciousness of humankind of the likelihood of a global nuclear holocaust, while the environmental movement of 1960s brought to the forefront the increasing damage that industrialization had caused to the environment (e.g., acid rain). During the 1960s several academics and activists such as Lewis Mumford (1967–1970) and Jacques Ellul (1964) as well as consumer activist Ralph Nader (1965) began to express doubts about the presumed benevolence of the new technologies. Because science and engineering sat at the core of those issues, the global concern over these challenges definitively pointed to the responsibilities of scientists and engineers in solving them. In response to this state of affairs, science-technology-society courses were first established in engineering colleges to educate science and engineering students about the societal impact of their work (Cutcliffe 1990). The STS movement in higher education was both an academic field and a social movement, as the scholarly pursuit of science and technology studies was intertwined with the more activist stance of teachers and political organizers (see Cozzens 1993).

Eventually the movement had some effect also on school science education, as it was expected that a better school science education would allow not only scientists and engineers but also general citizens to cope effectively with these challenges. By the 1970s, some researchers became focused on developing materials addressing the complex relationships between science, technology, and society with the purpose of improving school science education. They worked on the idea that science would become more meaningful to students when its relationships with technology were made apparent and how technology, in turn, directed society and the reverse from society to science. A school science education movement called science-technology-society (STS) was born out of these initial efforts for teaching science in the broader context of the mutual relationships between science, technology, and society.

The STS approach involved also a shift from the positivist, non-contextual philosophical stance of traditional science education towards a contextualized, post-positivist view of science (and thus acknowledging the influences of technology, society, culture, ethics, politics, etc.). In the 1960s, the traditional, positivist image of science had been challenged in the academic arena by the historical, philosophical, and sociological analysis of scientists' work, thus providing a new and different image of science. At the time, science education was strictly based on the positivist view of science, whereby knowledge of the natural sciences was kept separate from current history, philosophy, and sociology of science. The emerging epistemological reflection supported by science and technology studies was thus a real challenge to traditional views on curricula and science textbooks. Emerging from the environmental, civil rights, and consumerism movements and preceded by new views of science presented in Thomas Kuhn's (1962) *The Structure of Scientific Revolutions* and post-WWII attention to history, philosophy, and sociology of science in science instruction,[1] Jim Gallagher (1971) proposed that understanding the interrelationships of science, technology, and society should be one of the main goals of school science education. The rationale for STS science education was clearly formulated in his description of a new goal for science education:

> For future citizens in a democratic society, understanding the relationships of science, technology and society may be as important as understanding the concepts and processes of science. (Ibid., p. 337)

---

[1] See, e.g., Conant (1957), Holton et al. (1970), Klopfer (1963), and Klopfer and Watson (1957).

Although the STS movement in higher education began as an academic endeavor for understanding the social issues linked to developments in science and technology, over the course of the decades, it has blended together with sociological and philosophical research about the development of science and technology to constitute an interdisciplinary field of science and technology studies (Sismondo 2010). Building on the constantly developing field of science and technology studies, as well as on research on science, environmental, and citizenship education, STS has remained a major theme in many school science curriculum reforms both in North America and in Europe at least since the publication of Paul Hurd's (1975) article *Science, Technology, and Society: New Goals for Interdisciplinary Science Teaching*. In fact, during the past 40 years, STS has evolved into an umbrella term that includes a wide variety of different views about the connections between science, technology, and environment and approaches to teaching science.[2] According to Glen Aikenhead (1994, 2006), the core conceptual framework for STS in school science education now incorporates two domains of science studies: *internal sociology of science*, interested in the social interactions between scientists and their communal, epistemic, and ontological values, and *external sociology of science*, interested in the interactions of science and scientists with the larger cultural milieu (see Ziman 1984). The emphasis placed on either of these two domains and whether the issues are discussed implicitly or explicitly have varied from project to project and program to program (Aikenhead 1994).

The multifaceted and complex nature of the STS movement has meant that the movement struggled to achieve any kind of internal consolidation. Rather it became the starter for the worldwide development of many slogans (such as socioscientific issues and nature of science), which can be deemed a sign of the developmental power of the STS approach. We argue that these slogans fit the very tenets of STS education, whose complex ecology has been labeled by Aikenhead (2003) in his fortunate title "A Rose by Any Other Name."

58.2.1 Environmental Education and Education for Sustainable Development

From the beginning, the STS movement has had its roots in the planetary fear for nuclear holocaust and in the growing alarm about the environmental impact of science and technology-based artifacts (e.g., weapons and polluting chemicals). The emergence of the environmental crisis in the 1960s documented by works such as Rachel Carson's (1962) *Silent Spring* and Paul Ehrlich's (1968) *The Population Bomb* caused increasing concern from the side of the public about the responsibilities of scientists and citizens, who manage these affairs. This concern had a profound effect also on educational trends. In 1977, the Intergovernmental Conference on Environment Education set the objectives for students' awareness,

---

[2] For more detailed history of the evolution of STS programs, see Aikenhead (2003).

knowledge, attitude, skills, and participation and defined the following goals for environmental education:

> 1. To foster clear awareness of, and concern about, economic, social, political and ecological inter-dependence in urban and rural areas.
> 2. To provide every person with opportunities to acquire the knowledge, values, attitudes, commitment and skills needed to protect and improve the environment.
> 3. To create new patterns of behavior of individuals, groups and society as a whole, towards the environment. (UNESCO 1977, p. 26)

When the term of "sustainable development" was first introduced in the Brundtland Report by the World Commission on Environment and Development (United Nations 1987), it linked the environmental problems to issues of global equity and justice, such as income and resource distribution, poverty alleviation, and gender equality. Gradually, global environmental problems such as climate change and biodiversity reduction also replaced local problems as the main areas of concern and public debate. This reframing of environmentalism had its effects on educational trends; instead of simply referring to environmental education, UNESCO and other international organizations began to promote education for sustainable development (see, e.g., Jones et al. 2010; UNESCO 2005).

The vocabulary of sustainable development also had an effect on scientific practice. Although the political and societal processes preponderantly shaped the sustainable development movement during the late 1980s and early 1990s, by the beginning of the twenty-first century, a new field of sustainability science was emerging (see, e.g., Kates et al. 2001). Promoted by international scientific programs, scientific academies, and independent networks of scientists, sustainability science seeks to understand the fundamental character of interactions between nature, science, technology, and society as well as to "facilitate the move toward a more just and sustainable world as part of the politics of the practical" (Carter 2008, p. 176). Sustainability science is a transdisciplinary approach defined more by the problems it addresses than by the disciplines it employs and it seeks to advance both knowledge and action towards a more sustainable world (Clark 2007). It acknowledges the contextualized, post-positivist view of science promoted by the post-Kuhnian science and technology studies, recognizes that techno-scientific practice cannot stand outside the nature-society system, and seeks to promote social change (Colucci-Gray et al. 2006; Colucci-Gray et al. 2012). Thus, it seeks to involve not only scientists but also "practitioners, and citizens in setting priorities, creating new knowledge, evaluating its possible consequences, and testing it in action" (Friibergh Workshop on Sustainability Science 2000).

With its roots deeply set in the environmental literature, the STS movement shared many common characteristics with environmental education and education for sustainable development. Some science educators even advocated integrating environmental education into more socioscientific issue-driven science-technology-society-environment (STSE) education with the goal of fostering a voice of active citizenship in students (e.g., Hodson 1994, 2003; Pedretti 1997, 2003). Also education for sustainable development shares the goal of preparing the students for civic engagement. This means not only providing the students with knowledge about socioscientific issues and models for informed choices in their everyday life but also building capacity to think critically about what the experts say and participate in the process of developing and testing suitable ideas (see Vare and Scott 2007). As sustainability science is still a relatively new field of study, it is only just beginning to have impact on the research and practice of science education (see, e.g., Carter 2008; Colucci-Gray et al. 2006, 2012).

58.2.2 Socioscientific Issues (SSI) Approach

In the past four decades, STS education has become a relatively complex and diffuse field, which displays a wide variety of approaches and some huge variations in the proportion of STS instruction devoted to societal issues: STS education can range from small text boxes infused into science textbooks to highly specialized courses addressing STS issues (see, e.g., Aikenhead 1994; Pedretti and Nazir 2011). The dissatisfaction with the lack of focused and functional models for STS instruction however was the promoter for new ways forward. One of them is the science instructional proposal called socioscientific issues (SSI).

Promoters of the SSI approach claim that STS education has been missing a coherent developmental or sociological framework and thus “has been relegated to brief mentions in current school science textbooks as well as in science teacher preparation texts” (Zeidler et al. 2005, p. 359). The SSI instruction stresses the factors associated with formal reasoning (argumentation) and the moral principles underlying science-based issues, and it focuses on controversial social issues with conceptual and/or procedural links to science and technology. The socioscientific cases used in SSI instruction are usually open-ended problems, the solutions to which can be informed by scientific principles, theories, and data, though they are not fully determined by scientific or technological considerations (Sadler 2011). Through cases students become involved in social argumentation and reflection aimed at developing cognitive, critical thinking skills and affective moral development.[3]

The STS and SSI movement share the goal of better preparing learners to engage in discussions and decisions related to socially relevant issues associated with science or technology. The SSI movement seems to share similar visions, tenets, and pedagogies with STS, although it may present and argue them differently, so that its promoters claim SSI are “beyond STS” (Zeidler et al. 2005). Much like the

---

[3] Proponents of SSI instruction have suggested various instructional models for utilizing these socioscientific case studies to better achieve these aims (see, e.g., Sadler 2011). For example, Pedretti (2003) suggested a pedagogical model developed from Ratcliffe (1997) and which includes the following stages:

1. Option: Identify alternative courses of action for an issue.
2. Criteria: Develop suitable criteria for comparing alternative actions.
3. Information: Clarify general and scientific knowledge/evidence for criteria.
4. Survey: Evaluate pros/cons of each alternative against criteria selected.
5. Choice: Make a decision based on the analysis undertaken.
6. Review: Evaluate decision-making process identifying feasible improvements.

STSE education, SSI emphasizes informed citizenry and even positions promoting citizenship as the primary goal of science education (Sadler 2011). The advocates of SSI have argued that STS and STSE approaches with similar goals do not give sufficient attention to ethical issues to help the development of the moral and emotional development of students (e.g., Zeidler et al. 2005). SSI is seen as a "broader term that subsumes all that STS has to offer, while also considering the ethical dimensions of science, the moral reasoning of the child, and the emotional development of the student" (Zeidler et al. 2002, p. 344). The advocates of SSI instruction maintain that the STS approach does not appropriately deal with scientific and technological controversies and ethical environmental dilemmas, because it does not exploit the inherent pedagogical power of discourse in socioscientific issues, such as reasoned argumentation, explicit nature of science considerations, as well as emotive, developmental, cultural, or epistemological connections within the issues themselves.

Though promoters of SSI claim that their stress on social, developmental, argumentative, and moral issues is important enough to deserve an epistemological demarcation from the STS approach, the points of similarity between the two approaches seem to surpass the points of distinctiveness. Despite their criticism towards STS, even the advocates of SSI widely acknowledge the parenthood of STS in relation to SSI (e.g., Tal and Kedmi 2006; Zeidler et al. 2005). Besides, because understanding scientific argumentation and justification are fundamental skills in decision making about socioscientific issues, SSI movement is also closely related to the notion of nature of science, discussed in more detail in Sect. 58.4.

58.2.3 Systematizations and Evaluations of STS and SSI

The works of systematization provided by Aikenhead (1994) and Pedretti and Nazir (2011) help to understand the complexity of the STS field. Aikenhead suggested an interesting taxonomy of STS education that classifies the wide variety of STS projects into a spectrum of eight categories, from traditional science to STS science. This taxonomy expresses the relative proportion of the innovative STS elements compared to traditional science content, the way these elements are presented, and the relative weight of STS content in the educational assessment.

1. *Motivation by STS content:* Just a mention of STS content in order to make a lesson more interesting and students are not assessed on the STS content.
2. *Casual infusion of STS content:* A short non-cohesive STS content is attached onto the traditional science topic. Students are superficially assessed on the STS content.
3. *Purposeful infusion of STS content:* A series of short cohesive STS content is systematically integrated into science topics. Part of the students' assessment includes STS content.
4. *Singular discipline through STS content:* STS content organizes and sequences traditional science content. Understanding STS content is assessed, though still less than science content.

5. *Science through STS content:* STS content dictates, organizes, and sequences multidisciplinary science content. Students' understanding of STS content is assessed, though still less than science content.
6. *Science along with STS content:* STS content is the focus; relevant science content enriches learning. Students are assessed equally on the STS and science content.
7. *Infusion of science into STS content:* STS content is the focus and broad scientific principles are mentioned. Students are primarily assessed on STS content and only partially on science content.
8. *STS content:* A major technology or social issue is studied and science content is only mentioned to make links to science. Students are not assessed on pure science content.

Further, Pedretti and Nazir's (2011) review of 40 years of research on STS education identified six currents in STS education: application/design, historical, logical reasoning, value-centered, sociocultural, and socioeconomic currents that explicitly reflect the philosophical, historical, and sociological basis of STS. The first three currents appear to place more emphasis on science-oriented issues, while the other three emphasize socially oriented issues:

1. *The application/design current* focuses on the link between science and technology and solving utilitarian problems through designing new technology or modifying existing technology (technical and inquiry skills). It combines cognitive skills with pragmatic, experiential, creative work in applying scientific knowledge.
2. *The historical current* highlights science as a human endeavor through understanding of the historical and sociocultural embeddedness of scientific ideas and scientists' work. It promotes the intrinsic values of science (exciting, interesting, and necessary pursuit) through affective, creative, and reflexive approaches, where STS and nature of science overlap.
3. *The logical reasoning current* addresses controversial socioscientific issues through the interactions between science, technology, society, and environment. It develops competences on understanding multiple perspectives, critical thinking, and decision making.
4. *The value-centered current* develops moral and ethical values tied to controversial socioscientific issues. Again, it develops understanding multiple perspectives, critical thinking, and decision making on affective and moral issues.
5. *The sociocultural current* addresses science and technology as social institutions to understand its internal organization and external links to politics, economics, and culture.
6. *The socio-ecojustice current* addresses the sociopolitical aspects of science and science education to educate civic responsibility that allows citizens to act on the social and ecological, local, and global problems of the world in search for justice.

By describing value-centered and ecojustice currents, it seems clear that in their review of the STS movement, also Pedretti and Nazir (2011) hold the underlying implicit assumption of a direct parenthood between STS and SSI movements.

After years of researching and teaching through STS materials, Bennett et al. (2007) undertook a systematic evaluation of the effects of context-based and STS approaches in the teaching of secondary science. The study reviews17 experimental studies from eight different countries and the overall findings indicate improvements in attitudes and motivation towards science, while the understanding of scientific concepts and ideas is comparable to that of conventional approaches. Specifically, the review suggests that there is reasonable evidence of the following:

- Students of both genders in classes using a context-based/STS approach held significantly more positive attitudes to science than peers in classes using a traditional approach.
- A context-based/STS approach to teaching science narrowed the gap between boys and girls in their attitudes to science.
- In cases where boys enjoyed the materials significantly more than girls, this was due to the nature of the practical work in the unit. In cases where girls enjoyed context-based materials significantly more than boys, this was because of the nonpractical activities in the unit.

The review also suggests there is some evidence of the following:

- Students in classes using a context-based approach perceived significantly more often a close link between science, technology, and society and showed significantly better conceptual understanding of science than their peers in traditional classes.
- Girls in classes using a context-based/STS approach developed a significantly more positive attitude towards taking a science career compared with boys in these classes.
- Girls in classes using a context-based/STS approach showed equal conceptual understanding of science as male peers in the same classes.
- Lower-ability pupils in classes using a context-based/STS approach held significantly more positive attitudes to science and better conceptual understanding of science than lower-ability pupils in classes using a traditional approach and better attitudes than high-ability peers in the same classes.

Despite the limitations and caveats of the reviewed studies, Bennett and colleagues (2007) acknowledge that the evidence is reliable and valid in supporting the use of contexts as a starting point in science teaching: there are considerable benefits in terms of attitudes to school science and no disadvantages in the development of understanding science.

Sadler (2004) reviewed the literature on SSI to assess its relationship with significant variables of learning scientific literacy, such as skills of informal reasoning and argumentation, conceptualizations of nature of science, evaluation of information, and the development of conceptual understanding of science content. The review by Sadler (2004) does not claim that students will become better informal thinkers, capable of analyzing complex arguments and of developing mature epistemologies of science, by simply being exposed to SSI. On the contrary, the review and further studies (see, e.g., Sadler 2011) consistently suggest that improvements in students' reasoning and argumentation are quite difficult to achieve, and in fact the findings show that reasoning that takes into account scientific evidence is a highly elusive aim as students easily ignore evidence when it is not in accordance with their own claims or previous attitudes. However, SSI studies provide examples of the relative stability of students' ways of argumentation and decision making, though these processes are so deeply rooted in their identity and culture that resist taking into account other elements that go against their own personal points of view. Further, SSI studies can provide an important stimulus for working on the informal reasoning and argumentation skills, the nature of science conceptualizations, the skills of evaluation of information, and the development of conceptual understanding of science content.

58.3 Scientific and Technological Literacy

Since it was first introduced over 50 years ago and especially in the last three decades, scientific literacy has become a central educational objective of science education worldwide (Hurd 1998; Oliver et al. 2001; Dillon 2009). In fact, scientific literacy has developed into an umbrella term covering most aims of science education (DeBoer 2000; Laugksch 2000). In recent years also technological literacy has gained grounds as a similar central tenet for modern technology education (Wonacott 2001). We argue that the STS movement and its derivatives have informed discussion on both scientific literacy and technological literacy. In the following subsections, we summarize the development of these two concepts and their underlining similarities as well as their connections with history, philosophy, and sociology of science, as well as with the STS movement and its derivatives.

58.3.1 Scientific Literacy

The launch of the Sputnik I in 1957 and the following science policy crisis in the United States had a profound effect on science education. The United States as well as countless other nations saw a spur of initiatives aimed at fostering new generations of engineers and scientists, and the number of science-oriented programs mushroomed. The main focus of such programs and initiatives was on training the most gifted students to become scientists and engineers. Although a concern for the public understanding of science dates back at least to the early years of the nineteenth century and had influential proponents such as the educational reformist John Dewey, the concept of scientific literacy as a goal for science education surfaced in the period of reindustrialization after the Second World War. The concept was introduced by Paul Hurd (1958) and Richard McCurdy (1958) at the height of the Sputnik crisis. The interest in the notion of scientific literacy following the Sputnik crisis was focused on improving public understanding and support for the scientific enterprise and industrial programs (see Fitzpatrick 1960; Waterman 1960).

In the 1960s and 1970s, the concept of scientific literacy was being debated, defined, and reconceptualized countless of times.[4] Much like the STS movement, formulations of scientific literacy in the 1960s and 1970s were inspired by new academic research on science and technology studies, which viewed science and technology as socially embedded enterprises, as well as environmental and civil rights movements. Many science educators were also disappointed about the outcomes of a school science education targeted towards a minority of students interested in continuing towards university science and engineering courses rather than developing the capabilities of all students to function as responsible citizens in a world increasingly affected by science and technology. Thus, the definitions of scientific literacy shared many educational goals with the STS movement. For example, Pella and colleagues (1966) suggested that scientific literacy comprises understanding of the basic notions of science as well as understanding the ethics embedded in the scientists' work, the interrelationships of science and society, and the differences between science and technology.

In the late 1970s and 1980s, the advocates of STS education began to dominate the discussion on scientific literacy (DeBoer 2000). The National Science Teachers' Association (NSTA) position statement from 1982 entitled *Science-Technology-Society: Science Education for the 1980s* stated that the goal of school science education was "to develop scientifically literate individuals who understand how science, technology, and society influence one another and who are able to use this knowledge in their everyday decision-making" (NSTA 1982, quoted in Yager 1996, p. 4). Several other countries had similar STS-based programs striving for scientific literacy, such as *Science in Society* (Lewis 1981) and *Science in a Social Context (SISCON)* (Solomon 1983) in the United Kingdom, *Project Leerpakket Ontwikkeling Natuurkunde (PLON)* (see Eijkelhof and Lijnse 1988) in the Netherlands, and *SciencePlus* (Atlantic Science Curriculum Project 1986, 1987, 1988) in Canada. One of the reasons for the growth of emphasis on STS approaches was the recognized failure of science education reforms with a theoretical disciplinary emphasis which were implemented since after the Sputnik crisis (Matthews 1994). The urgency of the need for a change of focus for science education was supported by the publication in 1983 of *A Nation at Risk* (National Commission on Excellence in Education 1983), which documented how, in spite of the efforts following the Sputnik crisis, a vast majority of students were still not interested in science and they learned very little science. This "science literacy crisis" urged for the adoption of more contextual approaches to science education and the goal of scientific literacy for all.

The disenchantment with the results of traditional programs was not the only driving force behind the change. Influenced by civil rights and environmental movements as well as the tradition of liberal education, researchers such as Chen and Novik (1984) and Thomas and Durant (1987) saw scientific literacy as a means to promote more democratic and equal decision making. Scholars still justify the need for a scientifically literate society upon rationales that evoke many of the aims

---

[4] See, for instance, Agin (1974), Daugs (1970), Gabel (1976), Klopfer (1969), O'Hearn (1976), Pella (1967), Pella et al. (1966), and Shen (1975).

of the STS approach, such as socioeconomic development, cultural development, personal autonomy, usefulness for everyday life, decision making, democratic participation in public issues related to science and technology, and ethical responsibility of scientists, technicians, politicians, and citizens (see, e.g., Laugksch 2000). Such reconceptualizations of scientific literacy towards scientific citizenship have laid the ground for new approaches such as STSE and SSI. The influence has been reciprocal, as proponents of STS and its derivatives have been very active in debates on the meaning and purpose of scientific literacy. For example, Zeidler and colleagues (2005) reconceptualize SSI elements of "functional scientific literacy," identifying four areas of pedagogical importance in supporting students' cognitive and moral development: (i) nature of science issues, (ii) classroom discourse issues, (iii) cultural issues, and (iv) care-based issues.

Many advocates of the STS movement and its derivatives go beyond traditional definitions of literacy as knowledge and skills and advocate social action as the highest goal of science education (DeBoer 2000). Much like in science studies, where in the new interdisciplinary fields such as the women's studies researchers began to see themselves as activists working for a change towards more equal and societally conscious science, also in science education some researchers began to advocate a similar activism oriented towards a more equitable and democratic society. These new perspectives on the meaning and purpose of science education have been influenced by a broad array of work from science studies, feminist studies, sociocultural theory, and critical pedagogy. Based on such reflections STS tradition has actively reconceptualized science education as an instrument of social and political engagement and sociopolitical action, which is evident, for example, in the works of Wolff-Michael Roth and Jacques Désautels (2002) and Wildson dos Santos (2008).

58.3.2 Scientific Literacy as Literacy for All

Much like what we saw with the STS movement, differences that appear between the various definitions of scientific literacy proposed by various specialists and the level of substantive disagreement about its content seem to highlight the complexity of concept (Bybee 1997; Gil and Vilches 2001; Manassero and Vázquez 2001). For example, various stakeholders interpret the word "literacy" in numerous different ways. In science education research, scientific literacy is defined from a variety of perspectives: as a motto, which covers a broad international movement (Aikenhead 2003); as a metaphor that expresses the aims and objectives of science education (Bybee 1997); and as a cultural myth that indicates the ideal to pursue (Shamos 1995).

To analyze the wide variety of meanings of scientific literacy, Roberts (2007) suggests a heuristic tool featuring two extreme positions, which he calls Vision I and Vision II. Vision I corresponds to the literacy within science, that is, the decontextualized products (facts, laws, theories, etc.) and processes of science. According to Vision I school science should give pupils knowledge and skills to approach situations as a professional scientist would. Vision II refers to literacy that a student would be likely to require as a citizen acting in situations outside the scientific world, or not entirely belonging to science, although clearly related to it. In Vision II the aim of the education is enabling students to approach situations as citizens who are well informed about science. Proponents of the STS movement and its derivatives have usually been positioned more towards Vision II of science education (see, e.g., Zeidler et al. 2005). Having these two poles of the heuristic tool in mind helps to analyze the relative proportion of these possibly conflicting goals in various definitions and descriptions of scientific literacy (much in a similar manner as the Aikenhead's STS categories help to analyze the amount of STS content in a project).

Paralleling the aims of general literacy (reading and writing), scientific literacy has since the science literacy crisis of the 1980s been increasingly associated with its complement of being a literacy "for all," especially in the school years before choosing a major. The concept of scientific literacy has thus been increasingly associated with its complement "science for all," assuming they are inseparable, but without clearly specifying what they mean, thus creating some confusion and debate. Tippins et al. (1999) argue that scientific literacy and science for all are potentially two contradictory concepts; on the one hand, the idea of science for all requires that no one is excluded from science education, thus creating a need for inclusive and meaningful school science, which has relevance to all students (see Vázquez et al. 2005; Vázquez and Manassero 2007); on the other hand, scientific literacy appears to be based on a certain set of knowledge, skills, and attitudes that students must seek, for example, the contents of the *Benchmarks* (American Association for the Advancement of Science 1993) or the *NSE Standards* (National Research Council 1996). It seems that the goal of science for all requires different contents of school science for diverse learners, while scientific literacy implies the idea that all science programs must meet the same set of criteria. Students can be taught notions of science apparently needed to acquire knowledge and skills required for scientific literacy, but it may be that learning such knowledge and skills will prove to be uninteresting and of little value to the students (Manassero and Vázquez 2001). Thus, there seems to be an obvious tension between scientific literacy and science for all. This tension is at the core of the debates about the goals of science education and, in general, of all basic education that must be common and inclusive (Acevedo et al. 2003; Tippins et al. 1999) and of the demands of higher education and the benchmarking needs for preparation for a career as a scientist (Abd-El-Khalick 2012).

From recent international research in science education and current educational reform initiatives, the progressive visions of scientific literacy encompass broad conceptual frameworks that entail basic knowledge of science (scientific facts, laws, and theories) and increased emphasis on the knowledge about science, that is, understanding about the processes and methods used to develop such knowledge (scientific inquiry) as well as the history, sociology, and epistemology of scientific knowledge (nature of science). In particular, students are expected to develop some specific scientific knowledge, skills, and attitudes, which involve understanding science as a "way of knowing" (absolutely necessary, if informed decisions are to be made), decision making on scientifically based personal and societal issues that increasingly confront the students, as well as the development of a commitment to the moral and ethical dimensions of science education that include the students' social and character development. Such decisions represent a functional degree of scientific literacy as they necessarily involve careful evaluation of scientific claims by discerning connections among evidence, inferences, and conclusions through the ability to analyze, synthesize, and evaluate information. A degree of scientific literacy also entails practice and experience in developing scientific attitudes such as skepticism, open-mindedness, critical thinking, recognizing multiple forms of inquiry, accepting ambiguity, searching for data-driven knowledge, dealing sensibly with moral reasoning and ethical issues, and understanding the connections that are inherent among socioscientific issues (Zeidler 2001).

Since scientific literacy is closely linked to social, cultural, and ideological aims of education, it is virtually impossible to establish a complete model of school science curricula to better achieve it. Although the aims, purposes, and objectives might be widely shared, it might be unrealistic to expect all students to achieve the same specific objectives. As different societies and social groups interact differently with science and technology, the standard-based curricula should consider only general references that should be developed in the classroom through specific contexts. In practice, scientific literacy can be grasped in different ways and with different levels of complexity to adapt to different contexts and students. However, this contextualization should keep the general framework and the principle of equity. We maintain that the paradigm of science-technology-society (STS) is best able to guide the selection of basic content that is relevant and useful for all students and also by providing us with methodological guidelines that contextualize into practice this important educational innovation (see Acevedo et al. 2003).

58.3.3 Technological Literacy

Traditional technology education was based on the industrial model of technology, which during the past decades and in the new era of information technology became apparently outdated. In a technologically mediated world, technological literacy requires understanding about the impact of new and emerging technologies on society and the environment (Dakers 2006). The notion of technological literacy has been established as the central tenet for modern technology education (Wonacott 2001).

Much like scientific literacy calls for a science education for all and focuses on the nature of science, processes of scientific research, and interaction of science and society, technological literacy calls for a technology education for all and focuses on the nature of technology, process of technological design, and interaction of technology and society (see, e.g., ITEA 2000). Again, much like with scientific literacy, the goal of technology education is increasingly seen in promoting more democratic and equal decision-making processes and social action. One of the most comprehensive classifications of the goals of technology education was the model based on functional competencies described by Layton (1993). The functional competencies included:

1. *Technological awareness (receiver competence):* The ability to recognize and acknowledge the possibilities of technology in use
2. *Technological application (user competence):* The ability to use technology
3. *Technological capability (maker competence):* The ability to design and make artifacts
4. *Technological impact assessment (monitoring competence):* The ability to assess the personal and social implications of use of technologies
5. *Technological consciousness (paradigmatic competence):* The ability to work within a "mental set," defining what constitutes a problem, circumscribes what counts as a solution, and prescribes the criteria which technological activity is to be evaluated
6. *Technological evaluation (critic competence):* The ability to judge the worth of technological development and to step outside the "mental set" to evaluate it

In the last 20 years, the focus of technology education has moved from providing vocational skills in technology to developing critical competencies in multiple techno-literacies, which include critical computer literacy and critical multimedia literacy (Kahn and Kellner 2006). Change of focus in aims of technology education resembles the change from Vision I science education to Vision II science education (see Roberts 2007). With such new goal for technological literacy, learning and teaching technology becomes a dialogue; the teacher and students form a community with no right or wrong answers, only more or less informed interpretations (Dakers 2006).

Much like with the definitions of scientific literacy, academic science-technology-society programs have influenced definitions of technological literacy. In the 1980s, researchers in science and technology studies turned their attention to technology. MacKenzie and Wajcman's (1985) *Social Shaping of Technology* and Bijker et al. (1987) *The Social Construction of Technological Systems* paved the way for sociological accounts of technological change, much like the turn to naturalistic accounts of scientific progress revolutionized the view of scientific practice more than a decade before. Emerging sociology of technology shared theoretical and methodological lines with sociology of science and supported the unity among science and technology studies.

There are also some common misconceptions concerning technology, for instance, that science is exogenous to technology. The view that scientific discovery leads to technological innovation is so strong that it is often forgotten that there is a notable reverse flow from technology to science. Technological innovations are not just products of science – they have enormous influence also on the process of science (Stokes 1997). In fact, technology plays a huge role in the process of creating scientific knowledge as scientists create all instruments, experimental settings, and even objects of research. Direct observations of scientific phenomena usually happen at a level unattainable to our perception and phenomena are accessed through the window of technology, with instruments especially designed to refine our current scientific models (Hacking 1983). The way scientific research is done has always been and still is transformed by technological development of instrumentation (Ziman 1984). Science and technology education should take cognizance of the essential interdependence of science and technology (see, e.g., Tala 2009). We argue that instead of speaking simply about "scientific literacy" and "technological literacy," we should rather use the notion "scientific and technological literacy," which better acknowledges this bidirectional relation between science and technology (see, e.g., Fourez 1997; Holbrook 1998).

58.4 Nature of Science (NOS)

In developing scientific and technological literacy, the meta-knowledge that arises from the interdisciplinary reflections on science and technology plays an integral part. One of the central elements of STS and scientific literacy is to understand what science is, how it works, and how scientists operate. As science studies have discussed these issues and should inform teaching practice, there is a vast and complex literature on history, philosophy, and sociology of science in science education (for an overview, see, e.g., Hodson 2008, 2009). Within science education, suitable educational answers to these questions have been described by various characterizations of nature of science (NOS). In the research literature NOS is gaining ground as the most common representation of the essentials of informed and updated picture of science. NOS issues involve the most relevant features of history, philosophy, and sociology of science: what science is, how it produces valid knowledge, how it relates to technology and society, who are the scientists, how they work and relate among each other, and so on (e.g., McComas et al. 1998). The aim of producing an authentic image of science was also an important pursuit of STS approach, and as a crucial element of scientific literacy, NOS is now widely recognized to be a key concept in the curricular aims of science education all over the world.[5]

School science curricula are often filled with simplistic visions that produce mythical and deformed views of science, as, for instance, the absolutism of scientific knowledge and the stereotypical step-by-step approach of the scientific method, which hinder learning appropriate views of science and appropriate teaching of NOS in the classroom. The very question of NOS and science education arises from the inadequate images of science that school curricula and textbooks convey to students (see, e.g., Vesterinen et al. 2009; 2011). This concern was early assumed by STS movement as crucial, though modest educational aim, and today it is incorporated within definitions of scientific literacy as "learning about science" (see, e.g.,

---

[5] See, for instance, Adúriz-Bravo and Izquierdo-Aymerich (2009), Hodson (2003), Matthews (2004), and McComas and Olson (1998).

Abd-El-Khalick 2012; Hodson 2009). This new aim goes beyond learning science: students should learn some basic epistemological, historical, and sociological traits of science and scientists in order to better understand how science works in the current world.

Understanding how science works is an important key for appraising scientific claims, evaluating scientific arguments, and forming a personal opinion on socioscientific issues. NOS knowledge needed for addressing socioscientific issues includes things such as the ability to distinguish between science-in-the-making, where uncertainty is to be expected, and ready-made science, on which we can rely, and the ability to recognize how sociocultural, political, economic, and religious factors can impact science, as well as the reverse (Kolstø 2001). Zeidler and colleagues (2005) even describe NOS as one of the four areas of pedagogical importance to the teaching of socioscientific issues within a curriculum striving towards scientific literacy.

58.4.1 Systematizations and Evaluations of NOS

NOS is a very complex concept, partly because it evolves and changes as our understanding of science and science itself evolves and changes. NOS brings together a variety of aspects coming from different disciplines, such as history, philosophy, sociology, and psychology of science (Vázquez et al. 2001). Thus, NOS is meta-knowledge arising from the interdisciplinary reflections on science, which have been conducted by specialists from a multitude of disciplines (Vázquez et al. 2004). In fact, NOS might present so many faces that Rudolph (2000) even contends that a single NOS does not exist at all.

Although there might not be a general agreement on the exact definition of NOS, there seems to be some sort of consensus regarding the central features of NOS that should be covered in science education (see, e.g., Lederman 2007; Niaz 2008). On the whole, the educational consensus on NOS refers to basic and relevant NOS features while keeping them highly uncontroversial: what is science; the methods science uses to construct, develop, validate, and disseminate the knowledge it produces; the features, activities, and values of the scientific community; and the internal and external links of science, such as the links between science, technology, and society. The most striking aspect of the consensual NOS features, which in turn provides further evidence in support to the teaching of NOS in schools, is the strong similarity among the different lists that researchers have proposed.[6]

In spite of consensus, there remains some divergence about the relative weight the consensual aspects should have on school science. Looking at the current mainstream NOS literature, NOS is mainly depicted as epistemology or philosophy of science, while the relationships with technology and society are much less taken

---

[6] See, for instance, Abd-El-Khalick (2012), Lederman (2007), McComas and Olson (1998), and Osborne et al. (2003).

into consideration. However, an in-depth reading of the mainstream current research on NOS also evidences that broader STS social relationships, especially those referred to the works and status of the scientific community, are also recognized as part of the NOS field.[7] For example, the descriptions of the central features of NOS include both philosophical perspectives on science and characteristics inherent to scientific knowledge (epistemology of science), such as the empirical and tentative nature of scientific knowledge and the key distinction between theories and laws, as well as the sociological perspectives on scientific practice, such as social dimensions and cultural embeddedness of science.[8] Even though some NOS research tends to reduce NOS to a few epistemological aspects, the core conceptual framework of STS seems compatible with broader consensual NOS issues, whose enlarged frame embraces much more relevant features and keeps NOS more faithful to its multifaceted and contentious character (Matthews 2012).

The decades of research on the NOS conceptions of students and teachers allow Lederman (1992) to affirm consistently that students and teachers do not have appropriate knowledge about NOS. Research in science education to improve learning and teaching about NOS has largely documented the difficulties associated with developing sound understanding of NOS. The complexity of this task is due to the amount of interacting factors involved that prevent, limit, or facilitate teaching NOS and clarifying the effectiveness of different methods. In spite of the difficulties, it seems that some necessary, though not sufficient, conditions are curriculum development (planning, developing, and assessing) and the effectiveness of teaching in the classroom. The several contexts for developing and teaching NOS used in these studies express the complementary importance of domain-general NOS features and the diversity of domain-specific implementations. Some domain-specific contexts involved in the studies that test the effectiveness of teaching are the following: practical activities (inquiry processes), specific courses on methods and philosophy of science and technology, history of science and technology, techno-scientific issues of social interest, and impregnation of traditional science and technology with NOS contents.

An important part of implementing these contexts is the verification of the effectiveness of a variety of NOS teaching methods, which can be summarized in two basic approaches (Abd-el-Khalick 2012; Lederman 2007):

1. *Implicit teaching:* NOS contents are implicitly inserted into classroom activities, without any further planning or discussion of them, which presumably leads to NOS learning as an automatic by-product of activities.
2. *Explicit instruction:* NOS contents are made explicit in the educational activity (curricular planning and meaningful objectives, content, and evaluation), and clear reflective applications are developed in the classroom through argumentation, development of metacognition, or conceptual change.

---

[7] See, for instance, Abd-el-Khalick (2012), Leach et al. (2003), Lederman (2007), Osborne et al. (2003), Sandoval (2005), Tsai and Liu (2005), and Vesterinen et al. (2011).

[8] See, for instance, Abd-El-Khalick (2012), Lederman et al. (2002), and Osborne et al. (2003).

The review of literature on the relative impact of implicit versus explicit approaches towards addressing NOS issues shows that implicit approaches are less effective than explicit reflective approaches (Abd-El-Khalick and Lederman 2000). As an explicit and context-based approach for teaching NOS, the history, sociology, and philosophy of science form the natural setting for discussion, because each of them shows how to build scientific knowledge in the social and historical context (Hodson 2008; Lederman 2007). A specific pedagogical attention to the epistemic and social aspects of inquiry through discursive argumentation activities is also stressed in a recent review of curricular interventions on changing students' NOS conceptions (Deng et al. 2011).

58.4.2 From NOS to NOST

As mentioned earlier, some scholars tend to reduce NOS features especially to philosophical values and epistemological characteristics of scientific knowledge. Although reductionist definitions of NOS could also improve skills, such as distinguishing between good science and bad science as well as the capacity to read and evaluate scientific texts, there is a need for a larger set of skills and attitudes to address science and technology-related issues in a critical way and to reach informed decisions on socioscientific issues impacting our society and the environment. From this wider perspective, it can be argued that there is a need also for a broader conception of NOS encompassing a wider variety of features, such as how science builds, validates, disseminates, and develops knowledge; what values are involved in scientific activities; which are the characteristics of the scientific community; and how science is related to society and culture.[9] Further, even though the roles of social and societal dimensions of science are sometimes cited as central features of NOS, the role of technology is often neglected in most definitions. In order to produce an authentic image of science, there is clearly a need to embrace both the science and technology as complementary aspects of contemporary scientific activity and emphasize the techno-science dimensions of NOS (see, e.g., Tala 2009; Vesterinen et al. 2011).

To tackle these issues, the rich history of the STS movement provides a variety of pluralistic educational models of science and technology, which help students and teachers to answer questions or to critically assess coexisting controversial views, rather than pursuing indoctrination into a particular model of science and technology such as memorizing a couple of uncontroversial tenets about NOS. Even though certain teachers might favor a misbalanced or limited presentation of science, either empiricist or relativist, or avoid questioning on a debatable issue (see Clough 2007), a more pluralistic model which includes several coexisting views of science and technology and their interactions should be provided (see

---

[9] See, for instance, Acevedo (2008), Matthews (2012), Vázquez et al. (2004), and Vesterinen et al. (2011).

Matthews 2012). To cover the enormous complexity of techno-scientific systems in contemporary societies, we argue that the concept of NOS should be extended as nature of science and technology (NOST), which would take into better consideration issues such as the ethical and democratic values of science and technology and solving social and ecological problems through human agency and action.

The former reflection does not imply that students become historians, philosophers, or sociologists of science and technology. Rather, understanding NOST through science education has to be developmentally adapted to students and contexts, to attain modest and realistic goals (see Abd-El-Khalick 2012; Matthews 1998). For instance, the students should acknowledge the history of science, the role of the scientific community in the production of scientific knowledge, and some basic features of the philosophy of science, to become competent in informal reasoning on issues at the coupling of science, society, technology, affectivity, ethics, moral development, and civic participation.

58.5 Conclusion

This paper aimed to reflect on the course of implementation of innovative humanistic approaches to school science starting from the leading role of the science-technology-society (STS) movement ahead. It aimed to set up and to follow up the continuities and discontinuities of this evolution through the new emergent currents for teaching and learning science that become associated with the history, philosophy, and sociology of science. Although there are several other slogans and labels for this kind of humanistic science education (see, e.g., Aikenhead 2006), the chosen approaches have been selected because of their most notable influence on school science education.

The leading role of the STS movement is the cornerstone of what has been known as humanistic science education and its many derivatives, such as discussion of socioscientific issues (SSI) and nature of science (NOS). In fact, the six STS currents identified by Pedretti and Nazir (2011) draw quite explicitly on the thesis of the global resemblance among STS, SSI, and NOS approaches. Although it can be argued that STS and the aforementioned research lines (SSI and NOS) are different educational trends, it seems quite obvious too that they all share the importance of developing broad key competencies for scientific and technological literacy and are deeply rooted in the history, philosophy, and sociology of science.

The early distinction between the two fields of science and technology studies provides the inspiration for looking at the clear and direct evolution and connection of STS and NOS approaches. The “science and technology studies” interested in understanding scientific and technological practice and discourse and the “science-technology-society studies” interested in understanding social issues linked to scientific and technological development at some point appeared to be separate projects (see Sismondo 2010). Based on this division, STS and its direct derivates such as STSE and SSI were mainly inspired by research on social issues linked to science and technology. Conversely, NOS was mainly influenced by science and technology studies focused on scientific practice. These two broad fields of science and technology studies have in recent decades blended together. As part of the clearer current understanding on the global interrelatedness of science-technology-society issues, also STS, SSI, and NOS are now being perceived as related and overlapping constructs: STS and SSI approaches include the understanding of NOS features as a central educational objective, and conversely, socioscientific issues are used as an educational context to teach NOS features.

Alternatively it can be argued that if STS and the aforementioned research lines are dominated by the overall continuities among them to such a degree, then they should not deserve different labels. The amount of literature accumulated on each of these areas and the definitions made by their promoters on their unique characteristics and demarcation criteria project an interested image of epistemological differentiation rather than continuity from the original STS (i.e., the promoters of SSI insist on the moral and character education of SSI as a key differential trait from STS). A balanced position on humanistic approaches to science education should recognize the continuities as well as their progress along the differential discontinuities. In spite of the continuities, the rising of the different labels from the original multiform STS proposals has certainly contributed to deeper progress of research by reframing more specific educational problems, such as literacy and scientific competence beyond process skills, contribution to moral education beyond general impact on society, argumentation on facts and evidences beyond critical thinking, and understanding specific consensual issues on NOS beyond generic understanding about science, just to mention some of the most significant milestones of this progress.

The proponents of STS and its more recent derivates have also been active in redefining scientific literacy, which has developed into an umbrella term covering most aims of science education (e.g., DeBoer 2000; Laugksch 2000). Currently all the aforementioned approaches fit under the banner of scientific and technological literacy. For example, Hodson (2009) presents a conceptualization of scientific and technological literacy aligning with the STS efforts to innovate science education by adequately dealing with many challenges of a scientifically and technologically mediated world. Inspired by description of functional competencies of technology by Layton (1993) and competency model of science literacy by Gräber and colleagues (2002), Hodson (2009, p. 15) describes four major elements of scientific and technological literacy as a goal for school science education:

- *Learning science and technology* – acquiring and developing conceptual and theoretical knowledge in science and technology and gaining familiarity with a range of technologies
- *Learning about science and technology* – developing an understanding of the nature, methods, and language of science and technology; appreciation of the history and development of science and technology; awareness of the interactions among science, technology, society, and environment; and sensitivity to the personal, social, economic, environmental, and ethical implications of technologies

- *Doing science and technology* – engaging in and developing expertise in scientific inquiry and problem solving as well as developing competence in tackling "real-world" technological tasks and problems
- *Engaging in sociopolitical action* – acquiring (through guided participation) the capacity and commitment to take appropriate, responsible, and effective action on science-/technology-related matters of social, economic, environmental, and moral-ethical concern and the willingness to undertake roles and responsibilities in shaping public policy related to scientific and technological developments at local, regional, national, and/or global levels

The STS movement has been instrumental in setting up a basic shift of understanding of the term scientific literacy towards scientific citizenship and its association with science for all. New conceptualizations of scientific and technological literacy, such as the one presented above, demand that science teaching can no longer be bound to the transmission of traditional scientific and technological knowledge aimed to prepare scientists and engineers, which has been the indisputable and perennial aim of science education all over the world. Science education should go beyond science facts and laws to get a more holistic and useful approach for citizens, most of whom do become neither scientists nor science workers. Literacy for all assumed the original concern of STS movement to include all students into the culture of science and technology, no matter the minority they belong to, through improving their interest and attitudes to science, in order for them to become better citizens and better prepared to participate in society. It is argued that science education simply cannot stick to the scientific knowledge and the process of producing such knowledge, but the goals and capacities to be developed should have a more holistic approach and a genuine social relevance, including ethical and democratic values (Holbrook 1998). Thus, the STS proposals have also evolved to improve their contribution to science education, not just drawn to acknowledge the pitfalls but also to attain new educational challenges (such as scientific and technological literacy for all) in new educational settings and societal contexts (information, communication, and risk societies).

The STS movement and its conceptual variations originated from and have been influenced by interdisciplinary science and technology studies in higher education as well as environmental and civil rights movements. These roots are all but forgotten in the current humanistic perspectives such as NOS and SSI. New research on history, philosophy, and sociology of science still informs research and practices on science education, and the capacity and commitment to engage in sociopolitical action on matters of social and environmental concern are increasingly seen as the key competencies developed through science education (see, e.g., Hodson 2009). The humanistic perspective challenges traditional science education in at least four ways:

1. *The switch of focus from "science for scientists" to "science for all" (from Vision I to Vision II):* Science education must be inclusive, that is, committed to the aim that all students (not only those aiming to be scientists) should understand contents "of" science (concepts) and concepts "about" science (NOS). Science

education should enculturate students into their local, national, and global communities, rather than into scientific disciplines.

2. *Focus on the relevance of learning:* To achieve the education that excludes no one and to produce significant learning that is useful for students' everyday life, science education is expected to be interesting and relevant. Science education should thus be context-driven and student-centered.
3. *Focus on the additional key competencies in science and technology:* The focus of science education cannot be solely on knowledge, skills and characteristics demanded of scientists, but rather on the knowledge, skills and characteristics demanded of general citizens. Such competencies include, but are not limited to, the following skills: high order cognitive abilities (argumentation, analyzing, synthesizing and evaluating information), informed decision making, communicating and discussing openly ideas and facts, and designing and developing projects.
4. *Focus on the history, philosophy, and sociology of science contents:* For example, the task of making informed decisions on socioscientific issues demands some knowledge "about" science. The history, philosophy, and sociology of science can be used either as core curriculum content or as the context that surrounds disciplinary learning activities in science.

The current concern for effective and evidence-based teaching and learning is perhaps the most practical drive for connecting history, philosophy, and sociology of science content and curricular developments in classrooms. Although the number of evaluative studies is quite scarce within the STS movement proper, as the study of Bennett and colleagues (2007) evidences, the evaluative studies available on scientific literacy (e.g., OECD's PISA project), NOS (e.g., Lederman 2007), or SSI (e.g., Sadler 2011) are essential to broaden our view. Evaluations of humanistic approaches in science education point out that success in this field requires some basic conditions. Most of the current literature is unanimous in acknowledging that developmental, explicit, and reflective teaching is a necessary condition to successful learning, which in turn must be supported by detailed curricular planning.[10] These plans should involve explicit objectives, activities, and assessment and many reflective activities within classroom implementation where students are given opportunities to consider, discuss, construct arguments, and consolidate their understandings on broad features of science.

To meet the wide variability of demands from primary education to college education students, curricular planning should also acknowledge a developmental perspective. For instance, the controversial and interrelated character of the history, philosophy, and sociology of science issues suggests that decisions on sequencing issues across grades are not obvious. In spite of this, the developmental perspective has been scarcely discussed in NOS and SSI research, perhaps supposing implicitly that teachers are able to adequately cope with it while transposing their practical

---

[10] See Abd-el-Khalick (2012), Bennett et al. (2007), Lederman (2007), Matthews (2012), Sadler (2011), and Vesterinen and Aksela (2012).

knowledge in science teaching to teach humanistic content. Thus, the previous prescriptions and conditions to achieve effective teaching and learning need to be complemented with accurate developmental sequencing of issues and activities (see, e.g., Abd-el-Khalick 2012).

Summing up, this chapter traces a journey through humanistic perspectives in science education from STS and scientific literacy movements to the current SSI and NOS movements, influenced by and influencing the various conceptualizations and reconceptualizations of scientific and technological literacy. Along this journey some might perceive a kind of reductionism, as the wide variety of historical, philosophical, or sociological controversial issues in science and technology education, which are typical of humanistic approaches (see Aikenhead and Ryan 1992), have been progressively focused on a much more specific and limited list of features. For instance, much of the research and teaching experiences on SSI issues focuses on current social controversies, thus relegating to a corner the many past historical controversies, which are also essential to sound training in science. Further, much research and teaching on NOS focus on seven issues elaborated by Lederman and his colleagues (e.g., Lederman 1992, Lederman et al. 2002), thus relegating out of the scope of scientific literacy wider visions of NOS and many NOS issues. This reductionism could help researchers to better demarcate the field of study, while in education this effort might be justified on the basis of meeting the students' needs, for example, in the selection and choice of curriculum issues that could better fit the diverse populations of students (simpler pedagogical transposition, best modest goals, students' age and interests, etc.). In the long run, however, this reduction somewhat weakens the richness of the original historical, philosophical, or sociological roots of humanistic approaches to science education, and claims for overcoming this reductionist state of affairs have already been put forward (see Matthews 2012).

Coinciding with the planned school science reforms, developed and implemented in many countries over recent years, the international debate over humanistic perspectives in higher education has also been revitalized. According to Sjöström (2008), there is a need for taking into account the societal and ethical dimensions of scientific practice and taking part in public discussion about the discipline by practicing scientists; in turn, this involves a need for more emphasis on Vision II-like approaches also in the education of future scientists. Krageskov Eriksen (2002) argues that with a humanistic perspective guiding the educational planning, scientists and engineers capable of critically considering the premises of the system, "the rules of the game" – not just skilled players – could be the intent of higher education. She argues for the need of three kinds of knowledge in tertiary science education: (1) "ontological" scientific knowledge, i.e., scientific facts and theories; (2) "epistemological" knowledge, i.e., philosophical and sociological perspectives on the scientific practice; and (3) "ethical" knowledge, i.e., reflection on the role of science and science education in society. The humanistic perspective originating from the engineering colleges and academic science-technology-society programs seems to be returning back to colleges and universities via the STS school science movement.

Veli-Matti Vesterinen is researcher and teacher educator with a Ph.D. degree in chemistry education from the University of Helsinki (Finland). From 2007 he has taught on several pre- and in-service teacher education courses at the Department of Chemistry and at the Department of Teacher Education. He has authored several papers discussing nature of science and chemistry teacher education (both in Finnish and in English). The papers have been published in books and scientific journals such as *Chemistry Education Research and Practice* and *Science & Education*. He is also active in the field of informal science education. He is a cofounder of MyScience and Luova, popular science websites for teens, as well as a cofounder and editor-in-chief of the *European Journal of Young Scientists and Engineers*. For his work on popularizing science, he was one of the recipients of Finnish State Award for Public Information in 2009. Drawing insights from science and technology studies and the emerging field of philosophy of chemistry, his main research interests include scientific and technological literacy, nature of science and technology, education for sustainability, and the aims of science education.

María-Antonia Manassero-Mas is professor of social psychology in the Department of Psychology at the University of the Balearic Islands (Spain). She earned a special Degree Award in Psychology (University of Barcelona) and special Ph.D. award in Psychology (University of the Balearic Islands). Her research developed through peer-evaluated research projects focused on psychosocial processes and social psychology of science, science education, students' attitudes to science, science achievement, science-technology-society, gender differences, scientific literacy, and nature of science. She is author or coauthor of science education books (in Spanish) *Causal Attribution Applied to Educational Orientation (1995); Views on Science, Technology and Society (1998); Assessment of Science, Technology and*

Society (2001); Teaching Stress and Burnout (2003); Secondary Students' Interests on Science and Technology Curriculum (2007); The Relevance of Science Education (2007); and Science, Technology and Society in Latin America (2010), as well as many other book chapters, papers (e.g., Spanish Secondary-School Science Teachers' Beliefs About Science-Technology-Society (STS) Issues, Science & Education, 2012), and communications to congresses.

Ángel Vázquez-Alonso is educational inspector of the Balearic Islands (BI) Government and honorary researcher at the BI University (Spain), where he has taught physics, research methods, curriculum development, and educational evaluation and trained high-school teachers in the Department of Physics and Department of Education. He earned three degrees in Physics, Chemistry, and Education, and a Ph.D. on Educational Sciences, taught high-school Physics, and directed the BI Educational Quality and Evaluation Institute. His research interests have developed through peer-evaluated research projects on students' conceptions and attitudes to science, science achievement, science-technology-society, gender differences, scientific literacy, and nature of science. He is author, editor, or coauthor of some books (in Spanish) and curricular materials: *Clay* (1997); *Views on Science, Technology and Society* (1998); *Assessment of Science, Technology and Society* (2001); *Teachers: Commitment for Education* (2003); *Secondary Students' Interests on Science and Technology Curriculum* (2007); *The Relevance of Science Education* (2007); *Technology Education* (2010); and *Science, Technology and Society in Latin America* (2010), as well as book chapters, papers (e.g., Science Teachers' Thinking About the Nature of Science, *Research in Science Education*, 2012), and communications to congresses.

Chapter 59

Cultural Studies in Science Education: Philosophical Considerations

Christine L. McCarthy

59.1 Cultural Studies of Science

Contemporary science education is considered by many to be in need of a fundamental re-structuring, based upon a fundamental re-conceptualization of science. Work in the field of cultural studies of science education attempts to provide the basis for this revision. Prominent themes that are current in the CSSE literature can be traced to a number of classic mid-twentieth-century works in the philosophy and sociology of science. In this section five foundational themes and their sources are examined.

59.1.1 The Sociological Study of Science: Merton

It is uncontroversial that the activities of scientific inquiry are human activities, invariably occurring in a social context. The social context necessarily affects the historical course of scientific inquiry, and the social world is itself affected by the developing science. Sociological studies of science have examined the activities of practicing scientists and explicated the interactive relationship of science in society. Beginning in the 1930s, Robert Merton advanced the sociology of science by conceiving of science as itself a social institution. Merton's work focused on the social structure of science, the relations and interactions internal to, and, perhaps definitive of, the institution of science. Merton, often considered to be the founding father of the sociology of science, argued that science cannot be developed and cannot be maintained, unless certain cultural conditions obtain in the society (1938/1973, p. 254). Absent the favorable cultural conditions, hostility toward science can be expected to occur.

C.L. McCarthy (✉)

M.R. Matthews (ed.), *International Handbook of Research in History, Philosophy and Science Teaching*, DOI 10.1007/978-94-007-7654-8_59,

Merton developed a conception of the ethos of scientific inquiry. This ethos is an "…affectively toned complex of values and norms which is held to be binding on the scientist…expressed in the form of prescriptions, proscriptions, preferences, and permissions" (Merton 1973, p. 269). This ethos is maintained and transmitted by the institutional structure of science. It is possible that some practices which occur in the context of science and which are taken to be scientific actually depart from the values and norms of science. To the extent that they do, nonscientific or pseudoscientific work is being produced under the guise of science. Science in such a case would suffer a collapse from within.

Merton also observed that science can be attacked from without: "science is not immune from attack, restraint, and repression" (p. 267) and "[l]ocal contagions of anti-intellectualism threaten to become epidemic" (p. 267). Advanced scientific work leads to the development of complex theories about the world[1] that cannot be understood without extensive study. Such theories are largely unintelligible to nonscientists. This incomprehension undermines cultural support for science and leaves the majority of persons "ripe for new mysticisms clothed in apparently scientific jargon" (Merton 1938/1973, p. 264). In addition, the organized and continual skepticism characteristic of science will at times threaten the interests of entrenched power holders and/or cast doubt on the truth of deeply cherished nonscientific beliefs. Science is then likely to be threatened by an organized social backlash against it.

Merton identified four institutional imperatives that constitute the ethos necessary for science. The first is an objective *universalism*. "[T]ruth-claims, whatever their source, are to be subjected to *pre-established impersonal criteria*: consonant with observation and with previously confirmed knowledge" (1942/1973, p. 270, emphasis in original). None of the personal or social attributes of the scientist are to enter into the assessment of the truth claims. Merton's universalism rests upon the objectivity of the world itself, the object of scientific inquiry. In science, Merton holds, "…[o]bjectivity precludes particularism. The circumstance that scientifically verified formulations refer…to objective sequences and correlations militates against all efforts to impose particularistic criteria of validity" (1942/1973, p. 270).

Merton explicitly rejects social, cultural, and/or racial particularism, holding that "[e]thnocentrism is not compatible with universalism" (p. 271). While accepting that the historical course of development of science is influenced by its cultural context, Merton rejects the notion that scientific knowledge could have a particular cultural, "national," or class-based content. It is possible, Merton maintains, to compare and assess the merits of inconsistent competing claims to knowledge that might arise in different cultures.

> …[T]he cultural context in any given nation or society may predispose scientists to focus on certain problems….But this is basically different from the second issue: the criteria of validity of claims to scientific knowledge are not matters of national taste and culture. Sooner or later, competing claims to validity are settled by universalistic criteria. (Merton 1942/1973, p. 271, n. 6)

---

[1] The term "the world" herein refers to the set of all entities and dynamic interactions that exist and occur and is synonymous with nature or reality, or simply "what is."

Merton's second institutional imperative in the ethos of science he terms *communism*. This is the assertion that the knowledge acquired by scientific inquiry belongs rightfully to the human community as a whole. "The substantive findings of science are a product of social collaboration and are assigned to the community. They constitute a common heritage…" (1942/1973, p. 273). Merton emphasizes that communal investigation is a necessary aspect of scientific inquiry.

The third imperative is *disinterestedness*. Merton remarks upon "[t]he virtual absence of fraud in the annals of science…" (p. 276) and attributes this honesty not to a superior moral integrity of individual scientists, but rather to the institutional structure of science. Inquiry, to count as scientific, must be subjected to the rigorous scrutiny of the community of qualified scientific peers. Given that scientific theories refer to an objective world, it is likely that peer scrutiny will eventually expose whatever fraudulent or incompetent practices might occur. It is when the institutional structure of science breaks down, Merton writes, that "[f]raud, chicane and irresponsible claims (quackery)" (p. 277) proliferate. "The abuse of expert authority and the creation of pseudo-sciences are called into play when the structure of control exercised by qualified compeers is rendered ineffectual" (p. 277).

The fourth institutional imperative is *organized skepticism*, which Merton considers to be "…both a methodological and an institutional mandate" (p. 277). The commitment to skepticism gives rise to conflict between the institution of science and other social institutions, e.g., religious, economic, and political institutions, when such social institutions demand an uncritical respect for and acceptance of certain doctrines. A revolt against science by the culturally powerful may be launched in response.

Merton's sociological research provides a clarification of the social structure of scientific inquiry and its relations to the wider society. Merton's approach involves empirical study of the practices and norms of the social activity of scientific inquiry. His findings go beyond simple description of characteristics found in scientific practice, to an analysis of which characteristics are necessary and definitive. Merton's approach has been largely replaced in contemporary cultural studies of science by a method of cultural criticism.

59.1.2 The Incommensurability of Scientific Theories: Kuhn

Kuhn's (1962) work, *The Structure of Scientific Revolutions,* cast doubt on the belief that the history of science has been one of cumulative progress in scientific knowledge of the dynamics of the world. Kuhn interprets the history of science as a series of revolutions that bring about fairly sudden and fundamental changes of scientific views of nature. These changes Kuhn calls paradigm shifts, defining a paradigm as a set of "universally recognized scientific achievements that for a time provide model problems and solutions to a community of practitioners" (p. viii).

In Kuhn's view, as long as a particular paradigm is in place, a calm period of normal scientific work occurs. The routine work eventually exposes anomalies, findings that don't fit within the current paradigm, which creates a crisis that can be resolved only by revolutionary change in the current paradigm. Following a paradigm shift, the world is understood in fundamentally different ways. Previously accepted theoretical entities are eliminated from the new conception of reality, and new entities, with new interactive dynamics, take their place. So fundamental is the shift in worldview that the theories belonging to the different paradigms, in Kuhn's view, are incommensurable – the terms in the old theory cannot be translated into the language of the new theory. It would seem to follow that there is no legitimate way to rationally assess the relative merits of the old and new theories or of any competing theories. If this is so, change in accepted theory would have to be driven largely by extrascientific factors that function causally, but irrationally, to determine individual and social subjective states of belief.

Kuhn's work contributed to a fundamental reevaluation of the conception of science, of scientific inquiry, and of scientific knowledge. Kuhn noted that theories about the world that are now judged to be false were once considered to be well justified and were counted as knowledge. He concluded that "…once current views of nature were, as a whole, neither less scientific nor more the product of human idiosyncrasy than those current today" (p. 2).

Kuhn appears to argue that if we now dismiss those widely accepted ancient beliefs about the world as mere myths, we should consider the currently accepted beliefs arising from contemporary scientific inquiry to be equally mythic. Given that the vast majority of belief systems in the past have been judged to be mostly wrong, it appears to follow that the majority of our current beliefs are also likely to be mostly wrong. This line of reasoning is sometimes called the pessimistic induction, pessimistic because it suggests that science proceeds by substituting one wrong system for another, without actually progressing toward true belief.

Kuhn's (1962) analysis is often taken as a repudiation of the possibility of rational bases for theory change. Yet Kuhn's analysis rests on the observation that crises of belief arise because new findings of scientific inquiry cannot be understood given the current explanatory theory. A problem is thus set, and a new theory is sought which will better explain the new observations and the old. Proposed theories are comparatively assessed and judged by their ability to resolve the current theoretical problem. The continued process of theoretical crisis and theoretical resolution of the crisis should be expected to lead to gradual improvement in the theoretical understanding of the world. The history of science should lead to optimism regarding the increasing verisimilitude, or nearness to truth, of scientific knowledge, despite any non-translatability of successive theories. The optimistic view of the growth of scientific knowledge is often dismissed in the cultural studies literature as naïve or as a piece of propaganda deliberately deployed in a political struggle for power and domination.

Kuhn's incommensurability thesis appears to support the belief that concurrent but inconsistent cultural systems of belief about the world are simply different and incommensurable paradigms. On this view, it is thought that no culturally neutral grounds can exist that would allow for reasoned choice among different cultural belief systems. Kuhn's work thus is taken to support the view, prominent in cultural studies of science, that there are no legitimate grounds for considering modern science to be of a special cognitive significance. Scientific knowledge is to be considered merely one system of belief among many others that are equally legitimate.

It is ironic, then, that Kuhn, in 1977, develops a set of five criteria for theory choice in science. The first is accuracy of fit to nature: the "consequences deducible from a theory should be in demonstrated agreement with the results of existing experiments and observations" (1988, p. 278). The second is consistency: a scientific theory should "…be consistent, not only internally or with itself, but also with other currently accepted theories applicable to related aspects of nature" (p. 278). The third is broad scope: a theory's "consequences should extend far beyond the particular observations, laws, or subtheories it was initially designed to explain" (p. 278). Fourth, a theory should be "simple, bringing order to phenomena…" (p. 278). Fifth, it should be fruitful: it should "disclose new phenomena or previously unnoted relationships" (p. 278). These five criteria, Kuhn states, "are all standard criteria for evaluating the adequacy of a theory…they provide the shared basis for theory choice" (p. 278). So, for Kuhn, the strict non-translatability, i.e., the incommensurability, of competing theories identified in his 1962 work does not in fact prevent comparative evaluation of the merits of the competing theories.

Kuhn does argue in 1977 that these and other criteria of theory choice cannot be fashioned into a complete algorithmic decision procedure, binding on all members of a scientific community. Judgment is always necessary in evaluation, and individuals who come to minority conclusions are not ipso facto unscientific. Subjective considerations might not be wholly expunged when individuals make evaluative judgments of the merits of competing theories. But there are, in Kuhn's view, rational criteria for judgment, and an open communal and critical discussion of differing individual judgments promotes judgment on rational criteria. "The criteria of choice…function not as rules, which determine choice, but as values, which influence it" (p. 285).

It is Kuhn's earlier work that has been incorporated into the foundations of the CSSE literature.

59.1.3 Cultural Relativism and Science: Barnes and Bloor

Sociologists Barnes and Bloor develop a relativistic theory of knowledge, which they claim is required by "…the scientific understanding of forms of knowledge" (1982/1994, p. 21). They make three claims. The first two are uncontroversial: "(i)…beliefs on a certain topic vary, and…(ii) which of these beliefs is found in a given context depends on, or is relative to, the circumstances of the users" (p. 22). Their third claim, the "equivalence postulate," however, is problematic. The equivalence postulate states that the truth status of a belief is irrelevant to the explanation of the "causes of credibility" of the belief. This may be true, in many cases; it is common to observe instances of confident belief about the world that would later prove false. But the observation is about the empirical cause of a subjective state of mind of a believing creature. This is not relevant to a theory of knowledge, which poses conceptual and normative questions, e.g., whether or not a particular confident state of belief ought to be counted as knowledge.

Barnes and Bloor, though, stipulate that they will be using the term "knowledge" in a specific way: "We refer to any collectively accepted system of belief as 'knowledge'" (p. 22, n. 5). This stipulation is problematic, however. To believe a proposition is simply to accept that the proposition is true and to be prepared to act as if the proposition is true. But, the subjective belief that a proposition is true, even when collective, itself provides no evidence about the actual truth or falsity of the proposition.

Barnes and Bloor cope with this difficulty by eliminating from their conception of knowledge any considerations of truth. There will be no consideration of the relative merit of different systems of collective beliefs in terms of truth, or of "nearness to truth," or *verisimilitude*.[2] Barnes and Bloor see no problem in their omission of the concept of truth, because they take use of the words "true" and "false" to merely "provide the idiom" through which individuals express their natural subjective preferences for their own cultural beliefs. Barnes and Bloor continue to use the word "knowledge," but their claims about knowledge must be understood to be claims only about collectively accepted systems of belief.

In the absence of concern about truth, any comparative assessment of the merits of different bodies of belief is seriously restricted. Despite Barnes and Bloor's redefinition of the term "knowledge," there remains need for a term that refers to systems of belief that are thought, for good reasons, to be true or at least more nearly true than competing systems. The term "knowledge" has long served this purpose in ordinary English usage.

This suggests another problem with the equivalence postulate. Finding a causal explanation of an individual or collective state of belief is not the same thing as finding *good reasons for* the state of belief. After one has reached a well-grounded explanation about *how* a particular belief was caused, it is still sensible to ask whether it is a good thing that the belief was so caused. Barnes and Bloor, however, collapse the important distinction between causes of believing and reasons for believing and assert that discovery of the causes of belief is identical to discovering reasons for the belief. Having collapsed the distinction, they maintain that the sociology of knowledge is not to be "…confined to causes *rather than* 'evidencing reasons'. Its concern is precisely with causes *as* 'evidencing reasons'" (p. 29).

Seeking causal explanations for states of affairs, seeking the conditions of occurrence of a state of affairs, is a central and legitimate aim of scientific inquiry, and scientific inquiry into the empirical causes of collective belief is interesting and important. But sociological inquiry into the facts of belief acquisition is not an inquiry into acquisition of knowledge, unless knowledge is conceived in the limited *subjective* sense of individual and/or collective belief. Further considerations regarding the concept of knowledge will be taken up in Part 3.

---

[2] Popper's term; see Sect. 59.3.3 for further discussion.

59.1.4 Science as Cultural Tyranny: Feyerabend

Feyerabend, in *How to defend society against science*, develops a broad critique of science as a human endeavor. He writes in support of the wholesale rejection of modern science, on the grounds that achievement of true belief limits freedom of thought:

> [m]y criticism of modern science is that it inhibits freedom of thought. If the reason is that it [modern science] has found the truth and now follows it, then I would say that there are better things than first finding, and then following such a monster. (Feyerabend 1974/1988, p. 37)

Feyerabend writes that scientific knowledge is merely an ideology, no different from the ideology of the Church or of Marxism. He rejects the notion that scientific inquiry is a distinctive mode of activity: "…there is no 'scientific methodology' that can distinguish science from the other ideologies. *Science is just one of the many ideologies that propel society and it should be treated as such…*" (p. 40, emphasis in original).

Feyerabend notes that there are practical educational consequences of his position and approves, writing: "Three cheers to the fundamentalists in California who succeeded in having a dogmatic formulation of the theory of evolution removed from the text books, and an account of Genesis included" (p. 41). It appears that, in Feyerabend's view, maximal freedom of choice in believing is the primary cognitive value to be achieved; having a well-warranted body of knowledge about the world is not a comparable value.

The animus against science that Feyerabend evinces in his writing seems based on a conception of the negative effect an ideology of science would have on humanity. In "Dehumanizing Humans," he speaks of the look on the face of a friend, in which, he says, the whole relationship is written. He asserts that a scientific worldview would devalue this important, albeit subjective, human experience. "This look is not an objective fact…it is not 'scientifically important' and if science takes over, not socially important either" (1996, p. 95).

In "The Disunity of Science," Feyerabend asserts that the objective ontology of materialism that grounds science forces human beings to accept the reality of a world without subjective human experiences. Classical physicists, he writes, "distinguished between the objective world of scientific laws – and this world is without change – and the subjective world of our experiences. They ascribed reality to the former and regarded the latter as an illusion" (1996, p. 39). Philosophers, certainly, have sometimes made this move, and Feyerabend's objection to it are well grounded. As long as creatures having a requisite type of complexity really exist, as they clearly do, subjective states of affairs – feelings, desires, hopes, and beliefs – will also really exist, as states of those creatures. It is possible, however, to reject problematic philosophical theses associated with science without rejecting scientific inquiry in toto.

Yet Feyerabend's belief that science itself is hostile to the most important facets of human experience has become a common one. If scientific inquiry were in fact hostile to human experience and to human values, purposes, and emotions, then a passionate antipathy to science would make sense. But neither scientific inquiry nor scientific knowledge requires a denial of the fact of the qualitative, subjective experiences of human life. Far from denying those experiences, scientific inquiry, in leading to knowledge of the dynamic relations in the world, promotes the human quest for valued qualitative experiences.

Preston (2000) quotes Feyerabend on the disunity of science, its lack of a characteristic epistemology:

> Science is not one thing, it is many; and its plurality is not coherent, it is full of conflict. There are empiricists who stick to phenomena and despise flights of fancy, there are researchers who artfully combine abstract ideas and puzzling facts, and there are storytellers who don't give a damn about the details of the evidence. They all have a place in science. (Feyerabend 1992, p. 6)

The conception of science as all inclusive, so that even storytellers who don't give a damn about evidence are to be counted as practitioners of science, is evident in much of the CSSE literature.

It may be that Feyerabend was not entirely serious in his assertions about science. The essays collected in Preston's *The worst enemy of science?* provide insight into Feyerabend's scholarly intentions, and philosophers of science who knew Feyerabend personally write that he was intentionally provocative and extreme in his assertions about science.[3] But, whatever his intentions, Feyerabend's writings are often taken seriously and at face value. The effect of his writings has been to provide support to contemporary critiques of, and rejection of, modern science as the mode of inquiry that is best able to lead to knowledge of the world.

59.1.5 Science as Cultural Domination: Harding

Harding's feminist work is widely cited in cultural studies in science education literature and exemplifies certain philosophical issues central to current critiques of science (e.g., 1986; 1998).[4] Harding describes her position as a *standpoint* theory, one that values the standpoints of those who are *other* with respect to some cultural milieu. The others with respect to science include women, nonwhite ethnic/racial groups, non-European cultures, and cultures from the past. Taking on others' standpoints, Harding maintains, enables the detection of culturally based distortions in knowledge. Harding's acknowledgement of the possibility of error in belief, and of correction of that error by critical communal discourse, is significant. In accepting this, Harding appears to accept that there is an objective order in nature, i.e., that there are regular patterns of events in nature and that such patterns can be recognized, if an inquiry process properly structured to promote unbiased comparative assessment of theories is developed. In this respect, Harding's position would appear to be close to that of Merton.

---

[3] See also Horgan (1993).

[4] See Grasswick (2011) for an overview of feminist work in the philosophy of science.

Yet, contra Merton, Harding argues that the claims of Western modern science to universality and objectivity should be rejected as illusions. Harding argues that all theories about the regular patterns in nature are social constructs and that all social constructs are strongly influenced by social, cultural factors and by political agendas. Given this, Harding concludes that scientific theories are neither objectively determined nor politically neutral. The bodies of collectively accepted belief developed in different cultures, which Harding takes to constitute the culture's science, should be expected to diverge in both method and content. The problem here is that Harding's conclusion relies on an assumption that any degree of influence on science by social factors negates the claim of science to objectivity. But, absolute objectivity need not be conceptually required. A greater degree of objectivity is the value to be sought in scientific inquiry. The institutional structure and norms of scientific inquiry support the goal of achieving greater objectivity.

Harding maintains that all theories about the world are underdetermined by empirical evidence. She takes this to mean that different and mutually inconsistent theories can be constructed, all of which will be equally consistent with all possible empirical evidence. The best that any scientific theory can achieve, then, is empirical adequacy, i.e., consistency with observational data. "Many socially constituted theories about nature can be *consistent* with nature's order, but none are uniquely *congruent* with it; none uniquely correspond[s] to it" (1998, p. 176).

Harding further maintains that it is impossible to comparatively evaluate different empirically adequate theories, because it is impossible to acquire empirical evidence that would definitively rule out some of the empirically adequate theories. Absent the possibility of disconfirmation through scientific inquiry, in Harding's view, as in Kuhn's (1962) work, it can only be social, cultural, political, and historical factors that determine which theories about the world come to be accepted in a culture.

But, Harding does not take into account the commitment in scientific inquiry to an ongoing search for new evidence, the study of previously unconsidered situations, that will, in creating Kuhnian crises, allow for comparative evaluation of competing theories. The fact that, at an early stage of scientific inquiry, competing theories are equally adequate to current observational evidence does not entail that they will always be. The existence of two or more competing theories constitutes an intellectual problem for the scientific community and encourages intensive scientific inquiry to resolve the problem.

Harding holds that, in practice, persons in positions of social power will make the decisions that establish culturally specific belief systems.[5] The resultant belief system, unsurprisingly, will serve to maintain the existing social power relations. Social power dynamics determine what research projects will be permitted and which will be funded. Power dynamics also operate within the scientific community, determining which observations, and which theories, will be considered authoritative in the scientific community. On Harding's view, it is in principle impossible that continued scientific inquiry might lead to results that would *objectively* decide a scientific issue.

---

[5] See Oreskes and Conway (2010) and Wagner and Steinzor (2006).

Dominance relations occur at the level of individuals, and of social strata, and also at the intercultural level. Harding observes that "Western" culture is currently globally dominant and takes this geopolitical dominance to explain why "Western" scientific theories are currently intellectually dominant. Modern scientific methods of inquiry, and the scientifically generated body of knowledge, on this view, have been imposed on other cultures, in the face of their resistance.

Harding claims not to reject in toto what she calls the "European scientific and epistemological legacy" (p. 125). She does, however, argue that European science should be updated and means by this that it should be reconceptualized as simply one local knowledge system among many others, all of which are to be conceived as of equal intellectual value.

Harding accepts that the theories resulting from scientific inquiry "may well 'work' in the sense of enabling prediction and control" (p. 132), but she does not believe that "working" provides evidence of the truth, or of the nearness to truth, of scientific theories. Harding maintains that quite different and inconsistent systems of knowledge can provide similar levels of prediction and control. She writes that "…the regularities of nature …may be explained in ways permitting extensive(though not identical) prediction and control within radically different and even conflicting, culturally local, explanatory models" (p. 132). Harding's examples, though, serve only to cast doubt on the general claim. She asserts, for example, that "[f]armers in radically different cultures can predict equally well a large range of weather patterns and their effects, just as health care workers in these cultures can predict when illness will occur and how to cure it" (p. 133).

Yet there is abundant evidence that Harding's claim about the equivalent predictive power of scientific and nonscientific belief systems is false. For example, contra Harding, predicting with any significant accuracy the path of a tornado, or a hurricane, requires the instruments of modern science. Losing the weather satellites we currently rely on would destroy the predictive advantages we currently enjoy, wherever such technology is employed. Reliance on alternative, nonscientifically warranted beliefs about health care is likely to be ineffective, except for its placebo effects.[6] While it is possible that some aspects of some alternative health care might be effective, there are no good reasons to accept any such claim in the absence of a rigorous scientific testing of the claim. It is indisputable that nonscientific peoples have developed practices that provide some measure of success in dealing with some problem situations – the fact of survival over time is evidence of this. But organized scientific inquiry such as Merton describes has led to a body of knowledge that permits successful practice in vastly more situations.

Harding writes that it was once possible to naively imagine that scientific inquiry provided a means to achieve or approach true beliefs about the world. "When the ideal results of research could be assumed to be socially neutral, truth or truth-approaching could appear to be a reasonable way to conceptualize the relationship of our best knowledge claims to the natural and social world" (p. 143). But Harding maintains that once the operations of scientific inquiry are understood to be

---

[6] See Bausell (2007) and Singh and Ernst (2008).

dominated by extrascientific influences, as she argues they are, the notion that scientific inquiry can lead to true beliefs, or truth-approaching beliefs, will be discarded. Like Feyerabend, Harding finds all truth claims to be inimical to social discourse. “Truth claims are a way of closing down discussion, of ending critical dialogue, of invoking authoritarian standards” (Harding, p. 145). Rather apocalyptically, Harding asserts “The achievement of truth would mark not only the end of science, but also of history” (p. 145).

But, contra Harding, even the best of scientific theories are not taken, by scientists, to have been absolutely proven to be true. The concept of truth, understood as correspondence of theory to reality, is a regulative ideal in scientific inquiry. But it is well understood within the scientific community that scientific inquiry is an ongoing process of appraisal. A scientific theory, when accepted, is always accepted tentatively, as the best theory to date, pending further inquiry that may falsify it. Nevertheless, a theory may have such strong warrant that it is judged unlikely to be falsified.[7]

Harding’s position has many internal tensions. An orderly and objective reality is accepted, but to develop a body of objective knowledge of reality, involving beliefs that approach truth, is considered impossible. The concept of a universal[8] body of knowledge is replaced by the concept of discrete local knowledges, conceived in the fashion of Barnes and Bloor as collectively accepted bodies of belief. Claims to truth are considered to be means to achieve power or means to destroy free social discourse. The problem with “Western modern science” is taken to be that this mode of inquiry is *as incapable* of delivering a body of objective knowledge as any other mode of inquiry. The claims of science to do so Harding considers to be part of the efforts of the scientific community to achieve cultural domination. Conceiving the problem as one of cultural domination, Harding’s solution seems to be to expose the deceptive nature of modern science and to promote acceptance of the legitimacy of whatever culturally specific belief system is found to be appealing. These positions figure prominently in the CSSE literature. Much less prominent have been the detailed criticisms levelled at Harding’s position by prominent philosophers of science, many of them feminists.[9]

59.2 Cultural Studies of Science Education

Work in the cultural studies of science field lays the foundation for contemporary cultural studies of science education [CSSE]. The advent in 2006 of the journal *Cultural Studies in Science Education* is a significant development. Editors Roth

---

[7] See discussion of Popper, Sect. 59.3.3.

[8] Universal claims are those that apply *to the interaction in question* wherever and whenever that interaction occurs.

[9] Koertge argues that feminist epistemology “…stands in a sharply antithetical relationship to the core values of science” (1996, p. 416). See also Haack (2003) and Pinnick (2005 and 2008).

and Tobin introduce the journal in this way: "The journal encourages empirical and non-empirical research that explores science and science education as forms of culture….A requisite for all published articles is…an explicit and appropriate connection with and immersion in cultural studies" (Roth and Tobin 2006, p. 1). The editors note that the journal will include "…OP-ED pieces that present ideas radically departing from oppressive, hegemonic norms" (2006, p. 2).

It is clear from this introduction that the journal is to be intellectually selective, publishing only work that conforms to the politically and socially based critique of science explicitly established as the norm for the journal. Paradoxically, it appears that this is itself an establishment of an alternative norm that is oppressive and hegemonic, albeit on a local scale.

Work in the field of cultural studies in science education is diverse in some respects. Many studies focus on pedagogical practice, interpreting the particular needs of culturally diverse students and proposing means by which the science educator can meet those needs. Philosophical conceptions of the nature of science, reality, knowledge, and truth are explicitly addressed in some studies. A particular set of positions on these issues, consonant with the positions generally developed in the CSS literature, is an explicit expectation in CSSE literature.[10] In this section I examine selected works in the CSSE literature that exemplify fundamental philosophical commitments in the field.

59.2.1 Pedagogical Practice

Elmesky (2011) provides an example of the pedagogical focus in the field. Elmesky notes that culturally diverse students bring with them "…heterogeneous cultural ways of being …that would be typically considered as unscientific …" (2011, p. 54). Elmesky argues that the teacher ought to incorporate the students' cultural ways of being into the study of science. Taking marginalized African American students to constitute a culturally distinct group, and taking rap music to be one of their cultural ways of being, Elmesky incorporates the creation and performance of rap music into the science classroom. Elmesky provides the following rap, created by the students, as an example of culturally relevant pedagogy:

> People depend on sound to get us around almost everyday we sometimes hate it but then we love it especially when we play even the blind it helps them to find a way to see in mind sound makes vibrations which makes equations so take advantage of this information. (Elmesky 2011, p. 65)

Elmesky states with approval that the rap recognizes that sound travels through vibrations and that the phenomenon can be symbolically represented through equations. Elmesky does not provide any evidence that the exercise has helped students

---

[10] See also Roth and Tobin (2009).

acquire a scientific understanding of the nature of sound. Elmesky instead justifies[11] the incorporation of rapping in the science classroom as a matter of social justice, as a repudiation of the cultural domination based on class and race that she takes to be inherent in science.[12]

Elmesky's account of the enthusiasm of the students suggests that the time given to rapping may serve a positive pedagogic purpose. It appears to permit a relaxed interlude of simple fun that allows the students to return refreshed to the cognitively demanding work of learning science. But Elmesky does not conceive the rapping interlude in this way. The exercise is said to provide the marginalized students to be themselves; it overturns "…the ideologies of the dominant race and class [that] continue to govern what content is taught as well as the frameworks for pedagogical approaches to instruction" (2011, p. 54).

Elmesky does not consider the possibility that a disservice is done to the culturally marginalized students if they end up with a less rigorous, less thorough, instruction in science than culturally mainstream students. Social justice in education requires that the same high quality of instruction be provided to all students, regardless of social or economic status, or unwarranted assumptions of culturally based limitations in capacity to learn. Contra Elmesky, pedagogical methods in science education should be justified by reference to their effects on the acquisition of scientific knowledge, if social justice in education is part of the educational goal.

Meyer and Crawford's "Teaching science as a cultural way of knowing" provides another example of cultural studies work focused on pedagogical practice. The culturally diverse students in this study are Latino, African American, Native American, and English language learning students. Consistent with both Merton (1942) and Roth (2008), Meyer and Crawford conceive of science as a culture having its own rules and operations, "…a dynamic and negotiated way of knowing that is practiced by a particular community…" (2011, p. 530).

Like Harding, Meyer and Crawford regard the scientific way of knowing as just one way of knowing, among many other different but equally legitimate culturally specific ways of knowing. Scientific inquiry, they write "…is implicated in Western ways of knowing…[which is]…an already accepted cultural norm for many mainstream students" (p. 535). Meyer and Crawford state that "[w]ithout culturally relevant instructional practices aimed toward facilitating student border crossing… science instruction incurs a form of symbolic violence, where one way of knowing dominates and seeks to replace others" (p. 532).

There are good reasons to doubt that the everyday cognitive habits of *any* student are well aligned with the norms of scientific inquiry, when he or she begins to study science. The norms of scientific inquiry make it a decidedly unnatural way of thinking, which not only must be learned but takes considerable effort to learn.[13] Yet it is the commitment, in science, to continual skepticism toward currently accepted theories

---

[11] The term "to justify" here means "to give good reasons for" a proposition, belief, or practice and does not imply demonstrative proof.

[12] See also Emdin (2009).

[13] See also Wolpert (1992) and Cromer (1993).

that makes scientific inquiry especially well suited to contribute to the growth of the body of scientific knowledge. Nonscientific ways of thinking, lacking the commitment to organized skepticism, place value on a non-changing body of belief, maintained by indirect cultural norms that prohibit skepticism and by direct coercive force when necessary.

There is no good reason to conclude that students of certain ethnicities or students whose first language is not English would be drawn innately to nonscientific ways of thinking or would experience greater difficulty in learning science than Caucasian speakers of English. The educational challenge, for all students, is to find pedagogical methods that lead to an understanding of contemporary scientific knowledge, at least sufficient to support rational participation in social policy determination, and an appreciation of the distinctive intellectual merits of scientific ways of thinking.

59.2.2 An Ontology of Difference

Roth's (2008) work "Bricolage, metissage…" provides an example of CSSE work that goes beyond pedagogical practice, into the realm of ontology and linguistic meaning.

Roth begins with an analytic claim about language: that being different is generally understood as merely the negation of being the same. Roth argues that, when *difference* is treated as conceptually secondary, instances of identity are valued more highly than instances of difference. Whatever fails to conform to an accepted standard, Roth claims, is considered to be not merely different, but deficient, inferior.

Roth sets out to reverse the posited evaluative bias. He proposes that *difference* be conceived as the primary ontological category, as a concept that is "in and for itself" (p. 898). *Identity* would then be conceived as merely a limiting case of difference, an ideal state that is never fully achieved in actuality. Roth proposes that an ontology of difference should replace what he claims is the currently accepted ontology of purity.

Roth's empirical claim about the negative value currently accorded to difference is problematic. Contra Roth, it seems that whether sameness or difference is more highly valued depends on the type and context of the particular judgment of value. For example, in a dog show, sameness, i.e., close conformation to a breed standard, is the value sought; in a film festival, it is likely to be difference, originality, creativity, and novelty that are most highly valued.

The epistemological implications Roth sees in the proposed ontology of difference are problematic. Knowledge, Roth argues, on this view would no longer be conceived to be a single self-consistent ideal essence.[14] Instead, knowledge would be understood as a "singular plurality" that is constituted by myriad concrete instantiations of knowing. According to Roth, this means that knowledge must be

---

[14] Knowledge is not in fact generally conceived today in this Platonic sense, particularly not in the context of modern science; see Sect. 59.3 for further discussion.

conceived as comprised of many different and mutually inconsistent knowledges. We must, on this view, relinquish "…the idea of *one* true scientific knowledge against which all other forms of knowledge are evaluated, asked to be abandoned, and, still worse, to be 'eradicated'…" (2008, p. 903).

Roth takes his ontology of difference to mean that any cultural accepted interpretation of a term such as "knowledge" counts as a legitimate expansion of the set of all referents of the term. This might, at first, seem to be a laudably open and accepting interpretation of knowledge. The problem is that terms that are given an infinitely extendable reference lose their value as communicative tools. Once there are no limits to the reference of a particular term, there is no longer any communicative point to be served by using the term.

Contra Roth, the crucial linguistic goal is to clarify the different usages of the terms "knowledge," "science," etc., to better understand the various interconnected, or inconsistent, meanings of the terms. Roth's approach, which is to expand the extension of the terms by broadening their definition indefinitely, is linguistically counterproductive.

The difficulties with Roth's ontology of difference, with its conceptual consequences, become apparent when Roth applies his ontology to the practices of science education.

59.2.3 Hybridized Knowledge

Roth develops an account of knowledge that he terms "hybridized knowledge." Roth observes that a global cultural diaspora is under way and that diasporic persons struggle to form new, composite identities that allow them to accommodate to a new culture while retaining cherished aspects of their original culture. Roth then argues that the culture of modern science is distinctive in being fundamentally foreign to *all* human beings and that all persons are diasporic with respect to science. Science, Roth observes, demands that familiar everyday concepts be set aside in favor of concepts of science that are, in a sense, nonnatural, i.e., intuitively implausible. In this, Roth is correct. For example, the familiar notion that the sun circles the earth, rising in the morning and setting in the evening, is dismissed by modern science, because it has been shown to be false. The familiar but discarded view, according to Roth, becomes "…an affront to the legally embodied and administratively enforced culturally (scientifically) correct one-and-only way of explaining this phenomenon" (2008, p. 894).

It is, however, contrary to the scientific norm of continuous organized skepticism for science to coercively enforce belief in the way Roth states. It is possible and common for demonstrably false but familiar ways of speaking, and thinking, about the world to persist alongside scientifically well-warranted theories, when serious consequences are unlikely to arise. But, there are circumstances when the consequences of such nonscientific belief are or would be serious. When certain social policy issues are decided, it is desirable that the most current scientific knowledge be employed. For example, it is common in some cultures to require that children be vaccinated against certain communicable diseases before beginning school. The relevant scientific knowledge is so well warranted that, in the interests of public welfare, even those who disbelieve in vaccination are nonetheless generally required to comply with the vaccination policy. It is possible that this sort of social employment of scientific knowledge counts as the legal and administrative imposition to which Roth objects. There are indeed issues of social ethics that arise with respect to the social use of scientific knowledge. At the most fundamental level of analysis, the reliance upon scientific knowledge in social policy decision-making can be justified only if there is something distinctively valuable about scientific knowledge, when compared to bodies of belief otherwise generated. Such a distinctive value of scientific inquiry and knowledge is what Roth is denying.

Learning modern science on Roth's view is inherently a matter of cultural suppression and the imposition and enforcement of the privileged culture of science. Every person studying modern science, Roth holds, resists that cultural suppression and struggles to construct a hybridized version of knowledge that incorporates the science into the familiar. Roth provides an example of the problems faced by the diasporic science student. He examines a doubly diasporic situation – English-speaking students who are learning science in French, in an immersion context. Roth finds that the students employ a hybrid lingua franca that incorporates elements of both French and English. The same hybridization process is seen in the students' understanding of science concepts.

Roth reports that, after 8 years of learning French and science, neither the language nor the science of the students is satisfactory to their French and science teachers. Roth, though, chides the teachers for evaluating students on the basis of the traditional ontology of sameness. These teachers, in his view, mistakenly believe that modern science and French have ideal essential forms that should be accurately replicated by the students.

Roth evaluates the students' work, instead, in light of his new ontology of difference. He interprets the students' errors (departures from authorized usage) as positive effects of the creativity and tenacity of those who are doubly diasporic. Engaged in two foreign tasks, the students employ all of their cognitive resources, new and old. Roth argues that, in order to learn the new cultures, students must actively engage in them, prior to having achieved an accurate understanding of them. In Roth's view it would be miseducative to insist from the start on accurate replication, as this would inhibit the students' exploration of the two new cultures.

Roth argues that science teachers too often fail to accept and value such hybridized knowledge. Instead, they impose rigid norms of discourse, doing symbolic violence to the students, by disallowing their familiar culturally accepted forms of speaking, thinking, and knowing. The problem seems to be an unwarranted epistemological domination. Roth takes it to be problematic that scientific discourse is "…constituted and considered as superior to any hybrid discourse" (2008, p. 913), while familiar beliefs that originate outside the science classroom are considered to be "…a lesser form of knowing than the one to be inculcated" (p. 913).

59.2.4 Indigenous Knowledge, Indigenous Science

The concept of indigenous knowledge, and of indigenous science as the source of that knowledge, has an important place in the CSSE literature.[15] Proponents of indigenous science make the claim that long-resident peoples have, over many thousands of years, developed sets of culturally specific beliefs about the world and its dynamics. Nonliterate cultures have bodies of belief that have been preserved in strong oral traditions, which are said to have been handed down unchanged through many generations.[16] These bodies of traditional belief are considered to have successfully guided the cultures in acting in the world over vast periods of time, and given this, they are claimed to merit the term "knowledge" and to count as indigenous science.

Ogawa, a proponent of the concepts of indigenous knowledge and indigenous science, redefines "science" in a way that permits traditional beliefs to count as science. Ogawa adopts Elkana's conception of science, who states: "By science, I mean a rational (i.e., purposeful, good, directed) explanation of the physical world surrounding man" (1971, p. 1437). With that broadly inclusive definition in hand, Ogawa is able to conclude that "…every culture has its own science…its 'indigenous science'" (1995, p. 585). Given the redefinition of science, this is merely to say that each culture has its own rational explanation of the world.

The requirement of rationality might be thought to place some limit on what could count as science. But Ogawa makes it clear that, in his usage, even rationality is to be reconceived as relative to the cultural accepted beliefs. Each culture, he argues, has its own worldview, i.e., its own set of traditional beliefs, and each worldview gives rise to its own version of rationality. Having risen from traditional beliefs, each culturally specific concept of rationality invariably affirms that the culturally specific beliefs are "rational" in a culturally specific sense. Thus, the fact that a set of propositions about the world has been widely believed, over a great many years, is taken to count as good reason for continued belief, i.e., continued acceptance of the propositions as true. This interpretation clearly harks back to the work of Barnes and Bloor.

Ogawa is opposed to a doctrine he calls scientism. He first conceives scientism as "…believing uncritically in science…" (1998, p. 106), that is, believing *in* science "…without understanding science" (p. 107). Ogawa's point here is a good one: to believe in science uncritically would be epistemically problematic and would promote a tendency to accept any thesis on faith, as a doctrine never to be questioned. The solution to this problem would seem to be provision of more and better education in modern science, so that an understanding of science could replace "belief in" science. Yet this is not Ogawa's solution.

Ogawa sets out a second, and more standard, conception of scientism. Scientism, Ogawa writes, is "an ideology that identifies valid knowledge only with science"

---

[15] See also Deloria (1997) and Snively and Corsiglia (2001).

[16] Though, in the absence of recorded accounts, it is difficult to test and verify this claim.

(p. 106), and he rejects scientism in this sense.[17] Ogawa develops the educational implications of his anti-scientism and begins with what appears to be a paradoxical claim, the claim that multiculturalism is an inadequate response to cultural diversity. This is so, he argues, because multiculturalism is too often conceived to require mere mention of scientists of diverse ethnicities and cultures and of the contributions they have made to modern science. He considers this approach problematic, because it involves the deprecation of the nonscientific traditional belief systems of indigenous or other nonscience-based cultures.

Multiculturalism might be conceived as requiring a restructuring of science instruction intended to more effectively induct students from diverse cultures into the culture of modern science.[18] Ogawa takes this induction into modern science to be itself a problem, because in the induction process students belonging to non-Western cultures become alienated from their own cultural roots. Ogawa is objecting to modern science in the way Merton considered to be an attack from outside, which is expected when the organized skepticism of science threatens long cherished beliefs. It is troubling that this attack on science "from outside" is now advanced from within the field of science education. Contra Ogawa, to develop the means to critique, and discard, aspects of one's traditional culture is an inherently liberatory process, increasing each student's cognitive and moral agency.

Ogawa proposes to replace the multicultural approach to science education with what he terms a "multi-science" approach. In keeping with Barnes and Bloor's analysis, science is to be reconceived as relative to cultural norms and practices of thinking and knowing. Given this, science educators should "…view Western modern science as just one of many sciences, that is, science in the context of science education need not necessarily be Western modern science" (p. 584). "Scientism," in Ogawa's second sense, would thus cease to pose a cultural threat, since every cultural belief system would count equally as science, by definition. Accepting the legitimacy of indigenous science entails rejecting the notion that modern science is the only source, or the best source, of knowledge about the interactive dynamics of the world.

Ogawa considers it imperative that the indigenous sciences of students, as well as the students' unique personal sciences, be included in science curricula, along with "Western" modern science, "…as one of the main curriculum emphases" (p. 592). Learning "indigenous science" is a matter of studying the ancient traditional beliefs of whatever cultures are included, and incorporating those various beliefs into one's worldview. Content courses in science teacher education programs, Ogawa adds, would need to be revised to include study of a wide array of traditional belief systems of indigenous peoples.

Curiously, modern science, which Ogawa terms "Western" science, is not itself conceived to be an indigenous science. Ogawa observes that many in Western cultures feel no personal affinity to modern science and concludes that modern

---

[17] Aikenhead (2001) provides another example of the anti-scientism position. See also Cobern and Loving (2008).

[18] See also Southerland (2000).

science is uniquely isolated from the everyday lifeworld of even "Western" people. Modern science, Ogawa holds, is inherently alienating because of its ontology: modern science "…pertains to a Cartesian materialistic world in which humans are seen in reductionistic and mechanistic terms" (p.589).[19] It is the alienation of modern science from any particular culture, Ogawa maintains, that allows individuals in diverse non-Western cultures to do modern science. That modern science is not grounded in a specific culture, but is open to all, is taken as evidence that it is merely "…a theoretically materialistic science, …a kind of game open to anybody who will obey its rules" (p.589). The openness of science to all participants might seem to be to its credit, dispelling worries that students from non-Western backgrounds are unsuited for the study of science. But Ogawa sees the openness of modern science as a defect. Science, having destroyed the students' indigenous culture, leaves them adrift, belonging to no culture. The exclusivity of indigenous cultures seems to be, for Ogawa, a positive thing.

Western modern science, in Ogawa's view, is a culturally oppressive institution wherever it occurs. The authority of science, he states, arises only from the consensus of its scientists, and he holds that this socially powerful group imposes its views on nonscientists, i.e., the cultural majority, without their understanding or consent. "[W]estern modern science is justified only by the scientific community itself. All other institutions have been excluded from the 'inquisition' of scientific justification and are expected to accept it without objections or doubts" (1995, p. 589). According to Ogawa, in every cultural setting, including that of the "West," both science teachers and students feel modern science to be a foreign imposition.

The autonomy of science, with its organized skepticism toward long-standing traditions of belief and practice, which Merton lauded, is generally taken in the CSSE literature to be a negative thing. Science education is a matter of indoctrinating students into a destructive worldview, imposed on students against their will. Roth, for example, writes:

> One of the key concerns I have with science education is that it is little different from what religious education has been in the past. It is a form of indoctrination into a form of thinking about the world that has been shown to be detrimental to the well-being of our planet that we both constitute and that is our home, our dwelling. (Barton et al. 2009, p. 194)

It is true that the growth of the body of scientific knowledge has permitted the development of effective technologies that have enabled an enormous increase in the size of the human population. There is little doubt that science has contributed in this way to the creation of serious environmental problems of global scope. But it is the use to which scientific knowledge is put, coupled with a lack of knowledge of or a willful blindness to the consequences of that use, which creates the problems, not the content of scientific knowledge per se. Knowledge of the dynamics of the world is needed if we are to ameliorate the environmental and social problems we face. The methods of scientific inquiry, developed in the context of continuous

---

[19] If Ogawa is classifying Descartes as a materialist, his understanding of perhaps the most famous dualist among Western philosophers is deficient.

critical evaluation in an open community of inquirers, are means of attaining understanding of the actual dynamics of the interactions that constitute the world. The set of scientific methods is understood to be subject to expansion and revision. There is no bar to the incorporation of new methods, provided that the proposed new methods prove able to pass the tests of the organized skepticism essential to science. There is no sense in placing one's confidence in "other" ways of knowing, that is, in precisely those ways of fixing belief that have not been tested or that, having been tested, have failed.

59.3 Philosophical Considerations About Science

Conceptions of science are grounded in philosophical conceptions of the nature of reality, knowledge, and truth. Radically different interpretations of these basic philosophical concepts are clearly possible. Because radically different interpretations will lead to fundamentally different judgments about the value of practices in science education, consideration of these philosophical concepts has a practical importance.

The difficulty is that the philosophical concepts are interrelated and form an intricate network of meaning; they seem to defy separation and independent resolution. Nevertheless, an effort will be made here to examine them here in a more or less linear order.

59.3.1 Scientific Inquiry, Scientific Knowledge

Science developed as an improvement on the everyday efforts of individuals to understand the dynamics of the real situations in which they live and must act. The term "science" refers both (a) to a particular version of the human activity of inquiry and (b) to the intellectual product of that activity, a body of scientific knowledge. Popper's explication of scientific inquiry as a process of conjecture and refutation (Popper 1953, 1959, 1968, 1972) greatly clarifies the nature of science and informs this treatment.

Scientific inquiry, the activity, is the means developed by human beings to enable the discovery of the interactive dynamics of whatever exists, occurs, and interacts, i.e., the nature of reality. The aim of scientific inquiry is to develop explanatory theories about the world that are true of the world, that truly state the dynamic interactions that constitute the world. Scientific inquiry is an ongoing process of self-criticism, directed at the body of scientific knowledge and at the processes of scientific inquiry. The emphasis on continual self-criticism and improvement permits the hope that scientific knowledge, the product of scientific inquiry, will be increasingly determined by the interactive dynamic systems that constitute the world. There is, however, no guarantee that the process will lead to true statements about the world. Even if a statement or set of statements is in fact true of the dynamics in question, it is, by virtue of the nature of the scientific inquiry process, impossible to definitively, absolutely prove that it is true. Judgments about the truth of scientific statements are the all that can be had. Continual openness to the possibility of error is a necessary feature of scientific inquiry. Theoretical structures are always held open to improvement or replacement. Incompatible theories are taken to be in competition.

New judgments, based on new evidence, and/or on new analyses of existing evidence, are continually being made about the relative merit of competing theories. For this reason, the best-warranted scientific theories to date, are generally the more interesting and are the best bet when seeking to guide action. There are no guarantees of successful action, however; actions may fail even when guided by a true theory.

Scientific inquiry is a communal human activity. It requires a group of people acting cooperatively in pursuit of the same goal, the production of an objective body of knowledge of the world, and sharing a distinctive set of norms, methods, and institutions. Science requires a community and a community having a particular and distinctive culture that promotes the general aim, the search for truth. Maintenance of an open, sustained, cooperative, and critical discussion among qualified persons about the theories under evaluation is a necessary condition of scientific inquiry. The institutional structures of science are necessary for that maintenance.

Maintaining a self-critical attitude toward one's existing beliefs is made considerably easier by the public and interactive critical norms of science. The institutions of scientific inquiry, when they are working well, serve as guardians of the constraints of objectivity. Scheffler states that "[t]hese controls [on belief], embodied in and transmitted by the institutions of science, represent the fundamental rules of its game" (1967, p. 2). Ross et al. also consider the institutional arrangements of science to be the key factor in the demarcation of science. "…Science is, according to us, demarcated from non-science solely by institutional norms: requirements for rigorous peer review…requirements governing representational rigour with respect to both theoretical claims and accounts of observations and experiments…" (2007, p. 28). Despite human cognitive shortcomings, we can "achieve significant epistemological feats by collaborating and by creating strong institutional filters on errors" (p. 28).

Critical discussion is a necessary prelude to the experimental testing of competing theories. Focused on the logical merits of the theories, this discussion determines which theories should be experimentally tested and how those tests should be structured. Critical discussion is also required after the experimental testing, to assess the results of the testing. The rigor of communal critical discussion cannot be achieved by a single individual nor by a few individuals of like mind. Each human being is naturally subject to various biases introduced by personal history, personal desires, fears, enthusiasms, etc. The requirement that critical discussion be open and communal provides a corrective influence, as the various biases of the participants are counterbalanced. In any effort to critically evaluate one's own thinking, the cooperation of others, who think otherwise, is invaluable. But, the scope of the discussion is not limitless. Competence with respect to the history and current state of the relevant body of scientific knowledge is a practical necessity. Scientific inquiry does not require the consideration of the groundless assertions of ancient mythologies.

Scientific inquiry requires the use of well-warranted[20] methods and instruments of objective inquiry, and participation in the social institutions of science, that promote adherence to the norms of science. The history of scientific inquiry is a history of innovation and continued improvement, not only in scientific knowledge but also in the methods, instruments, and institutions of inquiry process itself.

Scientific inquiry, in Popper's conception, proceeds by a process of "conjecture and refutation." The generation of new ideas, conjectures, or, simply, guesses about the world is a creative human act, and this is the necessary first step in scientific inquiry. The source of a new conjecture is not in itself important; conjectures about the world might arise from prescientific myths, from inborn dispositional beliefs, or from dreams, etc. But not all conjectures are equally worth testing. The better conjectures will be bold, i.e., will have high informational content, and will make claims about the world that contradict current theories.

Scientific method cannot be accurately characterized as a simple, and yet universal, set of procedural steps. But, it is not the case that any activity, nor even any inquiry activity, counts as scientific. Over time, diverse inquiry practices that serve particularly well in severely testing theories about the world are identified, formalized, and adopted, tentatively, as methods of scientific inquiry. The methods of scientific inquiry form a vast and highly varied set, which is always subject to testing, revision, expansion, and improvement. Judgments about the quality of methods used in an inquiry are made continually and can only be made by scientific peers who have the requisite technical methodological knowledge.

A body of scientific knowledge is the intellectual product of scientific inquiry. Explanatory theories about the world, and the critical discussions of them, constitute the intelligible content of scientific knowledge. It is necessary for further scientific inquiry that the contents of the body of scientific knowledge be formulated linguistically and/or mathematically and that these formulations be set out in a physical form that permits open public scrutiny and evaluation. All of the contents of scientific knowledge remain open to continued public appraisal, and the best-warranted theory at one time may, on reappraisal, be demoted or may be judged to be false.

The contents of knowledge, belonging to Popper's *third world*, i.e., the world of the intelligible, are objective, i.e., real objects, real existents in their own right. Though the intelligible contents of the physical body of knowledge are the products of human activity, these intelligible objects are largely autonomous, in that they have, in their own right, properties and relations that are unaffected by human thoughts about them.

---

[20] The term "well-warranted" refers here to those theories, practices, means, etc., that have been subjected to rigorous testing and critical evaluation and have been judged to have done well in standing up to the scientific scrutiny, following Dewey's (1929) usage.

The current body of well-warranted scientific knowledge must at the least be internally consistent, if it is to have any prospect of being true of the world. Discovery of inconsistencies in the current theories about the world presents a scientific problem, to be solved by further scientific inquiry. A distinction is needed between current scientific theories, the possible truth of which is still being investigated, and theories that have been refuted or that have failed to succeed in competing with other theories. The latter remain in the body of scientific knowledge but are consigned to the archives, available for further scrutiny, but not considered in the scientific community to be worth further scrutiny.

A question is often raised: Is the content of the current body of scientific knowledge dependent on culture or on the world? The alternatives seem to be mutually exclusive, so it is not surprising that conflict has arisen over this question. Gieryn describes the conflict as a science war and places the combatants into two camps. Those in the "science studies" camp consider scientific knowledge to be culturally relative, simply a body of collectively accepted beliefs. Those in the "science defenders" camp consider scientific knowledge to be universal, equally applicable across cultures, a body of statements about the world that, if not true, are at least near to the truth (1999, p. 344).

There is no doubt that scientific inquiry is a historical process and that the events in that history are contingent, not necessary. Given this, the contingent events of human social life, and cultural circumstances, can and do affect the historical course of development of scientific knowledge. Given this, it is possible that activities of bona fide scientific inquiry could, in different and *communicatively isolated* human cultures, be developing differently over time. But it is a mistake to conclude, as cultural studies of science theorists generally do, that scientific inquiry and the intellectual product thereof, scientific knowledge, is therefore dependent upon the specifics of cultural history.

It is possible that members of two mutually isolated cultures could each independently develop a genuine culture of scientific inquiry, having the norms, practices, and institutions necessary for the practice of science and that these cultures would engage independently in scientific inquiry into the same natural phenomenon. It might happen that various explanatory theories are proposed in each isolated culture and that the competing theories are subjected to severe experimental testing and open and critical communal discussion in each culture. It is possible that judgments about the best theory of the entities and dynamics of the world in one culture would be substantially different from and inconsistent with the judgments of the other culture. The science developed in each culture is thus dependent, historically, on the unique course of events in each culture.

But the moment the isolated cultures come into communicative contact, the incompatible scientific theories come into competition. Assuming that it is the same phenomenon that is being investigated, there can be only one set of statements that truly states the dynamic interactions that constitute the interactive system in question. The presence of two or more different theories, each intended to be that set of true statements, simply sets out a new scientific problem. The situation would indicate to scientists in each previously isolated scientific community the need for further scientific inquiry to assess the relative merits of the competing theories. The theories are historically dependent on culture, but the truth, or nearness to truth, of the competing theories is not relative to culture.

The competing theories may persist side by side for a long time, pending evidence that refutes one or another of the theories. Perhaps each theory will give way to a new theory, one that is a better warranted and offers a better explanation of the phenomenon. But, in science, the appearance of two competing theories about the same phenomenon always presents a scientific problem to be solved. Refusal to engage in that reassessment of theories required by the norms of science is a clear indication that the supposed science of one of the cultures is not, after all, genuinely scientific.

It is rational to prefer, as a basis of action, the theory that has best survived severe empirical tests and communal critical discussion (Popper 1972/1995, p. 22). But acceptance of a scientific theory always remains tentative, no matter how successfully it survives severe empirical testing and critical evaluation.

59.3.1.1 Falsifiability

It is impossible to speak sensibly about science unless science can be conceptually distinguished from nonscience, from pseudoscience, and from speculative metaphysics masquerading as science. Popper distinguishes scientific theories from other theories that "…though posing as science, had in fact more in common with primitive myths than with science" (1953/1988, p. 20). It is clear from the CSSE literature that the demarcation problem is still a live question and one that has practical consequences both in education and in society at large.

Popper argues that the key to the demarcation problem is the falsifiability of scientific theories. To be scientific, a theory must be "…*incompatible with certain possible results of observation*" (p. 22, emphasis in original). According to Popper, "[a] theory which is not refutable by any conceivable event is non-scientific. Irrefutability is not a virtue of theory (as people often think) but a vice" (p. 22).

The initial conjectures about the world, which will be influenced by the contingencies of observation and inductive inference, must be formulated as testable hypotheses that specify what events must occur, when specified actions are taken under specified conditions – those actions under those conditions constitute the experimental test. Observing the events expected to occur provides a measure of confirmation of the theory; repeated confirmations are the basis of inductive inference that the theory is likely to be true or near true.

Inductive reasoning fails, however, as a method of scientific reasoning, because the scope of every scientific theory must go beyond the evidence obtained from any finite set of confirming instances (Popper 1953, 1959, 1972). In contrast, observation of events predicted by theory to be *impossible* serves logically to show the theory to be refuted. If the observation is judged in the scientific community to be a good one, if it is replicable, and judged not to be the result of error, the rejection or revision of the refuted theory is logically required.

Popper's falsifiability criterion for science does not constitute a decision algorithm to be mechanically applied to particular theories. It is not the case, in theory or in practice, that a single failed prediction is sufficient to falsify a theory. It is unlikely that events observed will perfectly match the events predicted based on a hypothesis intended. The events in the world that constitute the context of the experiment will affect the observation process in unanticipated ways. Calculations from the theory of the observations that would falsify the theory will include assumptions that are not well grounded and be incorrect. Judgments about the meaning of particular experimental results are an ineluctable part of the process of scientific inquiry.

59.3.1.2 Science and Pseudoscience

The ability to distinguish science from nonscience and from pseudoscience, and good scientific inquiries and theories from poor, is of the utmost cultural importance. Goldacre gives a detailed account of the prominence of pseudoscience in contemporary medical practice, in the form of complementary and alternative medicine [CAM]. Goldacre identifies a number of factors that work to undermine public understanding of science, even in cultures that one might expect to be most thoroughly scientific, and draws a discouraging conclusion. Addressing purveyors of pseudoscience, and opponents of genuine science, Goldacre says, "You win":

> …you collectively have almost full-spectrum dominance. Your ideas—bogus though they may be—have immense superficial plausibility, they can be expressed rapidly, they are endlessly repeated, and they are believed by enough people for you to make very comfortable livings and to have enormous cultural influence. You win. (Goldacre 2010, pp. 253 and 254)

Goldacre, however, sets out to counter the trend and explains crucial aspects of scientific reasoning that differentiate science from pseudoscience. Bausell, also focusing on the plausibility to many of complementary and alternate medicine, identifies numerous impediments to reasoning which plague human beings: "the family of logical, psychological, and physiological impediments to connecting cause and effect that necessitates the conduct of scientific research in the first place" (2007, p. 35).

Oreskes and Conway, in *Merchants of Doubt* (2010), document current efforts in the United States to keep well-established scientific knowledge from affecting governmental policy decisions. One effective tactic is to call for *more* science, for sound science, for critical reassessment of scientific findings. Such calls might seem to be the epitome of dedication to the methods of science. The problem is that well-warranted scientific knowledge is often countered and effectively undermined by well-funded disinformation campaigns that promote pseudoscience as science and that denounce genuine science as "junk science."

The proliferation of pseudoscience is a major problem in contemporary society.[21] CSSE theorists contribute to the problem in consistently fail to distinguish science,

---

[21] Also see Binns (2011), Gauchet (2012), Kitcher (1998), Morrison (2011), Wagner and Steinzor (2006), and Zimmerman (1995).

not only from pseudoscience but even from nonscience; even the possibility of drawing, the conceptual distinction is denied. This is the direct logical consequence of the CSSE conception that all collective systems of belief count equally as knowledge and that all methods of achieving collective belief count as but different sorts of science. In collapsing the distinction between scientific inquiry and other sorts of inquiry, CSSE theorists undercut educational efforts to bring students to understand the nature of science.

59.3.1.3 Objectivity

Objectivity is an epistemic virtue characteristic of science. Individual or collective objectivity is achieved to the degree that believing is influenced by objective factors, i.e., the controlling force of the dynamics of the world, and the constraints of logical consistency. Scheffler states the relation of science and objectivity:

> …*de facto* science articulates, in a self-conscious and methodologically explicit manner, the demands of objectivity over a staggering range of issues of natural fact, subjecting these issues continuously to the joint tests of theoretical coherence and observational fidelity. (Scheffler 1967, p. 13)

Daston and Galison (2010) trace the rise of objectivity as an epistemic virtue associated with scientific inquiry to the 1800s. Images of natural objects captured by mechanical devices, e.g., photographic plates, were considered to be objective because they would “preserve the phenomena” from the imaginative subjective impressions, intuitions, and biases of the inquirer. They conceive objectivity in this way: “To be objective is to aspire to knowledge that bears no trace of the knower – knowledge unmarked by prejudice or skill, fantasy or judgment, wishing or striving” (p. 17). Prior to the adoption of the ideal of objectivity, they claim, it was common practice for observers to discard discordant observations as defective and, guided by personal intuitions of truth and essential form, to seek out the examples that would seem to verify the favored theory.

To achieve an ideal state of perfect objectivity is in practice impossible and is sometimes conceived as an unnatural cognitive state for human beings.[22] But the employment of instruments that preserve the phenomena, coupled with public participation in studying the preserved artifacts, promoted the emergence of objectivity as an ideal or regulative idea for scientific inquiry. Objectivity, as an epistemic virtue, requires commitment to acquiring beliefs about the world that conform, as much as possible, to the actual states and dynamics of the world. In scientific inquiry, the goal is to design interactions, observations, that serve as tests of hypotheses about the world. Scientific institutions and norms are consciously designed to promote the achievement of objectivity.[23]

---

[22] See Wolpert (1992) and Cromer (1993).

[23] See Longino (1990), for another view.

Wolpert argues that scientific modes of thinking about the world are radically different from commonsense thinking about and conceptions of the world. Commonsense ideas of motion, for example, are generally not correct, and the explanations of motion found in modern physics are strongly counterintuitive. "Generally…the way in which nature has been put together and the laws that govern its behavior bear no relation to everyday life" (1992, p. 6). The need to commit to objectivity as an ideal guiding belief formation is one factor that makes the scientific mode of thought so different from everyday casual patterns of thought. Objectivity requires a willingness to be critical of one's current beliefs, even those that are comfortable, traditional and/or cherished. "Being objective is crucial in science when it comes to judging whether [one's] subjective views are correct or not. One has to be prepared to change one's views in the face of evidence, objective information" (Wolpert 1992, p.18).

Cultural studies theorists of science education are on solid ground when they observe that many students experience considerable difficulty in the study of science. To achieve an understanding of scientific inquiry and scientific knowledge does require the elimination of erroneous beliefs. Some students may indeed refuse the option to learn scientific knowledge and methods of inquiry, opting instead to maintain nonscientific traditional beliefs about the world. But the value of the scientific inquiry as the means of gaining knowledge of the world remains.

Ross, Ladyman, and Spurrett speak out "in defense of scientism." They argue that scientific inquiry is in fact the only means by which well-warranted and hence likely-to-be-true beliefs about the world can be acquired:

> …science just *is* our set of institutional error filters for the job of discovering the objective character of the world—that and no more but also that *and no less*—science respects no domain restrictions and will admit no epistemological rivals. (Ladyman and Ross 2007, p. 28, emphasis in original)

The only way to make a plausible case for there being some *other* way of knowing the world is to reconceive "knowing" so that the term refers to something other than having an accurate understanding of the world. It would be better, communicatively, to choose a different term.

Knowing the world scientifically, while highly valuable, is by no means the *only* valuable state worth experiencing. Esthetically appreciating the world is an eminently valuable state and a significant part of the full human experience. Rejoicing in the world, valuing the world, feeling a passionate connection to and responsibility for the world, and having fun in the world – these are all valuable and worthy states to experience. Imaginative stories about natural events and their meanings can be profoundly moving, emotionally, and can convey important social and personal values and thus have value. But none of these states or activities count conceptually as knowing. To conceptually distinguish knowing states, and efforts to know, from other states and other efforts does not in itself diminish the value of the other-than-knowing aspects of life. The animus against scientism, and against science, seems to rest on an unrecognized assumption that only that which counts as knowing, or as the means to knowing, counts as valuable. Having accepted that assumption, it seems important to insist that all valuable aspects of life must count as "ways of knowing," albeit very different ways. The better resolution, though, is to reject the false assumption that the sole experience that is of value in life is knowing.

59.3.2 The Object of Scientific Inquiry

59.3.2.1 Reality

Questions about the nature of reality are questions of ontology. Some of these questions are of ancient origin, e.g., is reality made up of material substance, or mental substance, or both? Reality might be conceived dualistically, allowing for both physical reals and nonphysical mental of spiritual reals. Alternatively, reality might be conceived monistically, allowing for only physical reals, e.g., chairs, dogs, planets, stars, electrons, and photons, or, alternatively, for only nonphysical reals, e.g., spirit, mind, and consciousness.

Today the question might be whether the matter and energy of contemporary physics exhaust the realm of reality or whether there is something else, in addition to the physical, that is also real, such as the mental, the spiritual, the intelligible, and the divine, or perhaps, consciousness. To be other-than-physical, the posited reals would need to be unconstrained by physical dynamics.

Popper divides the real into three distinctive worlds. Popper's first world is that of the *physical*, including the dynamic interactions thereof; the second world is that of the *mental*, of subjective states of belief, of knowing; and the third world is that of the *intelligible*, of statements, arguments, theories, and scientific knowledge.

In Popper's view, science involves the real things of all three worlds. The first world, the physical world, is clearly involved: physical human actions that have observable physical effects constitute empirical tests of theories. The second world, the mental world, is involved: human believing, human thinking, is required in the generation of hypotheses and in the critical discussion leading to evaluative judgment.[24]

The third world, the intelligible world is involved: linguistic formulations of hypotheses, theories, and arguments are required throughout the inquiry process, and theories and the critical discussions of them constitute the body of scientific knowledge that is the product of scientific inquiry. It is the casting of thoughts into linguistic form, itself a physical form, that produces intelligible objects and makes possible the ongoing public, critical examination that is a necessary characteristic of science.

Scientific inquiry begins with theorizing about the interactive dynamics of the physical world. This is not to say that only physics can be scientific – systems of dynamic interaction can be studied at any level, and an ecosystem is as legitimate an object of scientific study as a system of subatomic particles. Dynamic states of

---

[24] To call this the "mental" world accords well with common usage but can introduce unnecessary confusion, should the term "mental" suggest the traditional ontological dualism, with "mind" existing as a nonmaterial mental substance.

affairs of organic beings are as open to scientific inquiry as those of inorganic beings. Scientific inquiry into the dynamic states of conscious organic beings is equally feasible. Having a thought is not fundamentally different from having an urge or having a cold – all are complex dynamic states of affairs of organic beings. The mental world that Popper posits appears to be a part of the physical world.

To make sense of the practices of scientific inquiry, an assumption of metaphysical realism is necessary.[25] Metaphysical realism is the thesis that the world is objective, meaning that the dynamic interactions and resultant states of the world are as they are, regardless of any thought, wish, or belief about them.[26] There is a complication, though. Thoughts, wishes, beliefs, etc., are themselves objectively real; like all real thing/events, in a particular sense, these are mind independent. That is, the existence of a particular mental state is unaffected by thoughts, wishes, and beliefs about its being or having been in existence, except when there is an ordinary physical causal connection. This is not to deny that organismic states of affairs, including thoughts, beliefs, and desires, are, potentially, causally interactive with other objective real things and events. Causal interactivity is the very hallmark of the real, and if internal cognitive states were *not* causally interactive, that would be reason to doubt their physical reality (see Khlentzos 2004). It is to deny that the entities and interactions that constitute the world are dependent upon the operations of a postulated non-physical mind.

Scientific realism builds on the thesis of metaphysical realism. Scientific realism is the thesis that the theoretical entities in use in well-warranted scientific theories are to be understood as objectively real, and that statements about those entities are to be understood to be true, or false. Ellis sets out a well-developed version of scientific realist ontology. According to Ellis, the scientific realist accepts “that an ontology adequate for science must include theoretical entities of various kinds, and that it is reasonable to accept such an ontology as the foundation for a general theory of what there is” (2009, p. 23).

Ellis employs an argument to the best explanation in support of his scientific realism: “…if the world behaves *as if* entities of the kinds postulated by science exist, then the best explanation of this fact is that they really do exist” (2009, p. 24). He distinguishes descriptive theories, those that posit real entities, from theories that explain by developing idealized models of interactions. The idealizations employed in the latter, e.g., a frictionless surface, are not intended to be understood as really existing. The scientific realist has no need to take idealizations to actually exist.

In contrast, Ellis argues, the entities postulated by an accepted “causal process theory” should always be understood realistically. If theory A “is agreed to be the best causal account that can be given of the occurrence of some event E, and A is a satisfactory theory, then the entities postulated in A as the *causes* of E must also be thought to exist” (p. 31). The argument for real existence of theoretical entities is strengthened when the posited entities are found to have additional causal effects,

---

[25] Although it could be that metaphysical realism is false and that the practices of scientific inquiry actually do not make sense.

[26] See Devitt (1984/1991), Leplin (1984), and Melnyk (2003).

beyond those initially predicted. Ellis, like Khlenzos, holds that "causal connectivity is what characterized real things…real things should have a range of different properties, and so be capable of participating in various causal processes" (p. 32).

Ellis observes that the metaphysics of scientific realism quite naturally accords with scientific practices of inquiry, for the simple reason that this metaphysics "has been developed out of science, specifically to accommodate the developments that have occurred in this area" (p. 115). Given this, it is unsurprising that scientific realism "makes good sense of the nature and structure of scientific knowledge" (p. 115). But this ontology, like any ontology, is not intended only to be used in the context that gave rise to it. Ellis argues that scientific realism is likely to provide a sound basis for understanding in other areas, such as mathematics, and moral and political philosophy.

The scientific realist position sketched out here is a controversial one. Many philosophers of science, and scientists, adopt instead an instrumental conception of science. Instrumentalism in this context is the thesis that the statements that constitute scientific theories are not to be understood as truth-functional claims about reality. Instead, theories are to be understood as convenient, useful mathematical devices that happen to work well when making predictions about observable events. Instrumentalists argue that it is *not* the task of physics to arrive at true statements about things that really exist, particularly when the posited entities are unobservable. Ellis's separation of descriptive theories from theories specifically intended not to be descriptive seems to accomplish the conceptual work necessary to end the dispute.

Real events in the world affect human well-being, for better or worse, and these events are notoriously unresponsive to organismic states of wishing, desiring, believing, etc. Human action in the interactive world is required; that action, to be sufficiently successful in meeting human needs, must be guided by beliefs that are true or near to true. Instinctive dispositions to act in certain ways under certain conditions must have been sufficient at some time in our evolutionary history. But such dispositions no longer suffice. Beliefs must be carefully chosen, formulated, and tested for efficacy in guiding action successfully. The best of the tested beliefs are considered to be known.

Scientific inquiry is often still motivated by the pragmatic need to know, though it is often motivated today by the simple desire to know. In either case, the general aim of scientific inquiry is to seek truth, and its more achievable goal is to produce explanatory theories that enable humans to understand the world and to act more or less successfully in the world. A genuine explanatory theory must make true or nearly true statements about real entities and their real causal interactions.

59.3.3 Knowledge and Knowing

The term "knowledge" is used in a great many ways.[27] It is often used to refer to a particular subset of beliefs, those beliefs that are coupled with a strong feeling of

---

[27] See, for example, Sosa (2011).

certitude. Popper calls this the subjective sense of knowledge (1972/1995). Knowledge, in this subjective sense, is an organismic state of affairs of the individual; when the state of knowing is widely shared among a group of individuals, it is a cultural state of affairs. In either case, subjective knowing is an ordinary physical state of a very complex entity. Popper places these states of affairs in his second world, the world of mental entities, populated by knowings, as well as believings, desirings, wishings, fearings, etc.

A claim to *know* serves a linguistic function, that of providing a particular assurance. It conveys the speaker's claim that the proposition said to be known is not merely believed to be true, but is believed to be true for good and compelling reasons. When a person asserts that he *knows* that a storm is approaching, the intention is to assure the listener that this proposition is very well warranted, that it is true or near to truth, and that it ought to be relied upon as a guide to action.

States of individual or collective knowing can be divided into two sorts, based upon the quality of the inquiry process that led to the state of knowing. On one end of the continuum, there are casual inquiry processes, including minimal inquiries barely worthy of the name. On the other end, there are the carefully designed ongoing programs of concerted inquiry that count as scientific inquiry.

A casual inquiry process is often considered to be good enough to warrant the assertion "I *know*," particularly in everyday situations in which the stakes are thought to be low. Yet even at this low level of inquiry, there are standards. A body of casually acquired subjective knowledge is expected to be self-consistent. Revision and improvement of the body of knowledge is expected, by an ongoing assessment of the warrant of the beliefs, and the elimination of error. Confidently believed propositions which have been tested and have failed the test should lose the status of subjective knowledge.

Popper develops the concept of objective knowledge and distinguishes this from subjective knowing (1968/1995). Objective knowledge, in Popper's view, belongs to his third world, "…the world of intelligibles, or of *ideas in the objective sense*; it is the world of possible objects of thought: the world of theories in themselves, and their logical relations; of arguments in themselves; and of problem situations in themselves" (1978/1995, p. 154). These intelligible objects are man-made. But, having been made, these objects have an existence that is largely autonomous of the world of subjective thinking, believing, and knowing. The existence of objective knowledge does not require the existence of individual or collective subjective states of believing.

The objective body of scientific knowledge is distinctive in that it is the product of intentionally devised and tested methods of scientific inquiry. The goal of scientific inquiry is to generate theories about the complex dynamics that constitute the world that are true or near truth. The body of scientific propositions is gradually improved by the elimination of error, made possible by the process of severe testing and critical communal evaluation. The availability of this objective knowledge permits the gradual improvement of individual and collective subjective states of knowing.

There is a pragmatic advantage to employing the set of propositions that have best survived the scientific inquiry process to guide one's action. One will be better able to predict the effects of interactions in the world and to effectively act in the world. The severe testing and critical comparative communal assessment of competing theoretical explanations are the means to achieve this advantage. The norms of scientific inquiry and the institutional structures that permit and promote adherence to those norms are uniquely suited to developing knowledge in this subjective sense.

59.3.4 Truth

An important concept, truth, has been left for last. What is meant by the term "true"? The ordinary language usage of the term "truth" is explained well by the correspondence theory of truth. On this theory, a proposition about the world is "true" if and only if the relevant state of the world actually *is* the way it is stated to be. A state of the world is the truth-maker for every true proposition. Every true statement corresponds, in this sense, to some state of the world; every false statement fails to so correspond.

The correspondence theory of truth requires, clearly, that there be a world, but makes no assumptions about, nor has implications for, specific theories about the world. Any ontological theory can be matched with the correspondence theory of truth. When truth is understood as correspondence, the truth of a proposition provides a good explanation for the success of action taken on the basis of belief in that proposition.[28] Truth, understood as correspondence of the statement to the actual state of affairs, is the ideal goal of scientific inquiry.

Popper conceives truth as correspondence to reality, i.e., to the facts, to what is. Popper's conception of science requires this concept of truth. In developing the demarcation criteria for empirical science, Popper writes:

> …I was very far from suggesting that we give up the search for truth: our critical discussions of theories are dominated by the idea of finding a true (and powerful) explanatory theory; and *we do justify our preferences by an appeal to the idea of truth*: truth plays the role of a regulative idea. *We test for truth*, by eliminating falsehood. (Popper 1972/1995, pp. 29, 30)

The correspondence interpretation of truth is commonly accepted among philosophers; Vision (2004) develops a strong defense of a correspondence. But this interpretation is often considered by cultural theorists and postmodern relativists to be fatally flawed. The theory fails, it is often said, because there is no way for the human organism to have *direct access* to the actual states of the world, and there is thus no way to make the required comparison between (a) statements *about* the world and (b) the world itself. Absent direct access, it seems that on the

---

[28] But note that true belief is neither necessary nor sufficient for successful action.

correspondence theory of truth we could never determine, with certainty, the truth or falsity of any of our statements.

There are several problems with the criticism. The argument at best only shows that without direct access to the world, humans could not *find out* which statements are true and which false. But, it would be possible to could keep the correspondence theory of truth and accept that humans are doomed to ignorance of truth. But this is not necessary – it would be possible to accept the claim that humans do not direct access to the world, but do have sufficient access to the world to make critical judgments, based on good reasons, about the truth of our theories.[29] Or, one could accept the claim that causal interactivity of humans in the world provides the only form of direct access that is needed.

If one rejects the correspondence conception of truth, one might opt instead for an anaphoric theory of truth, conceiving truth as a pro-sentence forming operator.[30] Or, one might adopt a coherence theory of truth. On the coherence conception, each statement in a set of statements is considered to be true, provided only that the set as a whole is internally self-consistent. In a coherence theory of truth, the truth-maker for a statement is not the state of the world, but rather the internal coherence of the set of statements. The problem with this conception of truth is that, on this view, different and mutually inconsistent sets of statements would all be true, provided that each set is itself internally consistent.

Alternatively, one could choose to eliminate the concept of truth from knowledge entirely. Scientific theories could be understood to be, not true, or nearly true of the world, but instead "empirically adequate." In this case, the only claim made with respect to the theory is that it adequately accounts for the data at hand. An empirically adequate theory is often considered to be replaceable by any of an infinite set of different theories, each of which also accounts for the data. More radically, theories in science might be conceived to be nothing more than convenient fictions, contemporary mythologies developed communally by adherents to the culture of science, having no advantage over the different mythologies developed in other cultures. On this view the sole criterion for knowledge is *viability*, i.e., the mere survival of belief in the proposition. This interpretation of the relation of truth to knowledge is the one that is often in evidence in the CSSE literature.

59.4 Conclusion

Reality, knowledge, truth, and science – these interconnected concepts must form a coherent set, if any of them are to make sense. The concept of knowledge requires that there be some object of knowledge, a reality, to be known, and which can be known, at least in part, if knowledge is to be possible. Truth, understood as

---

[29] See also Lynch (2005).

[30] See Grover et al. (1975), pp. 73–125.

correspondence of propositions to reality, is a regulative ideal for knowledge, an ideal goal to be increasingly approached. There being no "book of correct answers," judgments must be made, continually, as to the quality of the body of knowledge developed to date, with the intention to improve upon the body of knowledge. Given this process, it should be expected that the best knowledge of the day will not be as good, i.e., neither as extensive nor as close to truth, as the body of knowledge that will be developed. But changes in the body of knowledge constitute improvements in understanding; they are not mere fluctuations arising from whim or fashion.

Scientific inquiry differs markedly from other means of belief acquisition in its explicit commitment to maintaining a continued attitude of critical skepticism toward the propositions of the current body of knowledge. Ongoing public testing of that which is currently accepted as knowledge is *de rigueur*, a necessary condition of science. Open, critical discussion of all aspects of the process of inquiry and the results of the inquiry is also necessary. Judgments that arise from that discussion are held open to question, and progress is conceived as the ongoing elimination of error. Intentionally seeking for error in the current body of knowledge is the goal of the inquiry.

Being fully real interactants, human beings have no shortage of access to reality, though understanding the interactions we experience is no easy matter. Having a need for such understanding, for knowledge, and also a passion for knowledge, human beings have developed a complex social institutional structure, science, that promotes the effort to understand the interactive dynamics of the world, to know. The social institution of science does not work perfectly in promoting knowledge of the world – this should go without saying. But this constitutes a social policy problem to be addressed, not an indictment against the social institution of science *tout court*. To have an organized social system dedicated to the testing of propositions about the world and open to criticism and improvement is better than not to have such a system. To make use of the scientific knowledge that emerges to guide individual belief and collective social policy is a good thing, better than to make use of beliefs otherwise produced. These are value judgments, not certainties, but they appear to be well grounded. If so, one of the principal educational projects must be to convey to new generations the nature and value of the social institution of science.

Matters that should be of major concern for science educators arise in the CSSE literature, traceable to the philosophical positions underlying much of that literature.

The chief concern is that, in the CSSE literature, scientific inquiry is not clearly distinguished from other sorts of activities nor is it held to be distinguishable. In the absence of this conceptual distinction, no method of generating propositions and of fixing belief in them can be legitimately excluded from the science classroom. The phrase "other ways of knowing" is ordinarily conceived to refer to ways of generating individual or collective systems of belief (subjective knowing) that are *other* than scientific. As such, they can be easily seen to be out of order in the science classroom. So, for example, a close reading of some form of sacred scripture, even though it would lead to subjective states of knowing, would be justifiably excluded. Close study of time-honored oral traditions about the world would, by the same token, be properly excluded.

But in the CSSE literature, purported other ways of knowing are reconceived and are taken not to be other than science, after all. Instead, they are taken to be forms of science, albeit radically different forms (recall Roth's ontology of difference and the "singular plurality" he employs in dissolving conceptual distinctions). Given this, ancient traditional stories about the world, as well as religious, ideological, and political doctrines, must be counted as forms of science, in the new, all-inclusive sense.

Explicit advocacy of this revision in meaning is common in the CSSE literature and is entailed when the philosophical groundwork of the CSSE literature is accepted. The loss of the concept of science as a distinctive form of inquiry generating a distinctive body of knowledge would constitute an enormous cultural change. The resultant cultural endorsement of nonscientific, and hence poorly warranted, belief systems about the world would have negative consequences. There are, first, negative effects on the young persons who are effectively denied access to modern scientific knowledge. This is, too clearly, a problem already, as educational systems fail to provide excellent science education to many students. But to intentionally link an inferior education in genuine science to the ethnicity and/or cultural background of the students, on the grounds that, for them, the study of modern science is a form of cultural suppression, considerably increases the ethical problem.

Second, there are likely to be negative social consequences, should the CSSE reinterpretation/destruction of the concept of science become fully accepted and standard in science education. Disapprobation of science, of scientific methods of inquiry and the resultant scientific knowledge, is already common in many societies across the globe – public discourse in the United States provides many examples. This is of concern because, in a representative democracy, widespread public disdain for science is easily transmitted into public policy.

Christine L. McCarthy is associate professor in the Schools, Culture, and Society program at the University of Iowa, in Iowa City, Iowa, USA. She received an M.A. degree in Environmental, Population, and Organismic Biology from the University of Colorado and a Ph.D. in Education from The Ohio State University. Her research interests include philosophy of science, philosophy of mind, epistemology, critical thinking, ethics, and the philosophy of John Dewey. She is a coeditor of *The Sage Handbook of Philosophy of Education* (Sage Publications 2010) and author of the chapter *Concepts of Mind* therein.

Chapter 60
Science Education in the Historical Study of the Sciences

Kathryn M. Olesko

60.1 The Historiography of Science Education

Historical scholarship since the 1930s has demonstrated that science education is not merely a minor subfield of historical investigation somewhat akin to institutional history, but is in fact central to understanding the contours of scientific practice, the formation of scientific personae, and ability of the scientific community to reproduce and survive. The historiography of science education to date has highlighted the ways in which educational settings sustain clusters of values, mental habits, and material practices that make possible the epistemological and social dimensions of science, including the transmission and popularization of scientific knowledge; the conduct of teaching and research; the training of recruits; and the public's views on science, including its social, political, cultural, and economic functions and the image of the natural world it conveys.

What occurs *inside* educational settings has much to do with what is *outside* them. The values, habits, and practices of scientific practitioners acquired in training are sometimes drawn from culture at large, as they are when craft or technical practices are adapted to the study of nature. Conversely, the values and habits cultivated in science instruction are part of the socialization of the pupil, and thus, science education participates in the construction of the individual, society, the state, and civil society. In addition, norms of social interaction in educational – and by extension, professional or workplace – settings have been shown to be as important as knowledge transmission in the course of training scientists or educating pupils at all levels of instruction. Crossings between "outside" and "inside" or between science and society provide a way to understand the mutual integration of science and culture, including national goals. Studies of science education have thus

M.R. Matthews (ed.), *International Handbook of Research in History, Philosophy and Science Teaching*, DOI 10.1007/978-94-007-7654-8_60,

demonstrated that the vitality of the sciences and their practices has as much to do with their internal robustness as with their linkages to broader historical contexts, including daily life.

The history of science has reached a point where science pedagogy now has a secure place in understanding the nature of science. Simply put, science cannot exist without institutional and intellectual forms of disseminating knowledge and educating students and practitioners. Yet the historical study of science pedagogy transcends concerns for disciplinary reproduction in the sciences. The histories of science education are now many, and major review articles on the topic have become more common.[1] Historical approaches to the topic, however, are bifurcated into historians of science who view science pedagogy largely (but not entirely) as a problem in disciplinary creation and reproduction and historians of education who view science pedagogy and science popularization more broadly as a means of transferring value from institutional science to the public at large for the purpose of securing social stability, economic well-being, cultural hegemony, or political power (Rudolph 2008).[2] School science, popular science, university science, laboratory science, industrial science, and government science are some of the most salient sites of the many types of science pedagogy that not only sustain the scientific enterprise but also present the public with value-laden options of how to live their lives.[3]

While current scholarship takes into account the wide variety of institutional spaces in which the transmission of scientific know-how, intellectual and manual, occurs, much remains to be done. This essay treats scholarship by historians of science who have studied science education at either institutions of higher learning or sites of professional scientific activity (e.g., postdoctoral training). To a large degree, these studies have focused on the training of practitioners, but they have also considered the broader social, cultural, economic, and political functions of science education in producing secondary school teachers, administrative bureaucrats, and engineers or in realizing the ideological goals of dominant elites, such as the German notion of *Bildung* or the American Cold War ideal of a national security state. After a brief historiographical review, this essay examines four principal loci of historical investigation: scientific textbooks; science pedagogy, or how science is taught and learned; pedagogical practices in the generational reproduction of scientists; and finally the political, social, and economic dimensions of science education.

[1] For overviews of the literature, see Macleod and Moseley (1978), McCulloch (1998), Mody and Kaiser (2007), Olesko (2006), Rudolph (2008), and Simon (2008).

[2] Concerning the transfer of values to the public, Rudolph (2008, p. 65) perceptively argues that the exchange goes both ways and that the boundary between scientific values and nonscientific ones is a zone of conflict worthy of historical investigation. Rudolph's review of the literature on science education and the lay public is exemplary (2008, pp. 69–75).

[3] For representative variety of settings, see Daum (2002), Dennis (1994), Geiger (1998), Holmes (1989), Kohlstedt (2010), Leslie (1993), Nyhart (2002), Olesko (1988), Olesko (1989), Pauly (1991), Rudolph (2002), and Schubring (1989). Studies of science instruction in primary education, secondary education, and the public sphere deserve their own dedicated historiographical reviews along the lines of Rudolph (2008).

It concludes by reflecting on how the emerging area of scholarship known as the history of the senses can be incorporated into the history of science education.[4]

60.1.1 The Early Twentieth Century

Before the 1930s dry-as-dust histories of educational institutions, dating from the late nineteenth to early twentieth centuries, had valorized the training of scientists in the industrialized world without casting a critical eye on the pedagogical process itself. With largely descriptive surveys underpinned by tables and statistics, these studies helped to create founder myths and institutional shrines within specific disciplines that subsequently proved difficult to displace in the historiography of the sciences. These myths helped to entrench a logical positivist historiography by viewing education through the lens of the progress of research. That approach faded in the 1930s when sociologists of knowledge, struck by the contrast between the liberal, rational conception of the individual promised by the Enlightenment and the conformities pressed upon the masses by totalitarian states, began to unpack the relationship between reason, behavior and social norms, and identity formation (Elias 1939; Fleck 1935; Schutz 1932).

Among this generation of sociologists of knowledge, Ludwik Fleck had particularly perspicacious insights into the nature of science learning in the context of what he called the "genesis and development of a scientific fact" – the general idea that facts are not discovered, but are rather made in a process that involved intellectual decisions, institutional practices, and social judgments that are all learned in training. Science education in his view created the mental and social frameworks necessary for the cohesiveness of a scientific community and for the creation and acceptance of new ideas. Education also established links to the past via the "syllabus of formal education" (Fleck 1979, p. 20). Fleck thus embedded the educational processes of socialization and training in broader contexts, claiming that "In science, just as in art and life only that which is true to culture is true to nature" (Fleck 1979, p. 35). Most relevant to this essay, Fleck believed that "initiation into science was based on special methods of teaching" (Fleck 1979, p. 112). But his views on science went largely unnoticed until the translation of his work into English in 1979. By then whatever he could have offered the historical analysis of science education was eclipsed by the popularity of Thomas S. Kuhn's *Structure of Scientific Revolutions* (1962) which, Kuhn later revealed, may in any event have had its origins in Fleck's work. Kuhn, however, quickly forgot he had read Fleck and could later only surmise his indebtedness to him (Kuhn 1979, pp. vii–ix).

---

[4] I thank Michael Matthews, editor of this volume and of *Science & Education*, for permission to reproduce and paraphrase parts of Olesko (2006) in this essay.

60.1.2 The Later Twentieth Century

In the aftermath of the Third Reich and the ideological realignment of postwar educational systems into the Cold War intellectual factories for defense, studies of the social system of science fell into two distinct phases, both of which shaped perceptions of the historical significance of science education. The first, from the end of World War II to roughly the beginning of the tumultuous social and political movements of the 1960s, was marked by an ideological capitulation to a system that placed great faith in science and technology as guarantors of the strength of the nation state, whatever its political orientation. Science education became one means among many for bolstering national security and tipping the global balance of power, as had occurred in the United States, the Soviet Union, and Great Britain and other nations that became members of the nuclear club. It also became a sine qua non for developing states that aspired to become modern. Key concepts defining the social system of science originating in this period tended to follow politics and shielded science from a deeper examination of certain features of its internal operation, including the question of how science was learned in the first place. A prominent example is Polanyi's notion of "tacit knowledge" which rendered ineffable some of the techniques of science as well as the methods of how scientists were trained (Polanyi 1958).

60.1.2.1 The 1960s and 1970s

The 1960s marked the beginning of the second phase when methodological changes in the history of science lifted the veil of secrecy that had hitherto concealed aspects of scientific work, revealing more clearly the interweaving of scientific and social practices. From historians as diverse as Michel Foucault (1966, 1975), Thomas Kuhn (1962) and Jerome Ravetz (1971) came a matrix of fruitful questions about the role of science education in the practical work of science as well as in discipline formation and maintenance.

By viewing scientific education as a process of near totalitarian indoctrination, Kuhn highlighted the powerful role of science pedagogy in transmitting paradigmatic problems, solutions, skills, and other guidelines for scientific practice. Practical activities, including instruction and knowledge production, were united in what Kuhn called normal science, his epithet for everyday scientific practices and beliefs. In his view the external world intervened in scientific practice only during periods of crisis that evolved into paradigm shifts when methods and skills metamorphosed in response to cognitive dissonance (Kuhn 1962).

More sensitive to the nuances of science pedagogy than Kuhn, Ravetz prioritized the social dimensions of instruction over intellectual ones. Training in how to make the kinds of sound judgments that avoided the pitfalls of scientific research (i.e., unsolvable problems and the dead ends of fruitless research trajectories) attracted his attention more than the content of knowledge or the means of its transmission.

Yet Ravetz was also deeply indebted to Polanyi and could not abandon the notion that skills were tacitly learned under the guidance of a master scientific instructor much in the same way that craftsmen learned trade skills. By definition skill learning could not be the object of historical investigation because it was ineffable. Ravetz viewed teaching as an intensely personal process, one so personal that were the precepts of scientific practice made explicit, learning the craft work of science would be irreparably damaged. Despite his insights, his impact on the historical study of science education has remained limited (Ravetz 1971).

Historians of science education may still genuflect to Kuhn, but it was Foucault who most invigorated theoretical discussions of history of science education. His intentionally ambiguous use of the word "discipline" – as conceptual organization but also corporeal training *and* character development – united the social, moral, and intellectual normalizing functions of education (Foucault 1975). Foucault was persistently critical of historians of science for their inability to grasp what was at stake in the construction of scientific regimes. For him the notion of "discipline" encompassed a plethora of minor procedures with major repercussions. Enforced by institutions of higher learning and the legal apparatus, disciplining *made* the modern individual and hence was constitutive of the formation of both modern society and the modern state. In three particular components of disciplining, Foucault discovered, too, the social processes at work in the pedagogic formation of modern scientific disciplines: hierarchical observation, normalizing judgment, and the examination or test (Foucault 1975). Although Foucault's views were not uniformly adopted, historians of science echoed his point of view in their study of systems of examination (Clark 2006, pp. 93–140; Macleod 1982) and in their affirmation of the centrality of teaching to launching and sustaining the disciplines (Pyenson 1978, p. 94). In other respects, however, the views of Kuhn and Foucault were often at odds with what more empirically based studies have demonstrated (Simon 2008, p. 105).

60.1.2.2 The 1980s and Beyond

A third conceptual phase, the focus of this essay, began in the last decades of the twentieth century. This phase was characterized by a deeper examination of the empirical record of science education in local, national, regional, and global contexts; a methodological pluralism that circumscribed the interpretive power of theoretical studies of science education (based nearly exclusively on Kuhn and Foucault) and expanded the role of historical contingencies in the shaping of science and its pedagogical practices; and a recognition that while science education was a subject in its own right, it was also an important site for understanding not only the larger structure and operation of the entire scientific enterprise but also more broadly in the construction of modernity. Consequently the historical study of science education became a window on the larger political, economic, and social environments of which science was a part. Due to the dominance of the military-industrial-university complex in the post-World War II period, the focus of historical studies of science education was largely, but not exclusively, upon the physical sciences.

Historiographical developments since the 1960s have refined the methodologies used to study the trio discipline, pedagogy, and practice. While not abandoning institutional contexts, new approaches have nonetheless gone beyond them. An important fruit of this effort has been the detailed historical examination of the training of neophyte scientific practitioners, which in turn has led to a recasting of how disciplinary history unfolds. Yet the historical significance of pedagogical experiences goes beyond the admittedly artificial confines of disciplinary history to include social, political, cultural, and economic history. These larger contexts have shown how widespread and necessary the framework of support and approbation was (and still is) for science education, dispelling the idea that science education is a self-driven enterprise.

60.2 Scientific Textbooks

The study of scientific textbooks was among the earliest genres in the history of science education. It still remains the most popular. Textbooks are enticing as historical objects of investigation because they present neatly packaged compilations and arrangements of scientific knowledge suited for instruction. They also confound historical investigation because they represent a selective history of their subjects. These contradictory traits led Kuhn (1962) to view them as little more than static moments or paradigms in the history of normal science and so as constraining in their effect upon students. Fleck (1935, 1979), however, created a dynamic conceptual framework that illuminated their role in discipline formation. He viewed textbooks as part of an intellectual continuum, occupying a position between journal and vademecum (handbook) science and popular science. As an intellectual hybrid, textbooks both initiated students to scientific ways of thinking and preserved some contact with ordinary knowledge.

Recent scholarship has cautioned against defining the textbook genre too narrowly, as an organized distillation of the results of research and in contradistinction to scientific popularization. The boundaries between different representations of knowledge now appear more fluid, and the distinction between genres less clear. At the most general level, textbooks are indispensable sources for capturing how thousands of students (and not merely future scientific practitioners) are exposed to science and what image of science they are likely to form. In the mid-1980s, sociologists of knowledge reinforced the association between textbooks and discipline formation by defining disciplines as “knowledge assembled to be taught” (Stichweh 1984, p. 7). Textbooks now are considered integral to understanding not only traditional topics of historical investigation, such as the development of ideas, epistemological choices and debates, the taxonomy of skill-based learning, and even the social dynamics of science such as priority disputes, but also the shifting relationship between science and society and the transnational nature of science (Simon 2011; Vicedo 2012, p. 83).

60.2.1 Textbooks and the History of the Disciplines

A defining feature of historical scholarship on scientific textbooks is its emphasis on discipline formation. Chemistry textbooks have attracted particularly sustained attention in this regard. Hannaway (1975) pioneered this branch of the historical study of science pedagogy in his study of Andreas Libavius's *Alchymia* of 1597. Regarded as the first chemistry textbook, *Alchymia* organized knowledge and united knowledge with practical skills; proffered plans for a "chemical house" or laboratory where hands-on learning would take place; and, in Hannaway's view, offered an alternative to the secretive nature of Paracelsus's alchemy by creating open chemical knowledge. By teasing out *Alchymia*'s long-standing usefulness and popularity across the century after its publication, Hannaway argued that *Alchymia* made vital contributions to intellectual dialogue on the nature of chemistry – quite the opposite of the deadening routine that Kuhn had identified with textbooks.

Historians have since qualified Hannaway's ambitious claims without dismantling its position as a turning point in the history of chemistry textbooks. *Alchymia* spread Paracelsian techniques by incorporating some of them into chemistry – thereby uniting the practical arts with science and academic forms of argument – and so to a limited degree became a textbook that was suited for both university instruction and the needs of the practical arts. According to Powers (2012), Herman Boerhaave (1668–1738) completed the transformation begun by Libavius. Boerhaave took a didactic form of chemistry based on some skills and operations, but lacking in concepts suited for examining the properties of chemical species, and combined it with elements of alchemy, chemically based medicine, and experimental natural philosophy – all of which he believed could fill in the conceptual gaps of a didactic chemistry. Furthermore, according to Powers, the instrumental practices of these latter three subjects (practices Libavius did not fully address) were crucial in shaping the practical side of chemical instruction. The result was Boerhaave's *Elementa Chemiae* which, in 40 editions between 1722 and 1791, set a pedagogical and research agenda for chemistry and defined chemistry as both an academic discipline and a practical art years before Antoine Lavoisier. Powers noted, however, that the assimilation of *techne* into teaching at the University of Leiden was not easily done, but once accomplished, chemical instruction assumed a dual nature as both theoretically and instrumentally based, with each side influencing the other. Thus, both Libavius and Boerhaave used science pedagogy as a platform for defining chemistry as a discipline.

Bensuade-Vincent in her review of textbooks from the chemical revolution (1990) argued that textbooks not only serve as snapshots of a discipline, but they are also essential for understanding the formation of schools, and so they function as tools of training, professionalization, and standardization (Bensuade-Vincent 1990). In this vein Hall (2005) has demonstrated that Lev Landau's and Evgenii Lifschitz's *Course of Theoretical Physics* played a decisive social role in the 1930s and later in shaping a Soviet research school in theoretical physics by framing problems and techniques for solving them that later carried over into research practice. In this way Soviet theoretical physicists could differentiate themselves from other schools, such as Arnold Sommerfeld's (whose German school was also created through a distinctive pedagogy and a defining textbook, *Atomic Structure and Spectral Lines,* which went through several editions during the crucial phase of quantum mechanics in the 1920s). Hence, although some textbooks defined transnational scientific communities, these Soviet and German cases indicate that the social and intellectual training of scientists could very well result in more localized sets of practices.[5]

In some quarters it has become commonplace to define and even to identify a discipline in terms of how it is taught or even represented in textbooks (Simon 2011). Certainly the creative role of textbooks in *helping* to create the disciplines cannot be denied. As textbooks are widely translated, reach transnational audiences, and become the foundation of national examinations in the sciences, the urge to associate them closely with discipline formation is compelling (Simon 2008, 2011). Especially when the creative processes at work in textbook construction, revision, and translation are considered, the ability of textbooks not only to *define* disciplines but also to *reshape* them is incontrovertible. Textbooks are remarkably fluid intellectual products (Bensuade-Vincent et al. 2003; García-Belmar et al. 2005).

Yet there are limitations to this perspective. Chief among is the danger of viewing the evolution of a textbook as teleological – as inevitably and directly reaching the terminus ad quem of a "discipline." That approach creates a deterministic pathway of analysis that could obscure the historical significance of a textbook that goes off the beaten path. Textbooks can be transnational, but they are also historically contingent in both creation and use. They can be universal, but they are also sites of conflict and competition. Arguments over which textbooks to use (or even to create) in science education are instances where there are competing views of reality, interpretation, and method coming to terms with one another. Such arguments could also be indicative of a struggle for scant resources (as when representatives of different approaches compete for the same clientele) or a struggle for prestige (as when scientists define their allegiances through the use of a particular textbook in teaching). These and other adaptations to or constraints of context limit the universal and transnational nature of textbooks. And context, in turn, modulates the degree to which a textbook does or does not contribute to discipline building.

The persistence of local scientific practices (especially industrial ones of relevance to the sciences, such as chemical technologies) that resist incorporation into textbooks, for instance, forestalls their broader recognition and acceptance and makes their adaptation elsewhere difficult if not impossible (Lundgren 2006). Other countertendencies to discipline building include the production of textbooks that challenge what later become dominant approaches (say alternatives to Newtonian physics in the eighteenth and early-nineteenth centuries, including Romantic nature philosophy) (Lind 1993, pp. 278–314). Examining only those textbooks which fed into the dominant tradition would be to represent falsely what historical reality was at the time. Most textbooks also fail to address some of the investigative techniques and skills of scientific practice which are incorporated, instead, into laboratory manuals (Olesko 2005). A textbook may be a partial map to a discipline, but it is not the discipline as a whole.

---

[5] As also demonstrated by Kaiser (2005a), Olesko (1991), and Warwick (2003).

60.2.2 Textbooks and Their Historical Contexts

Textbooks can also be viewed as focal points for many of the historical contingencies that shape both scientific practice and the roles of science and the scientist in society and so carry historical significances that transcend that genre. Their physical dimensions, for instance, are not boundaries that mark the "inside" and "outside" of science but rather can be likened to porous filters that permit the intermixing of several different cultural elements and so have been studied as a part of culture writ large. Recent scholarship has exposed the connections between textbook culture and the constitution of the public sphere; teased out the relationship between textbook production and social structure; and, most importantly, provided strong evidence that the decisive century in textbook culture may not be the nineteenth, when textbook culture matured, but the eighteenth, when textbook culture was just beginning.

A particularly productive locus of scholarship on scientific textbooks has been the team of Bernadette Bensaude-Vincent, Antonio García-Belmar, and José Ramón Bertomeu-Sánchez.[6] Their collective results are the most comprehensive, thorough, and innovative studies to date of the textbook culture in any of the sciences. To their credit they have viewed textbooks as active agents of culture, but not necessarily as carriers or even creators of disciplinary knowledge as early works in the genre, such as Hannaway's (1975), argued. They view textbook writing as a negotiation between author, public, press, and state (García-Belmar and Bertomeu-Sánchez 2004). The richness of their collective findings is in large part of the result of their ability to assemble international teams of scholars whose combined linguistic abilities enable them to examine cultures less well known and to achieve results attainable only through careful comparative histories. Of special note is the team's decision to examine the scientific periphery, including such places as Portugal, Hungary, and the Greek-speaking areas of the Ottoman Empire. Just as earlier works on science pedagogy during the Cold War adapted to a culture of secrecy and national security, this team's work on textbooks shows the impact of ongoing European integration.

Although their collective approach is largely empirical, their findings nonetheless mesh with earlier theoretical writings on science pedagogy. Of relevance to their project is Fleck's depiction of the historical role of publishing in sustaining science pedagogy where published knowledge becomes a "part of the social forces which form concepts and create habits of thought" determining "what cannot be thought in any other way" (Fleck 1979, p. 37). His account of the viability of scientific knowledge necessitates a reading public that takes an active part in the public sphere where discussions concerning the relevance and interpretation of scientific knowledge occur. So when Antoine Lavoisier's chemistry entered Portugal by way of Vicente Coelho Seabra's *Elementos de Chimica* around 1790, the absence of a local chemical community and a weak public sphere, constrained by the inquisition

---

[6] A partial list of their projects includes Bensuade-Vincent (2006), Bensuade-Vincent et al. (2002), Bensuade-Vincent et al. (2003), García-Belmar & Bertomeu-Sánchez (2004), García-Belmar et al. (2005), and Lundgren and Bensuade-Vincent (2000).

despite the expansion of print culture under Maria I (1777–1792), were reasons why Seabra's textbook was not adopted (Carniero et al. 2006).

Likewise in Russia the cumulative effect of the Church's monopoly on printing was to stunt the growth of a healthy public sphere where the free exchange of information could take place, thereby also restricting the growth of scientific communities (Gouzevitch 2006). In the Greek-speaking regions of the Ottoman Empire along the western end of the Mediterranean, the dominating presence of merchant elites meant that practical knowledge, conversions (weights and measures, coinage, and the like), and navigational issues were more important than Isaac Newton's *Principia*, so the former dominated textbooks in the physical sciences (Petrou 2006; Patiniotis 2006). Yet in each of these cases, the limited audience reached by textbooks did not diminish their roles in creating conditions conducive to the future growth of the public sphere: to wit, they promoted the standardization of language, vocabulary, scientific idiom, and alphabet that would eventually promote a larger reading public and audience for the sciences.

Publication patterns in scientific textbooks thus help in understanding the social structure and technical and scientific interests of the region over which they are found. The strong elite merchant class in the Ottoman Empire accounts for Greek translations of textbooks on practical geometry, geography, and commerce (all were useful for trade) and the relative paucity of textbooks on physics and chemistry, which carried little of significance for merchants. Conversely, as Patiniotis (2006) has observed, the absence of social support can doom a branch of knowledge. Textbook distribution reflects the balance of power among elites, as it did in the Ottoman Empire where the laws of the marketplace were more important than the laws of nature.

Characterized by discipline building, university history, the reform and extension of the secondary school, and the professionalization of the career of the scientist, the nineteenth century is often considered the defining moment in the modern social and institutional forms of science education. Recent studies of scientific textbooks demonstrate, however, that the eighteenth century may actually have more to offer us in terms of *why* (rather than *how*) these changes took place. As Patiniotis (2006) has pointed out, the word *textbook* was coined in the eighteenth century. The protracted shift from Aristotelian scholarship to more recent knowledge, as took place in Portugal under the *estrangeirados* during a period of enlightened educational reform, suggests that the intellectual dynamics of textbook organization in the eighteenth century may have been more problematic and difficult than they were in the nineteenth. Likewise the rapid intellectual shift in those areas under Napoleonic rule, such as northern Italy in 1796–1797 where the new French chemistry was established by law under public educational reform acts (Seligardi 2006), calls to mind the popular and social support required to make the shift permanent.

60.3 Science Pedagogy

Yet textbooks have their shortcomings as historical sources: they cannot reveal what went on the classroom, and they provide little information on how students learned and what their experiences meant to them. Since the late twentieth century, historians of science have turned to other types of documents in an attempt to understand the behind-the-scenes activity of teaching and learning in the sciences. Lecture notes, problem sets, student notebooks, examinations, laboratory exercises, instructional instrumentation, and multiple varieties of unpublished, duplicated materials have become privileged ways of reconstructing what went on in the seminar, lecture hall, and practicum. When supplemented by complementary materials, some published and some not (such as personal correspondence; diaries; autobiographies; laboratory notebooks or simply notebooks; and published versions of lectures, often straight from raw notes), the resulting historical scholarship reached even beyond a deeper understanding of science instruction to reveal how dependent all aspects of science as a human activity were upon educational processes. From primary education to the professional level of postdoctoral fellowships, apprenticeships, and the acculturation of mature researchers to new institutional settings, pedagogy played a part.

To confine science education to the transmission of knowledge or to the internal practices of the scientific community, then, is to mischaracterize the historical roles of science pedagogy. Science education has played a role in forming value systems; the scientific self (mentally, bodily, behaviorally, sensory, affectively, emotionally); social norms, including where in the social hierarchy different kinds of sciences fell; gender relations, both in- and outside the sciences; the power relations that determined the relative position of science and scientists vis-à-vis the state, society, and the economy; the cultural function of the sciences; and, finally, the role and perception of rationality in modernity. Science pedagogy thus has become the fulcrum which rests some of the most important dimensions of modernity. With what regard science education was held and why, as well as how much support that it garnered from the state and society, have become key historical questions in the study of both local manifestations and larger systems of science instruction.[7]

60.3.1 The Pedagogical Dimensions of Science Instruction

An early focus in the study of science pedagogy was the introductory science course offered in colleges and universities. Although it goes without saying that introductory courses had to be carefully framed to both attract and retain recruits in the sciences, only slowly did historians realize that their constitution demanded historical explanation. Geison (1978), Holmes (1989), and Olesko (1991) in their studies of, respectively, the physiologist Michael Forster at Cambridge, the chemist Justus Liebig at Giessen, and the physicist Franz Neumann at Königsberg are three early examples of how student needs shaped the tenor and texture of introductory courses. The pedagogical strategies of these scientists were instrumental not only in

---

[7] Major studies that contributed to the broader significance of science pedagogy include Clark (2006), Gooday (1990, 2005), Gusterson (2005), Hentschel (2002), Josefowicz (2005), Kaiser (2005a, b), Olesko (1991, 2005), Pyenson (1983), Rossiter (1982, 1995, 2012), Schubring (1989), Traweek (1988, 2005), and Warwick (2003).

accommodating their student clientele but also in preparing them for advanced exercises and eventually research.

The instructional successes in each of these cases were dependent upon intimate knowledge of their students' prior preparation, a judicious integration of the techniques of research into teaching, and a willingness to deploy pedagogical techniques that both worked and accommodated student needs. Effective teaching also depended upon coordinating the introductory science course with secondary school science instruction. Foster's evolutionary approach to biology and physiology challenged the former anatomical bias in English physiology; Neumann's instrumental use of mechanics brought astronomical techniques into the core of physics teaching; and Neumann's and Liebig's emphasis on instrumental and error analysis promoted more rigorous standards of precision in physical and chemical investigations (Geison 1978; Holmes 1989; Olesko 1991).

Using the introductory science course as representative of science teaching and learning, though, is a bit like claiming that a textbook represents what is taught and learned. In both cases access to what actually went on in the classroom is limited. The sources available to Olesko in her study of Neumann's seminar, though, overcame that limitation. With seminar reports, seminar exercises, correspondence, lecture notes, and student problem sets, she was able to render how both teaching and learning transpired in the seminar. The results were unexpected. Rather than inculcating only the mathematical techniques of theoretical physics, Neumann concentrated instead on teaching his students the methods of an exact experimental physics: to wit, the determination of both the constant and accidental (random) errors of an experiment, the latter by the method of least squares. Bessel's exemplary seconds-pendulum investigation, undertaken for the determination of an official unit of length in Prussia, served as a model for the precision-measuring exercises of the seminar (Olesko 1991) (Fig. 60.1).

The cumulative effects of doing these exercises were transformative for students. Their investigations demonstrated how they acquired what Fleck called the professional habits needed to become a "trained person" (Fleck 1979, pp. 89–90). But something more happened. The emphasis on the precision and reliability of their data, the determination of constant and accidental errors, and the marginalization of techniques of approximation meant that there was an "epistemological and technical concern for certainty that at times bordered on obsession" (Olesko 1991, p. 17). That obsession, which Olesko called the "ethos of exactitude," failed to sensitize students to when the quest for epistemological certainty should end. The ethos became an ethic in the sense that it "guided professional actions and decisions by providing the ways and means of separating right from wrong, truth from error, and the even the called from the damned. It helped to define professional identities, structure investigative strategies, and identify significant problems" (Olesko 1991, p. 450). While this ethos thus played a determinative role in shaping the professional behavior of Königsberg seminar students, it also created psychological limitations that were often crippling: the quest for absolute precision was in the end an illusion, one that sometimes prevented them from seeing more pragmatic, and quicker, solutions to the problem at hand.

Fig. 60.1 Gottlieb Anton Müttrich (1833–1904), notebook from the physical division of Franz Neumann's seminar at the University of Königsberg, 1854. In his determination of the horizontal component of the earth's magnetism, Müttrich applies the method of least squares, a hallmark technique of the seminar (Source: Arbeiten der physik. Abteilung des mathem. Physikalischen Seminars der Königl. Universität in Königsberg 1854–55. Heft 1 [21945/55]. Abt. Va Rep. 11 Planck 1836/26. Max Planck Gesellschaft Archiv, Berlin)

Like the Königsberg case, other detailed studies of science pedagogy have demonstrated how intensely local some practices were. Warwick's history of the Cambridge Mathematical Tripos, an examination on analytical mathematical methods rooted in Newtonian mechanics, rested on actual tests (but not on the students' answers, which would have revealed how students performed) and other sources that illuminated the process of learning, including the notes of the coaches who offered preparatory training for the test. He concluded that coaches developed such distinctive solutions to problems that when they were applied outside of the Tripos setting, the Cambridge connection was immediately recognized. These techniques were designed to enable the virtuoso performance necessary for scoring high enough on the examination to attain the coveted rank of Wrangler. But at the same time, they restricted analytical solutions to closed algebraic expressions and eliminated infinite series or approximate solutions. The ability to engage in research was not the goal of instruction, yet the impact of these techniques upon practice in physics was profound and long lasting. Of note, James Clerk Maxwell's *Treatise on Electricity and Magnetism* (1873) was not a response to the British Association for the Advancement of Science's study of a suitable electrical metrology (as had so often been assumed), but rather an attempt to resolve pedagogical issues left unsettled when the Tripos incorporated electromagnetic theory in 1868 (Warwick 2003).

The maintenance of the Cambridge coaching system relied on forms of sociability that not only mitigated some of the intense pressures of the examination but that also guaranteed the type of intellectual self-identification associated with a scientific school: face-to-face interaction, bonding with the coach, and small-group learning. This sociability was certainly similar to that attained at Königsberg, but the results were different. Analytical virtuosity was the goal at Cambridge; in Königsberg, competency to pass the state examination for secondary school teachers. At Cambridge the Tripos was for undergraduates, was not in service of a profession, and was part of an intensely local culture. At Königsberg, by contrast, the state examination was for graduate students, was designed to certify the suitability of students who wished to teach mathematics or science in secondary schools, and was administered by academics for the entire state.

Similar to the nineteenth-century examples of Cambridge and Königsberg was the twentieth-century implementation of the newly created Feynman diagrams as a quick way to train physicists, the largest group in the postwar glut of science students. Feynman diagrams were in this sense created to accommodate a particular student clientele. This example demonstrates how a technique that began as a *pedagogical* device ended up as a *standard* tool for solving particular kinds of problems in quantum electrodynamics. In other words, a pedagogical device became a practice not only in the field for which it was created but also in nuclear physics, particle physics, and various forms of experimental physics. Moreover, this new calculational and visual tool "transform[ed] the way physicists saw the world" and eased the conceptual difficulties in teaching quantum electrodynamics (Kaiser 2005c, p. 4). Although the population that used Feynman diagrams was composed mostly of graduate students, the physicists who found them useful constituted a community that recognized the diagram's ability to solve certain problems quickly. Feynman diagrams are thus an example of a pedagogical innovation that was created to accommodate a large student clientele but also became a means to ease the computational tasks in a growing field of science (Kaiser 2005a; Kaiser 2005c) (Fig. 60.2).

60.3.2 Science Pedagogy as Learning by Doing

While much of the historical literature on science pedagogy has focused on how science is *taught,* a small but growing body of scholarship has examined how science is *learned.* The methodological challenges of studying the latter are considerable, for the historian must find sources – notebooks, correspondence, and the like – that reveal the experiences, values, and attitudes of students as they make the transition from neophyte to practitioner. How brightly historians have been able to shed light on what transpired in exercises has depended upon available sources, not only written records of laboratory exercises but also instruments used for them. Success has been mixed, and much has to be inferred. Holmes' (1989) study of the relationship between teaching and research in Justus Liebig's Giessen chemistry laboratory relied on traces of laboratory teaching in either Liebig's publications or those of his students, and hence, his findings were necessarily incomplete. Liebig's concerted efforts to transform chemistry instruction through the introduction of the components of research procedures as smaller manageable exercises can only be inferred indirectly.

To varying degrees historians have been able to ascertain the exact exercises assigned to students and to assess their ability to complete them, but largely only for the case of physics. In the United States, Great Britain, and Germany, laboratory instruction began between the 1860s and 1880s, although, in Germany, smaller private instrument collections enabled hands-on learning decades earlier. But here too the results are skewed toward what documentary evidence is available. What is known about British laboratory practices also comes from comments in scientific publications. Far better reconstructed from printed sources are the reasons why such instruction succeeded in the first place and how that instruction was sustained. In Britain the factors contributing to the introduction of precise measuring methods into teaching laboratories between 1865 and 1885 were the development of precise measuring methods in the committees of the British Association for the Advancement of Science (e.g., for electrical standards), the inauguration of a student laboratory at Glasgow by William Thomson in 1855, and the example of professional physicists using precise measurements. Precision in measurement as a part of instruction was legitimated by the presence of a type of liberal education that emphasized rational and accurate reasoning, especially for future teachers; by the need to demarcate scientific methods from craft-based procedures; and by the association of precision measurement with economic production, especially in the telegraphic industry (Gooday 1990).

Industrial connections and lofty ideological goals were less in evidence in the United States when student laboratory instruction started after 1850. Here findings have relied on manuscript sources, laboratory manuals, and the printed record. Laboratory exercises became especially popular after the publication of Edward C. Pickering's *Elements of Physical Manipulation* (1873–1876), a manual adopted by most universities and colleges having the necessary space and instruments for such instruction (Kremer 2011). Laboratory instruction and instrument production were robust and flexible enough in America to accommodate student exercises in the new field of spectroscopy, which relied on precision gratings of sufficient resolution to give sufficiently differentiated visual results for instructional purposes and to do so at affordable cost (Hentschel 2002).

The development of laboratory instruction and the construction of university laboratories in Germany arose in response to student needs around 1870, although private collections afforded the opportunity to offer exercises earlier in the century, especially in Germany's numerous science seminars (Cahan 1985; Olesko 1991; Schubring 1989). For the German case, the archival record is rich and rewarding. Not only do historians have access to student notebooks, student exercises, lecture notes, and annual reports on teaching; they also have, in some cases, notebooks depicting the genesis of laboratory exercises. Such is the case for the most well-known and popular of laboratory manuals in physics, Friedrich Kohlrausch's *Leitfaden der praktischen Physik* (1870), which by 1996 went through 24 editions. Kohlrausch, who became an assistant to the physicist Wilhelm Weber at the University of Göttingen in 1866, worked for 4 years exploring which physical exercises worked best especially for beginning students. He left behind meticulous records of his experiences with exercises, as well as of student responses to them. Historical documents of this type, while rare, provide unsurpassed insight into how hands-on learning took shape, as well as student reactions to it (Olesko 2005) (Fig. 60.3).

60.4 Generational Reproduction

Generational reproduction is a complex issue in science pedagogy because it straddles traditional and nontraditional pedagogical settings. The reproduction of scientists is in one sense the direct result of the efficacy of science pedagogy. Yet that reproduction is also dependent upon robust pedagogical practices at the postgraduate institutions. At the simplest level, handbooks – compilations, distillations, and novel organization presentations of "what everyone knows" – are examples of higher-level pedagogies that sustain scientific practice in professional settings (Gordin 2005). At the next level, bureaucracies like standards institutions have to develop and deploy pedagogy simply to accomplish their mission. For instance, at Germany's Imperial

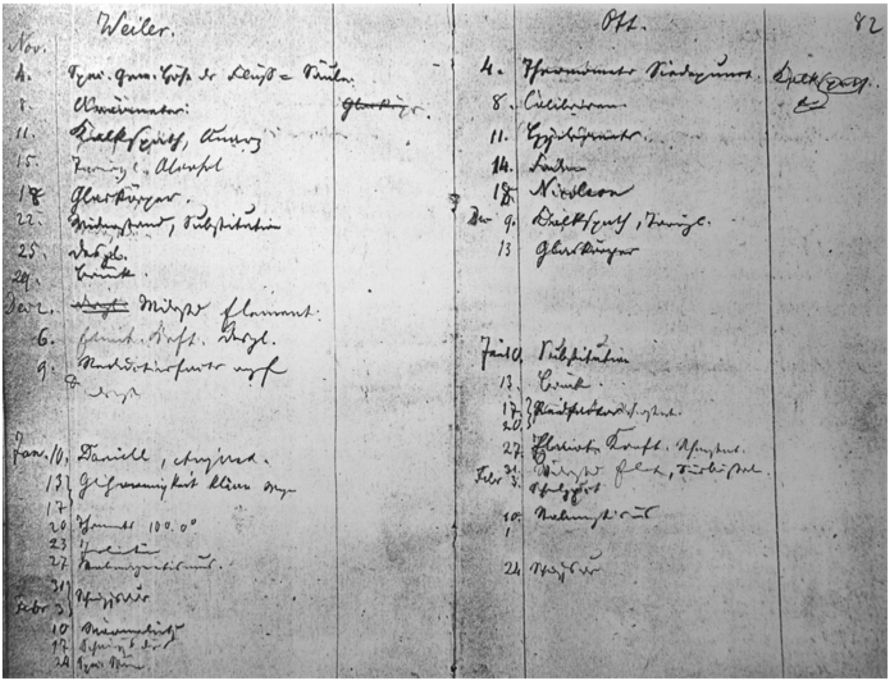

Fig. 60.3 Friedrich Kohlrausch's journal of laboratory exercises assigned to two students, November 1871–February 1872 (Source: Friedrich Kohlrausch Nachlass, Tagebuch Nr. 2504, Deutsches Museum Archiv, München)

Institute of Physics and Technology (established 1887), young physicists fresh from their doctorate had to acculturate themselves by learning the institutional norms of a bureaucracy whose purpose was both fundamental (as in standards determination) and novel (as in measuring black body radiation) (Cahan 1989). Indeed standards institutions around the world rely on higher forms of pedagogy not only for their own practitioners at home but also in order to normalize metrologies across the globe.

Such strategic interventions of science pedagogy have become apparent especially in instances of scientific disputes over the interpretation of data or when analytical representations fail to mesh. As Gooday has shown, pursuing solutions in the manner of the Mathematical Tripos could persist years after taking the examination, resulting in conflict with other professional norms. That's what happened to John Hopkinson who, in posing a solution to a particular electromagnetic problem using Cambridge techniques, clashed with a well-entrenched engineering graphical tradition. In the end Hopkinson accommodated the analytical and practical-graphical traditions, but his story is one that underscores the persistence of science pedagogy in making sense of the world (Gooday 2005, p. 142).

A special case of the strategic role of science pedagogy is found in the realm of nuclear weapons scientists. From 1945 to 1963 when the Limited Test Ban Treaty was approved and nuclear bomb testing went underground, nuclear weapons scientists enjoyed what Gusterson has called the "charismatic" era characterized by high levels of innovation and guidance from physicists whose experience with testing was indispensable for training new recruits in the ways and means of aboveground testing. In the 1970s and 1980s, however, routinization set in, with the result that innovation slowed, bureaucratic hardening occurred, and individual contributions to the effort were small. By the 1993 ban on all testing, experienced nuclear scientists retired; a new generation of scientists came on board to maintain devices they could not test in reality, and virtual computerized testing replaced real-life experiences with the bomb. Less and less knowledge and know-how about nuclear bombs were passed down generation to generation, resulting in an "involuted pedagogy of diminishing returns" (Gusterson 2005). In other words, the absence of real-life exercises (in bomb testing) means that the teachers (older nuclear scientists) could not train students (newer nuclear scientists) in how to use a test as a feedback mechanism to improve a nuclear weapon. In this case, generational reproduction did not so much as fail as wither away.

Yet perhaps there is no more important issue in the realm of generation reproduction than why women are so poorly represented among the practitioners of certain sciences, especially the so-called "hard" sciences. The gender implications and consequences of science pedagogy are critical problems of its history that beg for deeper analysis. As Rossiter (1982, 1995, 2012) has argued for the American case, women's gains in the scientific professions after initial marginalization and continued second-class status after World War II were ones that took place in the safe haven of women's colleges, through activism and organization, by piggybacking on the women's movement, and eventually favorable federal legislation. At the same time, however, educational benefits like the G.I. Bill of 1944 (and later amendments), the National Defense Education Act of 1958, the National Defense Student Loan program, and other Cold War measures to improve American standing in the sciences resulted in the further masculinization of science education at coed institutions.

In both science education and professional settings where postdoctoral training and professional grooming took place, institutionalized science pedagogy did more injustice than good for women scientists through its perpetuation and legitimation of sexism and other discriminatory practices. In addition systems of scientific training produced a gendered hierarchy of fields where the most impervious to allowing women entry were the hard core sciences. Traweek (1988) has demonstrated how training in high-energy particle physics promulgated gendered norms that worked against the incorporation of women. Over the long term, then, science pedagogy replicated the classical gender hierarchy of modernity.

60.5 The Historical Contexts of Science Education

As a disciplinary practice that often finds itself nestled closely to other branches of science and technology studies, the history of science often neglects, ironically, larger historical contexts as a venue for understanding the past. The result for the history of science education is a tendency to view key elements as static categories: discipline, pedagogy, practice, persona, textbook, and other units of analysis tend to acquire universal dimensions faster than they are understood as categories shaped by historical contingencies that change them over time. As a category of *historical* analysis, science pedagogy thus must be viewed from frameworks larger than either disciplinary or institutional history. The problem is to determine how large that framework should be and what factors are important within it.

For instance, the long-term transition from Aristotelianism to natural philosophy can only be understood by looking at what transpired in educational institutions, but to fully understand that transition, other factors such as the intellectual predilections and activities of religious orders have to be taken into account. Key agents in bringing about that transition were the Jesuits who, through teaching and textbook writing, were instrumental in institutionalizing newer frameworks for learning such as Cartesianism, Newtonianism, and, by the eighteenth century, hands-on learning (Brockliss 2006; Feingold 2003). At a later time, Boerhaave's *Elementa Chemiae* took shape within and absorbed the values of the local context of Leiden's religious, medical, and commercial cultures (Powers 2012). Great Britain's social transformation in the wake of industrialization played directly into Forster's innovations, which were implemented when Cambridge education became accessible to a broader socioeconomic clientele (Geison 1978).

In nineteenth-century Germany where mathematics had political value before it had economic currency, intimate forms of seminar instruction instilled in secondary school science teachers a belief in the powerful role of pure mathematics in interpreting physical reality, a perspective their students carried with them to the university (Pyenson 1977, 1979, 1983). Liebig and Neumann trained students for whom state qualifying examinations for secondary school teaching offered the possibility of upward social mobility and greater economic security (Holmes 1989; Olesko 1991).

Foucault thought that the problem of determining the relations of physics "with the political and economic structure of society" was to pose "an excessively complicated question" (Rabinow 1984, p. 51). Studies of physics pedagogy have nonetheless demonstrated a tightly woven connection between abstract knowledge and social norms and values. Warwick turned his study of the Cambridge Mathematical Tripos into a revealing window on Victorian culture by demonstrating how both mind and body were implicated in scientific and mathematical training. Coaching for the Tripos built character and cultivated the values of the Victorian gentleman. Public events surrounding the Tripos were filled with stress and sweat, ritual, and, for the highest-scoring Wranglers, an earned social status associated with merit (Warwick 2003).

Finally, a historically contextualized view of study of science pedagogy offers an unparalleled opportunity to examine the political dimensions, broadly conceived, of science education. Foucault is widely cited for his advocacy of viewing education as a political process: teachers, who controlled classroom disorder and reported on individual performance, were a strategic professional group whose members were the architects of power relations that both defined and disciplined the individual (Foucault 1975). But this focus on disciplining the subject has tended to ignore the degree to which individual agency was circumscribed by the systems and arrangements that make successful science education possible. Consider the nuclear scientists studied by Gusterson (1996). They learned while working in a nuclear weapons laboratory to create divided selves: a self that during the day created and maintained weapons of mass destruction and a self that on evenings and weekends cordoned off the workaday world in secrecy and silence. The history of science pedagogy is thus not only about understanding the transmission of knowledge and generational reproduction: it is more importantly about pedagogy as a moral and political practice where the examination of textbooks, pedagogical techniques, and institutions is part of understanding the structure of power (Giroux 2011), gender relations (Traweek 1988), civil society (Nyhart 2002), and other dimensions of extra-scientific contexts.

60.6 On the Horizon: The History of the Senses

Intellectual flexibility is a prime desideratum for the future of studies of science education: first, in order to make connections to new areas in historical scholarship and, second, in order to begin to analyze what is emerging as the next phase of science education in the early twenty-first century. Two developments – one historiographical and three contextual – loom large as challenges in writing the history of science pedagogy: the history of the senses, the emergence of massive open online courses (MOOCs), the corporatization of the university, and the growing number of technical professionals who bypass formal modes of science instruction en route to positions in the information technology and other economic sectors relying on scientific and technical knowledge. The controversies erupting over the latter three issues are fascinating (especially in the policy realm) and certainly worthy of study; but it is still too early to discern how they fit overall in the history of science education.

Nevertheless, these changes in the form and manner of science education at the beginning of the twenty-first century are designed to assist students where they need help most: in the mastery of foundational concepts. Scientists and policy makers argue that in the "learning science revolutions," training the eye is essential: "Visual representations are crucial to conceptualizing and communicating science, but students often have difficulty interpreting the models, simulations and graphs that are key to attaining a true understanding of science domains (Singer and Bonvillian 2013, p. 1359)." It seems appropriate then to conclude this essay with an examination of how the history of the senses can be incorporated into the history of science education as a tool of analysis as science instruction takes its next turn.

60.6.1 Integrating the History of the Senses

To a degree historians of science have taken the senses, especially vision, into account in their examination of science education. Most of these studies have focused on instruction in the life sciences, but the recognition that new printing techniques in the nineteenth century transformed textbooks has renewed the interest of historians of science in the role of vision more broadly in science instruction.[8] In addition to vision, hearing and touch are central to science learning, yet these have scarcely been studied and perhaps with good cause. Ideological frameworks, for one, make it difficult to isolate the historical roles of the senses. Karl Marx, among others, held that because the senses were alienated from the individual under capitalism, their history was impossible to write. Practical concerns too have impeded an examination of the senses in history. General historians have acknowledged over and over again the difficulties in writing the history of the senses even as they have maintained that cultural conditioning, which varies over time and across space, determines how individuals and groups deploy their senses (Jay 2011).

Science education is not only one of the strongest contributors to that cultural conditioning: science also cannot exist without sensory training, which in turn is a foundation for scientific judgment. Sharpening the senses to the point of achieving a disciplined focus (of several types) is a process that takes place both in science education and the practice of science. How science instruction enabled students to achieve focus is only beginning to be understood. Boerhaave, for instance, considered it essential to train students in the management of sensory data and for that purpose drew upon more general medieval pedagogical methods that fostered concentrated logical thinking. The new public course on instruments that he introduced in 1718 deliberately linked empirical information (the student's sensory perceptions) to chemical theory, trained students to interpret phenomena according to the instruments that measured their qualities (as in using Fahrenheit's thermometer to measure warmth), and educated the senses by disciplining them. His course on instruments thus complemented his course on chemical theory where the objective was to train reasoning processes (Powers 2012). Yet even as science education transformed the senses, the senses have a history of their own outside scientific contexts.

A transition from aural culture to an ocular one occurred in the passage from the eighteenth to the nineteenth centuries, opening the way for what both contemporaries and historians have called *Anschauungsunterricht* – a type of instruction that enables students both to visualize things and to interpret visual images. This passage entailed the cultivation of more impersonal forms of perception when abstract forms of representation replaced mimetic ones as the "culture of the diagram" replaced copying nature (Bender and Marrinan 2010). Moreover, visual learning expanded in the nineteenth century with the introduction of photographs, charts, spectroscopy, graphs, and X-rays. These instrument-mediated images revealed patterns, as in spectroscopy, that were typical of some aspect of nature (the wavelength patterns of elements) but also mysterious as to what they signified beyond a characteristic pattern. Spectral patterns were difficult to interpret, and so the student's perceptual apparatus had to be formally trained (Hentschel 2002, pp. 368–385). In the twentieth century, image-based science exploded to include electron microscopy, moving

---

[8] See Anderson and Dietrich (2012), Bucchi (1998), Dolan (1998), Hentschel (2002), and Lawrence (1993).

images, and digital imagery. Concomitantly, images transformed textbooks to the point where "visual literacy" became essential both for science learning and as preparation for scientific research (Anderson and Dietrich 2012, p. 2).

60.6.2 Fleck and the Senses in Science Education

How might historians of science education take into account the history of the senses? Fleck's work (1979) could with profit be used here. By isolating three elements of learning that reshape (and so educate) the prospective knower – experience, cognition, and sensation – Fleck offers a way to view science pedagogy as a process that transforms science students into something they are not. The first, experience, concerns the formation of scientific behaviors like the acquisition of skills through observation and experiment and the ability to think scientifically, both of which Fleck claims "cannot be regulated by formal logic" (Fleck 1979, p. 10). What is seen in the form of "words and ideas," he warns, is merely the "phonetic and mental equivalents of the experience coinciding with them." They are merely symbols (p. 27).

Fleck challenges us to view the past of science education differently by replacing our rapt concern for the transmission of knowledge with a fresh look at the behavioral and psychological transformations of the science learner. Experience, sensation, and cognition are all socialized by training, a process he describes as a transformation of the senses: the "slow and laborious revelation and awareness of what 'one actually sees' or *the gaining of experience*" (Fleck 1979, p. 89). Experience thus reshapes not only our minds but also our bodies. Sharpened vision – the ability to identify phenomena, for instance – is indicative of a state of "readiness for directed perception" (p. 92). In a similar fashion, he interprets cognition as a social activity ("the most socially conditioned activity of man"), making knowledge "the paramount social creation" (p. 42). Cognition can, in fact, only be understood according to Fleck as a deeply historical and contextual process that renders the mind nearly one with the beliefs of others around it. So associations between knowledge and value (say when sickness is linked to sin) can only be explained through the lens of cultural history.

Taken together, experience, sensation, and cognition form the core of the professional habits that a scientist exercises day in and day out. They are the foundation of a "collective psychology" (p. 89) transmitted through education which keeps a scientist within the cognitive framework of his or her community. The main characteristic of a thought style is that through it a trained scientist progresses nearly automatically from a vague perception to a stylized and visual one "with corresponding mental and objective assimilation of what has been so perceived" (p. 95).

What makes Fleck's analysis of scientific training useful for the historical study of science pedagogy is its ability to account not only for *learning* science but also for *becoming* a scientist, a process that entails both mental and sensory transformations. Although the strength of a thought collective depends on the existence of active science pedagogies that can carry the thought style from one generation to the next (Fleck 1979, p. 39), Fleck believed that education, although a constraint that both compelled the learner to see only in a certain way, was also pliable enough to allow for the recognition of experiences that resisted their automatic inclusion in a community thought collective. In this way the learner could also become the creative scientist. Indeed he argued that the inability to recognize resistances was the mark of the "inexperienced individual" who "merely learns but does not discern" (p. 95).

Kathryn M. Olesko is an associate professor in the Department of History and the Program in Science, Technology, and International Affairs at Georgetown University where she has also held several administrative positions. She majored in physics and mathematics at Cornell University and then took her doctorate there in the history of science. She is the author of *Physics as a Calling* (1991), the forthcoming *Why Prussians Measured: The Myth of Precision, 1648–1947,* and articles on the history of science. For 11 years she was the editor of the History of Science Society's annual thematic volume, *Osiris*, which she transformed into a forum for mediating the history of science and "mainstream" history. Her interest in the history of science education, which spans her entire career, has focused especially on studies of identity formation in the sciences and on the moral, professional, and epistemological roles of measurement in both science education and professional practice. She is now engaged in the history of measurement and an interdisciplinary historical study of water management in Prussia. Her honors include several fellowships from the National Endowment for the Humanities and the National Science Foundation, short- and long-term appointments as fellow at the Max Planck Institute for the History of Science in Berlin, and the Dibner Distinguished Fellowship at The Huntington Library. In 1998 she was elected a fellow of the American Association for the Advancement of Science for her "contributions to scholarship and teaching in the history of science and for leadership in the History of Science Society and the AAAS."

Chapter 61
Nature of Science in the Science Curriculum and in Teacher Education Programs in the United States

William F. McComas

61.1 Introduction

In the past 50 years, advocacy for and scholarship in nature of science (NOS)/ history and philosophy of science (HPS) in school science has grown from a few scattered references in the science education literature to a veritable flood of support for, interest in, and research in the field.

A single definition of NOS shared by the majority of science educators would be difficult to find, but many would agree that NOS is the area of study in which students learn how science functions, how knowledge is generated and tested, and how scientists do what scientists do. McComas and colleagues (1998, p. 4) suggest that:

> The nature of science is a fertile hybrid arena which blends aspects of various social studies of science including the history, sociology, and philosophy of science combined with research from the cognitive sciences such as psychology into a rich description of what science is, how it works, how scientists operate as a social group and how society itself both directs and reacts to scientific endeavors. The intersection of the various social studies of science is where the richest view of science is revealed for those who have but a single opportunity [such as the case in school settings] to take in the scenery.

Just as there is a lack of complete agreement on the definition of nature of science, the name itself has engendered some debate. Some scholars suggest that it would be best to call this domain nature of science studies, history and philosophy of science, ideas about science, nature of sciences, nature of scientific knowledge, and views on the nature of science, among others. Of course each of these labels has some advantage over the others and is usually preferred by one group or another, typically for philosophical reasons. However, given the extent of scholarship associated with the NOS label and references to it, that will be the term used throughout this chapter.

61.2 The Context of Education in the United States: An Overview

To fully appreciate this report on NOS in the United States, one must recognize the unique way in which education is organized and governed in the nation. At the founding of the republic in the mid-1700s, the original 13 governing entities coalesced into a nation. This new nation had two axes of command and control; the federal (or national) government reserved some powers for itself (defense and diplomacy as examples), and other responsibilities (education, for instance) remained in control of the states. In the United States, education is frequently mentioned as the quintessential *states' rights* issue. In many ways the individual US states such as New York and California function like independent nations; this is particularly true with respect to education.

What has evolved in the United States is a blend of laws, policies, governing traditions, and educational systems that have much in common but leave the ultimate control for schooling to the state rather than federal government. This is a unique situation, with Germany and perhaps only a few other nations sharing such a decentralized system. Each state, therefore, has full responsibility for teacher licensure, achievement testing, the establishment and maintenance of an education bureaucracy, school funding, and the development of educational goals and standards.

The US federal government, generally through the Department of Education (equivalent to the Ministry of Education in other countries), provides some guidance and encourages specific policies by commissioning studies and rewarding states through monetary support (or the threat to withhold such support). The US Congress is also involved in education with its mandate to produce a periodic "report card" on the education situation across the nation through the National Assessment of Educational Progress (NAEP). While it may be useful to talk about education in the United States, overarching statements about the nation as a whole are difficult to make with any assurance; we must look widely and infer liberally.

However, as we will see, the first decades of the twenty-first century have seen a gradual loosening of the states' formally tight grip on education policy with new sets of goals for school science under development by broad groups with representatives from the science and education communities with funding from public and private entities. Soon, virtually all of the US states will adopt what is called *The Next Generation Science Standards (NGSS)*. This is a major change in the educational governance in the United States with vast implications for assessment, teacher preparation, curriculum development, and classroom practice.

61.3 NOS in the Schools of the United States: Some Historical Perspective

There is no single moment when NOS and related ideas entered the educational area, but more than 150 years ago, the Duke of Argyll in his Presidential Address to the British Association for the Advancement of Science stated that "What we want in the teaching of the young is not so much the mere results as the methods and, above all, the history of science" (in Matthews 1994, p. 11). This may be among the first suggestions that an element of what is now called *nature of science* should be part of the school science curriculum.

A century later this view crossed the Atlantic Ocean to the United States, where the Educational Policies Commission *Report on Education for All American Youth* raised the promise of the use of NOS (1944, p. 132) by stating:

> These scientists are thought of as living men [sic], facing difficult problems to which they do not know the answers, and confronting many obstacles rooted in ignorance and prejudice. In imagination, the students watch the scientists at work, and look particularly for the methods which they use in attacking their problems . . .

In 1946, James Bryan Conant, educator, scientist, and president of Harvard University, delivered his famous Terry Lectures at Yale and stated that students must understand the tactics and strategies of science, an obvious reference to NOS. He later expressed the view that "some understanding of science by those in positions of authority and responsibility as well as by those who shape opinion is therefore of importance for the national welfare" (1947, p. 4). Conant (1951) later expanded on these ideas by suggesting that "every American citizen … would be well advised to try to understand both science and the scientist as best he can" (p. 3). These are among the earliest and most clearly stated rationales for the inclusion of nature of science as an essential part of science literacy in the United States. Even if the term *nature of science* was not widely used, it is clear that is what these early advocates mind.

The 1957 Soviet launch of Sputnik and the perceived threat to US superiority in science and technology gave rise to what has been called the *Golden Age of Science Education*. During the period following Sputnik extending through the 1960s, various US government agencies funded a large number of projects targeting the improvement of science and mathematics education with study groups and a staggering number of curriculum development projects. These were all designed to bolster the nature and effectiveness of science and mathematics teaching in the nation (DeBoer 1991).

By 1960, the National Society for the Study of Education argued even more clearly for the inclusion of NOS in school science:

> There are two major aims of science-teaching; one is knowledge, and the other is enterprise. From science courses, pupils should acquire a useful command of science concepts and principles. Science is more than a collection of isolated and assorted facts . . . A student should learn something about the character of scientific knowledge, how it has been developed, and how it is used. (in Hurd 1960, p. 34)

An additional justification for the inclusion of the nature of science in science class comes from science educator Joseph Schwab (1964), who correctly observed that science is taught as an "unmitigated rhetoric of conclusions in which the current and temporal constructions of scientific knowledge are conveyed as empirical, literal, and irrevocable truths" (p. 24). Many of the science curriculum projects of the 1960s – sometimes called alphabet soup projects because of their letter-rich acronyms (such as S-APA, ESS, CHEM Study) – were designed to shift science instruction away from a focus on "what do scientists know" (i.e., content) to an examination "how do scientists know" (i.e., process). Interestingly, several of the science curriculum projects funded by the government as a response to the perceived Soviet threat were expressly designed with NOS elements so that students would have the opportunity to understand how to "do" science in the real world. Of course, this is hardly a surprise since the expressed purpose of these new curricula was to encourage more students to become scientists and engineers.

As the 1960s became the 1970s, several authors reminded science educators of the importance of the nature of science by using that term expressly. Robinson (1968) in *The Nature of Science and Science Teaching* discussed the nature of physical reality including probability, certainty, and causality and concluded with by considering the interplay between science instruction and the nature of science. In *Concepts of Science Education: A Philosophical Analysis*, Martin (1972) reiterated some of these arguments in support of including NOS in science instruction by advocating the use of inquiry learning along with discussion of the nature of explanation and the character of observation in the science classroom.

NOS studies gained traction in the final decades of the twentieth century. There were contributions to NOS studies from increasing numbers of scholars, focused publications in the field and increased advocacy and understanding for the place of the history and philosophy of science in the science classroom. At this same time Duschl (1985) reminded the science education community that the way science was increasingly represented in classrooms was often at odds with a modern view of how science functions.

Next, various organizations in the United States such as the National Research Council (NRC) and the American Association for the Advancement of Science (AAAS) expressed interest in the nature of science. AAAS released an important report defining what literate individuals should know about science, called *The Liberal Art of Science: Agenda for Action* (AAAS 1990). It featured an entire chapter with recommendations for what sort of NOS topics ought to be included in school science. These included science values and ways of knowing, methods of collecting, analyzing and classifying data, the nature of explanations in science, and the limits on scientific understanding.

Without NOS, students will very likely continue to see science only in its "final form," a label coined by Duschl (1990) describing the situation in which students learn only the conclusions of science with little opportunity to experience how these scientific discoveries were made. "Final form science" provides such a shallow view of the scientific enterprise that students are unable to use the methods of science for themselves or to gauge the scientific worth of ideas proposed by others.

61.4 Why Nature of Science Matters: The United States Context

At this point it is important to recognize a special challenge with respect to NOS in US classrooms. Certainly, NOS can help students understand and appreciate the inner workings and limitations of science as a way of knowing. With that goal in mind, it would be hard to imagine than anyone would argue with its inclusion in science class, particularly if NOS knowledge assists science learners become better decision makers on scientific matters.

However, this is precisely why NOS is needed and why some might rather omit it. If students can judge the worth of scientific evidence and conclusions on their own, they will be far less likely simply to accept what others tell them. This has become an important issue with respect to topics perceived as controversial by some in the United States. such as evolution and, more recently, climate change. If students understand how science functions, they would quickly realize that issues like these are not just matters of opinion. In fact, they are matters of science not politics, not religious doctrine, and most certainly not just opinion. If the scientific evidence demands reaching a particular conclusion, then that is the most reasonable conclusion to accept even if it is unpalatable for some external reason like religion, politics, or preference.

As a case in point, consider the case of biological evolution and those who reject it because of their motivation by a particular worldview (Moore et al. 2009). Evolution denial has been active for more than a century; since education was governed locally for much of the history of the United States, evolution was simply not taught as too heretical. Following the famous 1925 Scopes trial in the southern state of Tennessee, there was a national debate about the teaching of evolution that generally left evolution out of most science classrooms. Space does not permit a full account of the battles in both courthouses and the court of public opinion, but even the last major skirmish which occurred probably will not end the attacks. In 2005, the Dover Area School District in Pennsylvania lost an expensive and foolish fight to defend their policy requiring the teaching of intelligent design along with evolution as an "alternative" in biology class (Humes 2007).

It is not clear if those who deny evolution and climate change are sophisticated enough to understand that when students have the tools to think for themselves they will either accept or reject scientific ideas based on the merits of the ideas themselves rather than with reference to some preformed ideology. Perhaps the long tradition of democracy in the United States has caused some to think that we can and should vote on everything including the validity of scientific ideas. If students and their parents fail to understand the guiding principles of science, they may think that all knowledge from any source is essentially a matter of opinion, and therefore, equally valid. This relativistic approach has given rise to the "science wars," which are a subset of the greater "culture wars" that have raged in some decades. Such "wars" result either when one group feels excluded by the knowledge generation methods and traditions of another or when a group assumes the position that no source of knowledge – including science – produces more secure results than any other (Parsons 2003; Brown 2001). Students are the causalities of these "wars" when important elements of the curriculum are eliminated or minimized or even mocked. This happened with evolution and is occurring with climate change.

The battle against evolution and the growing rejection of global warming have shared roots in a lack of understanding of how science functions. A firm appreciation of the limits of science should enable those who question evolution to recognize that its acceptance does nothing to negate most religious beliefs. Those who reject climate change on ideological grounds will be much less likely do to so if they understand that science forms conclusions not on the opinions of a few but on the preponderance of the evidence as analyzed and interpreted by the community of scientists worldwide. Only through knowledge of the nature of science can students understand how science produces and validates knowledge. Given the continuing tensions about the process and products of science in the United States, knowledge of NOS is arguably more important here than in almost any other nation. With that thought in mind, we can turn our attention to what aspects of the nature of science should inform science teaching and learning.

61.5 Nature of Science in US Science Education Standards Documents

Many involved with science education in the United States would likely agree with a decision to call the recent decades as the *Age of Standards* in science education. In a relatively short time two documents were designed to guide the teaching and learning of science at a national level. Of course, some states already had their own documents, but the advent of the national standards movement gave rise to the development of the first major sets of science standards. Interestingly, two documents from two different groups – with some overlap in committee membership – appeared almost simultaneously.

The first of these came from the American Association for the Advancement of Science (AAAS)-sponsored *Project 2061* (1989) (designed to reform science teaching by the time Halley's Comet returns in 2061) and the related *Benchmarks for Science Literacy* (AAAS 1993). Just 3 years later, the National Research Council released its own proposal for the content of school science boldly titled the *National Science Education Standards* or *NSES* (NRC 1996). In spite of a high degree of similarity between them, the *Standards* made the recommendation that science should be taught through inquiry, while *Benchmarks* is generally silent on how science should be taught. Of course, given the issue of educational governance in the United States, neither set of guidelines could be imposed and, in fact, no state fully adopted all of the recommendations.

A detailed comparison of *NSES* and *Benchmarks* (McComas and Olson 1998) revealed that both documents provided many targeted recommendations regarding the nature of science for K–12 science instruction. Both documents generally describe how science functions and builds new knowledge by mentioning the common characteristics of science including the use of careful measurement, observation, experiment, peer review, and potential for replication. Science is labeled as tentative, calling theories and laws as related but distinct aspects of science; science is portrayed as a collaborative and social human endeavor affected by the social and historical milieu within a domain of creativity. Neither document provided as complete a description of science for science teaching as recommended by Lederman (2002, 2007), McComas (1998, 2008), and Osborne and colleagues (2003). However, the strong NOS message in these two documents affirmed the nature of science as a necessary part of the science teaching enterprise that could no longer be ignored.

So, the debate about *whether* to teach NOS has ended leaving open only the question about *what* NOS elements should be taught. The response to this challenge may best be achieved by using the consensus approach which considers the common views of various science education experts. Some, such as van Dijk (2011), reject the consensus approach for making this determination partially on the grounds that the final picture that emerges is not a complete view of NOS. Perhaps, but this is no more or less true than the consensus about what to teach that resulted from an examination of traditional science topics such as chemical reactions, photosynthesis, and the rock cycle. Anything we teach students about science and its nature should be accurate with respect to the needs and abilities of the target audience. However, the goal in defining what NOS to teach in schools is predicated on what students need to appreciate the scientific enterprise, what they can understand, and what the curriculum can support, not in providing an obsessively complete view of the nature of science as known by historians and philosophers of science.

One particularly fruitful approach about what NOS to teach is found in an analysis of science standards from each of the US states. These documents can be seen as quasi-independent opinions (of course, many of those who crafted these documents reviewed the foundation same literature) on NOS that allow us to reach some common ground on what elements of the nature of science should best inform school science teaching.

61.6 Nature of Science in the US State Science Standards

The US state science teaching standards have traditionally been in flux both due to the ongoing cycle of revision and updating. This change will continue because most of the state science standards will disappear as the new standards are adopted. Therefore, an analysis of the existing standards just before the adoption of the *Next Generation Science Standards* can provide both an interesting historical review and a rich picture of NOS instruction in the United States with great potential for reaching agreement on the nature of science in schools.

McComas and colleagues (2012) reviewed the then-current science content standards of the 50 US states and the District of Columbia (N = 51) to determine what NOS content was included. The investigation was focused on a search for the appearance of any of 12 elements of the nature of science[1] most commonly recommended by experts (Al-Shamrani (2008). These are called key aspects of NOS and detailed as a part of Table 61.1.

---

[1] The 12 key NOS elements were used to guide the search, but researchers were attentive to and noted all instances of NOS-related language found in thousands of lines of text in 51 documents. In these documents, more than 3400 instances of NOS were located and categorized.

Table 61.1 The percentage of US state standards documents in which specific key aspects of the nature of science appears at least once (N = 51)

Key aspects of NOS found in a review of all US state standards documents in the spring of 2012 (N = 51)	Percentage of state standards documents in which specific aspects of NOS appear (%)
Science is based on empirical evidence	96
Cooperation exists in science	90
Scientific conclusions have a degree of tentativeness	90
Distinction between observation and inference	86
Role of experiments in science	86
Distinction between science and technology	84
Science is socially and culturally embedded	76
There is no stepwise scientific method	71
Science has a subjective element	61
Distinction between law and theory	55
Science cannot answer all questions (i.e., there are limits to science)	49
Creativity has a role in science	25

Each appearance of NOS was noted to (a) identify which NOS elements appear, (b) gauge where they appear with respect to educational level (elementary, middle, and secondary), (c) determine how many of the key elements are included (this is called completeness), (d) measure the distribution or comprehensiveness of NOS elements with respect to their inclusion in and across grade levels, and (e) rank the state standards documents based on a combined measure of completeness and comprehensiveness. In brief this analysis provides an in-depth look at NOS in US public schools just before the introduction of new science instructional standards.

61.6.1 Nature of Science in the US State Standards

Table 61.1 reports the specific key NOS elements that appear in the science standards of each state; data provided next will provide much more detail about where the NOS element appears with respect to grade level and with what frequency. These data reveal which key NOS elements (empiricism, tentativeness in science, cooperation and collaboration in science, the distinction between observations and inferences, and the role of experiments) are included within the standards of most states. From this review, creativity, the idea that science cannot answer all questions, and the distinction between law and theory are shown to be included less frequently than other notions in the state science standards.

Table 61.2 The US states listed with the number of key NOS aspects included in their science content standards along with a "letter grade" associated with that number of key aspects of NOS

Score	Number of key aspects of NOS included	State
A+	12	NE, NH, NC, OH
A	11	FL, IN, KY, ME, MI, MN, MO, NV, NJ, NY, OR, TN
B	10	AK, GA, KS, LA, MA, MS, NM, ND, DC
C	9	ID, IL, MD, VA, WA, WV
D	6–8	AL, AZ, AR, CA, CO, HI, MT, OK, PA, SD, UT, VT, WI

61.6.2 Which US State Standards Contain the Most NOS Elements?

The data in Table 61.2 show how likely it is that a state document would include a complete range of all recommended NOS elements. Sixteen states rate highly in terms of completeness; some states (Nebraska, New Hampshire, North Carolina, and Ohio) have all 12 key NOS elements in their science content standards.

61.6.3 The Nature of Science Recommendations for Grade Level in the US State Standards

The empirical aspect of science, the role of cooperation, the distinction between observation and inference, and the distinction between science and technology are the most likely NOS elements to be found across grades K–12. Creativity and the distinction between theory and law are introduced only at the higher grade levels (Table 61.3).

61.6.4 Combining Completeness and Comprehensiveness: How Do the States Rank for NOS Inclusion?

Using a weighted system by which states earn "high marks" for having the most NOS elements included most frequently *across* grade levels, we ranked each state based on how NOS is featured in its science teaching standards. This ranking system is based on determining a top score in which all of the NOS elements would appear in the standards at every grade level. However, achieving this top score is not anticipated or even advocated since some NOS elements might be inappropriate for younger learners. Therefore, the final analysis was a norm-referenced scale that reveals what states thought was possible rather than for the researchers to suggest

Table 61.3 The percentage of state documents in which each key aspect of the nature of science appears generally (N = 51) and appears at a particular grade-level span

Key aspects of NOS found in US state standards	Percentage of documents in which the NOS element appears	Percentage of state documents in which a NOS element (sub-domain) appears at a particular grade level span as a measure of comprehensiveness			
	(%)	Grades K–2 (%)	3–5 (%)	6–8 (%)	9–12 (%)
Science is based on empirical evidence	96	59	88	78	80
Cooperation exists in science	90	63	71	80	84
There is a tentative element in science	90	24	41	73	67
Distinction between observation and inference	86	51	65	55	57
Role of experiments	86	27	69	76	71
Distinction between science and technology	84	59	73	73	67
Science is socially and culturally embedded	76	35	51	55	63
There is no stepwise scientific method	71	22	43	57	57
Science is somewhat subjective	61	14	35	47	43
Distinction between law and theory	55	4	16	33	47
Science cannot answer all questions (i.e., there are limits to science)	49	39	39	35	37
Creativity play a role in science	25	6	10	16	14

what was ideal. Space limitations preclude including the results for each state, but Tables 61.4 and 61.5 provides the norm-referenced ranking of those states that scored highest when considering both completeness and comprehensiveness.

Not unexpectedly, no state suggested that all of the key NOS elements should be included at every age/grade level. If we treat the 50 states as independent experiments in writing NOS-related standards, we can learn much about consensus and innovation. For instance, it is possible to note that some of the NOS elements are more likely to be recommended for younger students, while other NOS content is generally reserved for those in the upper grades. This is an important consideration in the design of science curricular.

Not surprisingly, there is a huge variance in terms of NOS inclusion when comparing the fifty-one US science content standards. The authors of this study found that many states include both a complete picture of recommended NOS content and do so across grade levels. This strategy of returning to content repeatedly at higher

levels of abstraction and/or complexity across grade levels is an excellent application of the spiral curriculum in instructional design. Some of the recommended NOS elements are complex enough that students would learn little from a one-time encounter. NOS is so integral to an understanding of the scientific enterprise that including some elements only at one grade level or only at a particular time in the science curriculum would reduce the likelihood that students would understand the concept and appreciate its significance. So, those states that expect students to engage NOS content early and often are to be congratulated.

However, as with everything else of importance in the educational enterprise, actual NOS instruction in classrooms is in the hands of teachers. No matter how robust the state standards are, such standards are embraced and interpreted by the 7.2 million teachers in 15,000 school districts across the nation (US Census Bureau 2011). What NOS instruction looks like in one classroom may be quite distinct from such instruction in another classroom, even in the same school.

This analysis of the multiplicity of guidelines produced in the last decade demonstrates that NOS is important and that there is a consensus among science educators and policymakers toward what elements of the nature of science are most appropriate to inform school science instruction (see Table 61.1). Furthermore, the analysis has also provided evidence of which particular NOS aspects are most appropriately included at each grade-level span (Table 61.3). Such data are of vital importance in designing future science standards guidelines.

61.7 Nature of Science: An Emerging Consensus View

Figure 61.1 is a graphical organizer of a consensus view of the nature of science designed to inform school science. This plan is based on a review of the prevailing experts, a review of the fifty-one US state documents (McComas et al. 2012) and earlier suggestions from McComas (2008).

Here, the nine recommended elements of the nature of science are arranged in three suites of related items: the tools and products of science, science knowledge and its limits, and the human elements of science. Nine domains or key aspects of NOS (empirical basis, shared methods, subjectivity, creativity, and others) are not suggested as complete descriptions. Also, when elucidated and discussed, it will be obvious that some of these nine are more extensive in scope and content than others. For instance, the NOS element "science has shared methods" relates to a range of issues including the ideas that there is no single step-by-step method and that scientists share techniques such as good record keeping and use of induction, deduction, and inference. On the other side of the figure, we find the distinction between science and technology noted. This is a relatively discrete idea stating that students should understand the distinction between the roles and processes of science and those of technology and engineering. Such distinctions are more important than ever given the inclusion of engineering in the *Next Generation Science Standards*. The point to keep in mind is that the "size" of each other nine recommendations is

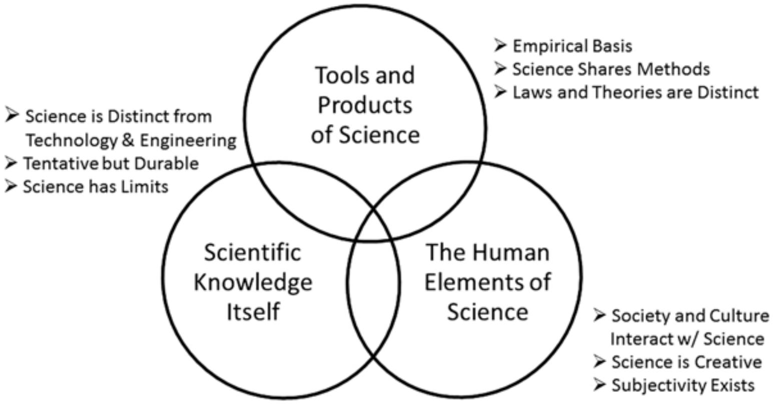

Fig. 61.1 A graphical representation of nine basic NOS elements frequently recommended for use in K-12 science instruction, arranged into suites of related items (Adapted from McComas (2008))

not the same nor is the level of complexity of the underlying idea. Textbook authors, curriculum designers, and, of course, teachers will ultimately be responsible for how these ideas are integrated into classroom instruction.

Figure 61.1 is nothing more than a potentially useful way to illustrate the range and relationship of the NOS elements most commonly recommended to inform and enliven science teaching in schools. There should be no implication that these elements are simply to be memorized on the first day of school and quietly forgotten. Rather, these elements must be explicitly explained, illustrated with examples, mentioned in context with discussion of science content, and assessed to gauge student understanding.

61.8 The Next Steps in US Science Instruction: The Framework for K-12 Science Education and the Next Generation Science Standards

One of the challenges with respect to providing an overview of the nature of science in the US context is that change in the educational landscape is constant. This is particularly true now that many of the US states are poised to adopt shared new science instructional standards, presumably abandoning their specific state learning goals. Colleagues in mathematics and English/language arts education have already faced this situation. Many of the US states have accepted what is called the "Common Core" (*Common Core State Standards for English Language Arts & Literacy in History/Social Studies, Science, and Technical Subjects*), a set of shared instructional standards in these disciplines (Council of Chief State School Officers 2010; Rothman 2011). Also, students are to develop appropriate levels of writing and reading literacy in the content area of science.

The latest revolution in science instruction in the United States began with the release of a new document designed to guide science teaching at the precollege level titled *A Framework for K-12 Science Education: Practices, Crosscutting Concepts, and Core Ideas* (National Research Council 2012). The recommendations in the *Framework* have already been transformed into various draft versions of the *Next Generation Science Standards (NGSS)* which, in turn, have been reviewed by working groups across the nation. As is often the case when it comes to shared initiatives, a few states have decided not to endorse the *Next Generation Science Standards*, so some diversity in the nature of the US science curriculum will continue to exist. However, the vast majority of US states plan to adopt the *NGSS* recommendations thus shifting the balance of power in education, in a curricular sense, quite dramatically.

61.8.1 A Framework for K-12 Science Education

Since the *Framework* (NRC 2012) represents a major new source of thinking about science teaching in the United States, it will be examined in detail with respect to its

Table 61.6 The three dimensions of the Framework for K-12 Science education: practices, crosscutting concepts, and core ideas (NRC 2012, p. 3). One example from each disciplinary core idea is provided as an illustration, but there are many more

1. Scientific and engineering practices
    1. Asking questions (for science) and defining problems (for engineering)
    2. Developing and using models
    3. Planning and carrying out investigations
    4. Analyzing and interpreting data
    5. Using mathematics and computational thinking
    6. Constructing explanations (for science) and designing solutions (for engineering)
    7. Engaging in argument from evidence
    8. Obtaining, evaluating, and communicating information
2. Crosscutting concepts
    1. Patterns
    2. Cause and effect: mechanism and explanation
    3. Scale, proportion, and quantity
    4. Systems and system models
    5. Energy and matter: flows, cycles, and conservation
    6. Structure and function
    7. Stability and change
3. Disciplinary core ideas
    - Physical science (such as matter and its interactions)
    - Life sciences (such as from molecules to organisms; structures and processes)
    - Earth and space science (such as Earth's place in the universe)
    - Engineering, technology, and applications of science (such as engineering design)

inclusion of aspects of the nature of science. The Framework is a narrative result of discussions from expert groups empaneled to ensure accurate science content and provide a set of broad expectations for science and engineering education in the K-12 learning environment. The *Framework* provides recommendations in three domains including science and engineering practices, crosscutting concepts, and core ideas in life, physical, and Earth/space sciences. Although engineering and technology were mentioned in previous standards documents, engineering has risen to a status almost equal to that of science itself. In fact, the *Framework* is endorsed by the presidents of the National Academy of Sciences *and* the National Academy of Engineering.

Since these three dimensions are inherent in the design of the *Framework* and to the new standards, it is useful to include them here (Table 61.6). Some of these dimensions do relate to elements of the nature of science, but it is important to note that NOS itself does not appear explicitly even though "how science works" could certainly be considered a crosscutting concept.

A number of techniques were used to analyze the *Framework* for its inclusion of NOS elements including the application of the new computer search tool (Jiang 2012) specifically developed to look for inclusions of specific content in large digital files. In addition, the search examined the index in the *Framework and* performed keyword searches within the *Framework*, accompanied by a reading of the *Framework* to establish context.

The computer-assisted search found that most of the major recommended ideas in the nature of science appear in the *Framework.* Of course this is encouraging. However, a closer examination of the document reveals that although NOS is stated and implied at various places in the text, but not explicitly recommended anywhere. The key NOS concepts are scattered throughout the document rather than being located in one section, and only a few appear in the index. Even the term "nature of science" only appears in the index (science, nature of) in a discussion of recommendations for improvement to the *Framework*. This is curious considering the following strong statement:

> any [science] education that focuses predominately on the detailed products on the detailed products of scientific labor—the facts of science—without developing an understanding of how those facts were established or that ignores the many important applications of science in the world misrepresents science . . (NRC 2012, p. 43)

As a way of considering what the *Framework* contains with respect to the nature of science, these next few sections will examine how the NOS concepts of creativity, scientific method, inference, law/theory, tentativeness, limits of science, subjectivity, and the social elements of science are treated in the *Framework.* It is particularly noteworthy to see how widely scattered the references are and how diligently one would have to search the entire *Framework* and infer in order to derive a useful recommendation for nature of science.

61.8.2 Creativity in the Framework

Most experts agree that creativity is an important part of science, and the *Framework* mentions this fact in the following places: "They [students] should come to appreciate that science and the current scientific understanding of the world are the result of many hundreds of years of creative human endeavor" (NRC 2012, p. 9). "Not only is such an approach alienating to young people, but it can also leave them with just fragments of knowledge and little sense of the creative achievements of science, its inherent logic and consistency, and its universality" (NRC 2012, p. 10). "…the insights thus gained help them [students] recognize that the work of scientists and engineers is a creative endeavor—one that has deeply affected the world they live in" (NRC 2012, pp. 42–43). "…construction of explanations or designs using reasoning, creative thinking, and models" (NRC 2012, p. 44), and "the creative process of developing a new design to solve a problem is a central element of engineering" (NRC 2012, p. 206).

61.8.3 Scientific Method in the Framework

The notion that there is no single stepwise scientific method appears in the *Framework* in a variety of places, but there is no single description of what this means, nor is the term found in the index. Consider the following statements: "Second, a focus on practices (in the plural) avoids the mistaken impression that there is one distinctive approach common to all science – a single "scientific method" – or that uncertainty is a universal attribute of science" (NRC 2012, p. 44). "For example, the notion that there is a single scientific method of observation, hypothesis, deduction, and conclusion—a myth perpetuated to this day by many textbooks—is fundamentally wrong" (NRC 2012, p. 78). "Thus the picture of scientific reasoning is richer, more complex, and more diverse than the image of a linear and unitary scientific method would suggest" (NRC 2012, p. 78) and "…and not as rote procedures or a ritualized 'scientific method'" (NRC 2012, p. 254). All of these statements accurately represent the issue related to "scientific method" correctly and appropriately, but the new Framework focuses on science and engineering practices, and the way in which those practices are discussed together in the document could be a source of new misunderstandings about this issue.

61.8.4 Law/Theory in the Framework

For decades, educators have been concerned that students do not understand the relationship between hypothesis, theory, and law. The *Framework* has a multitude of references to the term "hypothesis," several to "theory," but no direct references to the role of law in science. There are the following implied references to "law," but it is not clear why the term itself is missing.

With respect to laws, the *Framework* offers the following: "Repeating patterns in nature, or events that occur together with regularity, are clues that scientists can use to start exploring causal, or cause-and-effect, relationships, which pervade all the disciplines of science and at all scales" (NRC 2012, p. 87). The following statement comes close to providing a definition of "law," but unfortunately it is not referenced in the index:

> One assumption of all science and engineering is that there is a limited and universal set of fundamental physical interactions that underlie all known forces and hence are a root part of any causal chain, whether in natural or designed systems. Such "universality" means that the physical laws underlying all processes are the same everywhere and at all times; they depend on gravity, electromagnetism, or weak and strong nuclear interactions. (NRC 2012, p. 88)

There is a very well-constructed discussion of hypotheses and laws in the *Framework*, a section of which is shown below. Unfortunately, the obvious and necessary link to "law" is absent.

> Theories are not mere guesses, and they are especially valued because they provide explanations for multiple instances. In science, the term "hypothesis" is also used differently than it is in everyday language. A scientific hypothesis is neither a scientific theory nor a guess; it is a plausible explanation for an observed phenomenon that can predict what will happen in a given situation. (NRC 2012, p. 67)

61.8.5 Tentativeness in the Framework

Finally, we consider the idea of tentativeness in the *Framework*. In addition, we find a few statements about this issue such as “any new idea [in science] is tentative …” (p. 79) and “any new idea is initially tentative, but over time, as it survives repeated testing, it can acquire the status of a fact—a piece of knowledge that is unquestioned and uncontested, such as the existence of atoms” (p. 94). Unfortunately, there are problems with both of these statements. In the first case, there is no corresponding statement about how long-lasting (or durable) science knowledge is in practice even if it is tentative. In the second case, the statement is incorrect because it implies that once a “fact” is established, its tentative character is somehow eliminated. Philosophers of science would remind us that all knowledge in science is tentative.

61.8.6 Limits of Science and Subjectivity in the Framework

These important issues are neglected in the *Framework*. There are many mentions of the targets of science and engineering but there is no explicit statement about what science and engineering cannot do. Unless one has a strong background in the philosophy of science, it would not be intuitively obvious that science does not address all problems in all domains. This is a particularly troublesome issue since many students fail to understand that many of their religious notions are not in the domain of science and therefore are not subject to attack by science. In the case of evolution, for instance, students would be well served by knowing that the scientific explanation of biological change through time does not demand that they give up a belief in some metaphysical component to such change.

There are vague implications in the *Framework* that science has subjective elements, but the word appears nowhere in the document. This is unfortunate, because an examination of the history of science provides many examples of how scientists have personally pushed and rejected ideas and interpreted evidence even contrary to the views of others. Sometimes this subjective element is exactly what was necessary for an idea finally to be accepted by the scientific community (i.e., Milliken’s discovery of the charge on the electron). Giving students opportunities to recognized that science has a subjective element is valuable in portraying science accurately and situating science as a human pursuit.

61.8.7 Science as a Social Activity in the Framework

There are a number of references in the *Framework* to the social aspect of science. Consider the following as a good description of this aspect:

> . . . science is fundamentally a social enterprise, and scientific knowledge advances through collaboration and in the context of a social system with well-developed norms. Individual scientists may do much of their work independently or they may collaborate closely with colleagues. Thus, new ideas can be the product of one mind or many working together. (NRC 2012, p. 26)

The only objection to this phrase relates to its placement. As is the case with many of the NOS elements in the Framework, this one is not included along with other nature of science ideas so that readers could see this as part of a broader description of NOS in science education.

61.8.7.1 The Framework and NOS: Conclusions and Concerns

The *Framework* does contain some meaningful suggestions for the nature of science and even includes a section called "understanding how scientists work" with the following powerful statement reproduced here in full:

> The idea of science as a set of practices has emerged from the work of historians, philosophers, psychologists, and sociologists over the past 60 years. This work illuminates how science is actually done, both in the short term (e.g., studies of activity in a particular laboratory or program) and historically (studies of laboratory notebooks, published texts, eyewitness accounts). Seeing science as a set of practices shows that theory development, reasoning, and testing are components of a larger ensemble of activities that includes networks of participants and institutions, specialized ways of talking and writing, the development of models to represent systems or phenomena, the making of predictive inferences, construction of appropriate instrumentation, and testing of hypotheses by experiment or observation.
>
> Our view is that this perspective is an improvement over previous approaches in several ways. First, it minimizes the tendency to reduce scientific practice to a single set of procedures, such as identifying and controlling variables, classifying entities, and identifying sources of error. This tendency overemphasizes experimental investigation at the expense of other practices, such as modeling, critique, and communication. In addition, when such procedures are taught in isolation from science content, they become the aims of instruction in and of themselves rather than a means of developing a deeper understanding of the concepts and purposes of science. (NRC 2012, p. 43)

Unfortunately, what the *Framework* fails to do is to clearly and explicitly feature exactly what NOS elements are recommended and provide some definitions and descriptions in one place to serve as a useful guide for those hoping to use the document to frame instruction in this important area. The NOS suggestions are implied, too widely scattered and much too implicit to be of use to educators not already familiar with the nature of science. To profit from the *Framework*, educators would have to work very hard and infer much to derive a useful list of NOS goals, a task that would be difficult without considerable expertise in this area. It is ironic that the document reports that "Many of those who provided comments thought that the "nature of science" needed to be made an explicit topic or idea. They noted that it would not emerge simply through engaging with practices" (NRC 2012, p. 334). It is curious that the authors had to be informed of this clear fact.

61.8.7.2 The Next Generation Science Standards and the Nature of Science

Following the release of the *Framework*, committees began the development of the *Next Generation Science Standards (NGSS)* with a March of 2013 target date for

Table 61.7 An example of the first of the content standards from the next generation science standards (NRC 2013) showing the link to the nature of science associated with that standard

Section title: K. forces and interactions: pushes and pulls	
Specific goals:	K-PS2-1. Plan and conduct an investigation to compare the effects of different strengths or different directions of pushes and pulls on the motion of an object K-PS2-2. Analyze data to determine if a design solution works as intended to change the speed and direction of an object with a push or pull
Science and engineering practices:	Planning and carrying out investigations Analyzing and interpreting data
Disciplinary core ideas:	PS2.A: Forces and motion PS2.B: Types of interactions PS3.C: Relationship between energy and forces ETS1.A: Defining and engineering problem
Crosscutting idea: Patterns and cause and effect	
Nature of science: Scientific investigations use a variety of methods	

completion. What makes this document different from others is that almost all of the states agreed to use this single set of guidelines to guide science teaching. Another major change is that the NGSS would be based on the science and engineering practices, core ideas, and crosscutting concepts (see Table 61.6) in addition to a blending of science with engineering. The goal of these new standards is that all high school graduates would have enough knowledge of science and engineering to participate in debates about science issues, make informed choices as consumers, and be prepared to enter science-related careers.

Various groups and individuals reviewed the *Framework* and agreed that it failed to adequately illustrate and define the various elements of the nature of science that should inform science teaching. What resulted from this review is a much more robust and complete vision for NOS in the NGSS with eight specific NOS domains discussed in an appendix and included throughout the document. Each domain of grade-level content is linked to the other design elements, but now the nature of science is explicitly included. Consider the following example from the NGSS illustrated in Table 61.7.

Unlike in the *Framework* where the nature of science elements is highly scattered, those in the *Next Generation Science Standards* (NGSS) are found together in a single appendix. There are eight NOS categories each with specific learning goals divided into recommendations for K–2, 3–5, middle school, and high school learners. Table 61.8 includes all of these NOS recommendations along with a description of that learning goal. The authors also indicate that some of the NOS goals are most closely associated with science and engineering practices and some with the crosscutting concepts. While it is not clear why this is important, perhaps the authors hope that teachers will be able to teach aspects of NOS while teaching some of the other recommended content.

Table 61.8 Categories of nature of science found in Appendix H of the next generation science standards (NRC 2013). Additional detail provided has been extracted from the specific details associated with the learning goals stated for each of the grade level (K–2, 3–5, middle, and high school). Those goals thought to be most associated with science and engineering practices are labeled Pr, and those most closely linked to crosscutting concepts are labeled Cr

Scientific investigations use a variety of methods (Pr); this implies that there is no step-by-step method, but this is not stated, that students are to distinguish between science and nonscience, and that scientists share values such as objectivity and open-mindedness

Scientific knowledge is based on empirical evidence (Pr); the grade-level expectations for this NOS element are much the same and self-evident that science requires evidence

Scientific knowledge is open to revision in light of new evidence (Pr); this implies that science is tentative but this is not stated explicitly

Science models, laws, mechanisms, and theories explain natural phenomena (Pr); theory and law are said to be individual and unique elements of science. Useful and accurate definitions are provided

Science is a way of knowing (Cr); additional information relates to the unique elements of science (such as empiricism and skepticism) and the view that scientific modes of inquiry can be used by sciences and nonscientists and that contributions to science come from various types of people

Scientific knowledge assumes an order and consistency in natural systems (Cr); this notion relates to an expectation that nature is orderly and develops this idea across the grade levels

Science is a human endeavor (Cr); all types of people have contributed to science and continue to make contributions and that science influences and is influenced by society. Other issues mentioned include creativity, some discussion of science, and its link to technology

Science addresses questions about the natural and material world (Cr); the NOS category includes discussion of the target of science, the notion that science cannot answer all questions, and the role of science in decision-making

The way in which these eight NOS ideas are linked to the specific learning objectives seems more of an afterthought than something strategic, but this reviewer is pleased to see NOS represented so prominently. In the example provided earlier (Table 61.7), please note that the NGSS considers that when young students learn about “forces and interactions,” this would be a good time to demonstrate that “scientific investigations use a variety of methods.”

61.8.8 Next Generation Science Standards: Conclusions and Critique

There is no doubt that the authors of the *NGSS* responded appropriately to the comments made by those who reviewed the *Framework*. The nature of science goals is more explicitly stated and organized. However, there are still some issues regarding NOS of some concern. These include the perception that some of the ideal NOS elements are missing, the nature of the narrative justifying NOS in the NGSS Appendix, the placement of NOS in the *NGSS*, and the potential challenges associated with potential conflating of science and engineering in the minds of students.

With respect to what is missing, the most glaring omission is an explicit statement indicating that science advances both through organized means and through somewhat subjective ones. It would be reasonable to include this in the category of "science is a human endeavor." Creativity should be mentioned more consistently. Currently, the ideas of "creativity and imagination" are noted only as grades 3–5 and high school goals within the human dimension category. Of course, it is reassuring to see this characteristic of science listed at all, but there is little reason for its lack of prominence. It would be useful to discuss the relationship of tentativeness and durability across grade levels rather than saving such discussion only for high school students. The *NGSS* standards are silent on the distinction between inference and observation, an issue that could be easily corrected in either of the first two categories, "variety of methods" or "empiricism."

Since the *Standards* include engineering goals along with those for science, one would have expected to see a NOS goal statement distinguishing science from technology and engineering. Formally, suggestions to include this NOS element had not been embraced by the science education community, but must now rise in importance because of the curious design of the *NGSS*. The *NGSS* and its blend of science and engineering present the danger that students may consider science and engineering as similar, therefore confuse the two. These two disciplines are not the same; they have distinct goals and distinct methods, and although there are advantages in blending scientific ideas with their application through engineering, educators must work very hard to distinguish one from the other.

In conclusion, two other concerns about NOS in the NGSS come to mind. First, the rationales, research, and proposed instructional mechanism for NOS provided in Appendix H are remarkably shallow. The brief section discussing the development of NOS is incomplete; there has been significant work done in recent decades to justify the inclusion of NOS but that has not been included in any strategy or complete fashion. For instance, the use of history as a means by which NOS may be included in the classroom is fine, but there are many other ways to integrate nature of science and science teaching, yet the *NGSS* offer no other suggestions. The two charts listing the key NOS elements are very well designed, but they offer a learning progression for teaching aspects of NOS across the grade levels that does not seem to have been based on a review of the research. Finally, the positioning of the NOS links at the bottom of each page of science content goals makes it appear that NOS was an afterthought. All those who recognize that NOS is fundamental to students' understanding of the scientific process will have to redouble efforts to ensure that reality prevails as the national embraces these new science standards.

61.9 Standards and the Nature of Science: Challenges and Conclusions

In the United States there is no mechanism yet in place to guarantee that any particular science content, including NOS, is taught in each classroom in an appropriate and complete manner. Having well-reasoned standards is a very good step, but issues of assessment, teacher preparation, and targeted curriculum approaches to teaching the nature of science are also important.

61.9.1 Assessment and the Nature of Science

Through national legislation known as *No Child Left Behind*, the US federal government has mandated that some science content acquisition be measured by end-of-course (EOC) evaluations. However, presently there is no single measure applied nationally and few of the state-developed instruments measure much that could be considered related to the nature of science. This situation may change with the widespread adoption of the *Next Generation Science Standards*. When the majority of US states are using the same science teaching standards, it will become increasingly cost-effective to produce assessment tools for use widely. Such assessments become a powerful "policy lever" to encourage teachers to include any specific content in instruction. Of course, this content must include the nature of science.

Although there is now an increasing consensus on what aspects of NOS should be communicated in school settings, the problem of assessment has not yet been fully addressed. We simply do not have valid, reliable, and complete measures of NOS that can be administered to large groups of students and scored quickly in a cost-effective manner. We are also still grappling with important considerations such as how contextualized any measures of NOS must be to be valid. In other words, must NOS items in a biology end-of-course test be different markedly from those used for physics students? Another challenge has been to develop assessment tools that provide some detail about what students know of the various NOS subdomains such as those indicated in Table 61.7.

Therefore, some effort must be expended to develop valid and reliable NOS assessment instruments with useful and robust subscales to help determine what students understand about the nature of science and make sure that such items are included on all end-of-course examinations. Completing both of these tasks will encourage educators to include NOS in instruction, while the results of these assessments will permit educators and researchers to visualize what specific elements of NOS are being communicated effectively in schools.

61.10 Science Teacher Preparation and the Nature of Science

Another force that has potential to unite the states with respect to science teaching relates to preparation of science teachers. Many states have adopted the teacher education standards associated with one of the national accreditation organizations (such as the National Council for the Accreditation of Teacher Education or NCATE), a nongovernmental group. Therefore, by default and design, the teacher education programs governed by NCATE have common elements because of the guidelines imposed on them by these accreditation boards.

This issue becomes somewhat complicated because NCATE refers instructions that prepare teachers to the science content standards developed by the National Science Teachers Association (NSTA). The NCATE database shows that there is at least one academic institution within each state in the United States accredited by NCATE. So, for those science teacher education programs that use NCATE/NSTA, the 2003 standards are quite detailed with respect to the nature of science.

Strand 1 of the NSTA Standards (NSTA 2003) (science content) requires that teachers have implicit knowledge of nature of science under the subheading "concepts and principles" and perhaps "unifying concepts." Explicit knowledge is required under Standard 2 (nature of science), which includes both history of science and nature of science. The rationales provided for NOS inclusion are strong and include many of the NOS elements mentioned frequently by science educators including issues such as tentativeness, empiricism, subjectivity, creativity, the use of inference, the lack of a step-by-step scientific method, and the fact that science is embedded in culture. As well, we find recommendations for teaching NOS in an explicit fashion and the use of history to augment NOS lessons.

Beyond this general reference to NOS and NCATE/NSTA, the nature of science is specifically referenced in the competencies only for the states of Texas, Oklahoma, Florida, Missouri, and Massachusetts. As an example, the *Preparation Manual for the Texas Examinations of Educator Standards in* Domain I for Life Science states:

> The science teacher understands the process of scientific inquiry and its role in science instruction. The science teacher understands the history and nature of science. The science teacher understands how science affects the daily lives of students and how science interacts with and influences personal and societal decisions. The science teacher knows unifying concepts and processes that are common to all sciences. (Texas Examination of Educator Standards 2006, p. 6)

Competency 2 further describes what the beginning teacher should know about nature of science, the process of scientific inquiry, and the unifying concepts that are common to all sciences.

The required competencies in the biological sciences for Oklahoma list two areas with explicit reference to nature of science. Competency 2 requires that students "understand the nature of science including the historical and contemporary contexts of biological study" (p. 2–2). Competency 3 is to "understand the process of scientific inquiry and the role of observation, experimentation, and communication in explaining natural phenomena" (Oklahoma Subject Area Tests – Study Guide, p. 2–3). Florida (Florida Department of Education 2011) provides the most comprehensive inclusion of nature of science within the teacher licensure requirements in listing nature of science within all science disciplines including biology, physics, chemistry, and Earth-space science.

The Missouri Department of Elementary and Secondary Education Certification Requirements for Secondary Education (2009) require two semester hours of study in the history/philosophy of science and technology for all secondary science certifications. Under the regulations for educator licensure and preparation approval (603 CMR 7.00), Massachusetts (2012) lists subject matter knowledge requirements for teacher licensure that include methods of research in the sciences, history and philosophy of science, and principles and procedures of scientific inquiry (which many now include as part of the nature of science).

The licensure requirements for the majority of other states demand that a prospective teacher have a degree in the content area plus passing the Praxis II test.

Based on the *Biology: Content Knowledge* informational guide available from the developer of the test, the Educational Testing Service (ETS), we find approximately 12–22 multiple-choice questions out of the total 150 questions that relate specifically to NOS knowledge. These are all listed under the heading *Basic Principles of Science.* The nature of science questions relate to processes involved in scientific inquiry such as making observations, formulating and testing hypotheses, identifying experimental variables and controls, drawing scientific conclusions, and using scientific sources and communicating findings appropriately. Questions also relate to distinguishing differences among facts, hypotheses, theories, and laws; the testable nature of hypotheses; formulation of theories based on accumulated data; and the durability of laws. Finally, questions are also included that deal with the idea that scientific ideas change over time. These explicit questions about the nature of science comprise approximately 8–15 % of the Praxis II content knowledge test for biology, for example.

This is encouraging; it is clear that those thinking about science teacher preparation have come to value the nature of science, and there is some expectation that teachers who complete accredited programs would have some basic knowledge of NOS. Of course, there is no way of knowing if these teachers value and include NOS content in their classes nor do we know if these teachers preparation programs include a discussion of curriculum strategies for teaching the nature of science.

61.11 US Textbooks and Curriculum Innovations to Support NOS Instruction

One way that nature of science could become a more visible and integral part of the science curriculum is through its focused inclusion in science textbooks. If texts were to feature strong NOS elements – particularly if NOS is included throughout the book – there is a good chance that teachers and students would give more attention to this important topic.

However, in the highly competitive world of textbook publishing in the United States and the long-standing principle of permitting most schools to choose which science books to purchase, all textbooks authors will have to focus more clearly on the nature of science. This is more likely now given the widespread adoption of the *Next Generation Science Standards* and their reasonable focus on the nature of science. The challenge is not just to ensure that science textbooks include an accurate treatment of the nature of science linked to the traditional science content, but such books must integrate NOS throughout the text in a robust fashion.

The hope is that new texts will avoid the current tradition in which whatever NOS content included is relegated to the opening chapter with almost no additional NOS content woven into the subsequent chapters that feature standard science content. This is unfortunate, because many teachers likely move quickly through or skip that first chapter and therefore miss opportunities to share NOS content with students. An additional challenge is for teachers to have access to curriculum models to support engaging instruction in the nature of science. As we will see, although some models have been developed, almost none have entered common use.

61.11.1 Curriculum Innovations and the Nature of Science

Even though explicit and wide-ranging NOS lessons are all absent from current US textbooks, there have been a few important curriculum projects designed to support NOS instruction. The first example of a project targeting NOS instruction draws on the history of science and a set of ancillary study units that apply the case approach. The next two come as a direct result of the US government funding designed to reinvigorate and redirect science and mathematics education through new curriculum models following the launch of Sputnik in the late 1950s. These examples include a classic "alphabet soup" curriculum project called *Science – A Process Approach*; a textbook, *Project Physics*, with multiple NOS inclusions; and several media-centered approaches. There are other NOS examples found in a review of the history of curriculum development in the United States, but sadly none made long-lasting impacts on the inclusion of NOS in the typical science classroom. However, all of these stand as important testaments to the potential a NOS-focused science curriculum and should be studied carefully by those wishing to reestablish the nature of science in science instruction.

61.11.2 The Case History Approach: Conant and Klopfer

A focus on NOS in these curriculum innovations was offered in the previous decade by J.B. Conant an influential scientist, government official, and president of Harvard who stated "…it is my contention that science can best be understood by laymen through close study of a few relatively simple case histories…" (Conant 1947, p. 1). With this simple statement, the use of history as a dominant approach to NOS instruction was born.

Conant's suggestion for the use of history of science in science instruction resulted in what is the most noteworthy example of the case approach, *The Harvard Case Studies in Experimental Science,* which grew out of a general education course beginning at Harvard in 1948 and ultimately published in two volumes (Conant and Nash 1957). The seven cases focused on issues such as Robert Boyle and pneumatics, phlogiston theory, temperature and heat, atomic molecular theory, plants, spontaneous generation, and the historical development of the concept of electric charge.

Later, Conant's student and later fellow Harvard professor, Leo Klopfer along with Cooley (1963), adapted the case study approach for use in high schools with *the History of Science Cases (HOSC)*. Each of these units included the exploration of a major scientific idea through the examination of excerpts of historical documents and experimentation carried out either by students themselves or as a demonstration by the teacher (Lind 1979). The nine titles proposed or developed for HOSC were each represented by individual guides for teachers and their students. The units included exploration of cells, the chemistry of carbon dioxide, Fraunhofer lines, electricity and life (with the intriguing title *Frogs and Batteries*), the discovery of halogen elements, air pressure, plant reproduction, atomic theory, and the speed of light.

The overarching goals for HOSC were to show students the methods used by scientists; the means by which science advances and the conditions under which it flourishes; the personalities and human qualities of science; the interplay of social, economic, technological, and psychological factors with the progress of science and the importance to science of accurate and accessible records; constantly improved instruments; and free communication between scientists (Klopfer 1964).

61.11.3 S-APA: Science: A Process Approach

This project was developed starting in 1962 by the AAAS Commission on Science Education with funding from the National Science Foundation based on the learning theories of psychologist Robert Gagne. The basic premise of S-APA was that the "first and central purpose of science education is to awaken in the child, whether or not he will become a professional scientists, a sense of the joy, the excitement, and the intellectual power of science" (AAAS 1967, p. 1). The basic notion was to give students a variety of hands-on experiences based on a hierarchy of skills (called process skills) that scientists were seen to use regularly.

The processes that the students experienced included observation, classifying, using numbers, measuring, using space/time relationships, communicating, predicting, and inferring (called the basic processes for the primary grades). These were joined by integrated process for upper grade students and included defining operationally, forming a hypothesis, interpreting data, controlling variables, and experimenting.

It should be clear that a number of important NOS ideas were contained among the processes even though S-APA was not designed expressly to communicate such goals. Unfortunately, S-APA like so many of these curriculum projects was never widely used. It quickly faded from the scene because of its uniqueness, its lack of focus on science content, and its decontextualized nature (Finley 1983). However, many of the individual lessons provide wonderful lesson opportunities for teachers today who want a hands-on approach to the nature of science.

61.11.4 Project Physics: NOS in a Textbook Setting

One of the most important text-based projects to feature NOS was *Project Physics* (also called *Harvard Project Physics*) authored by Gerald Holton, F. James

Rutherford, and Fletcher Watson. This book was remarkable in its desire to merge the traditional content of physics with the human side of science. In the introduction to the 1981 edition, the authors write that one of their goals was for students to see "physics as the wonderfully many-sided human activity that it really is. This meant presenting the subject in historical and culture perspective…" (p. iii). The book meets this challenge on almost every page by prominently discussing the people who contributed to modern physics.

As an example, consider the prologue which begins "It is January 1934 in the city of Paris. A husband and wife are at work in a university laboratory. They are exposing a piece of ordinary aluminum to a stream of tiny changed bits of matter called alpha particles" (Holton et al. 1981, p. 1). It is impossible to find another science text that so deliberately shares the human side of science with students in such an explicit fashion. It the pages of *Project Physics*, readers could encounter all of the greats and near-greats of physics while learning the traditional science content.

With both Conant's case study approach and the humanistic physics of Holton, Rutherford, and Watson, we see innovative approaches to the inclusion of nature of science content in science curriculum. Sadly, there have been very few other such products, and even these were only marginally successful. Project Physics had a much longer life; it was produced in several editions, and by far more teachers and students than the case study materials or *S-APA*, but in the end, neither approach can be found in use today.

61.11.5 Using Media to Teach the Nature of Science

There have been some excellent ancillary materials produced such as the *Mechanical Universe Project* created and hosted by David Goodstein of the California Institute of Technology in 1985 and *Mindworks* in 1994 by Barbara Becker (Becker et al. 1995). Both of these initiatives produced high-quality video reenactments of important scientists and their discoveries. The good news is that *Mechanical Universe* is available on line for streaming by teachers who would like to use the reenactments to enliven their presentations of science content and teach some important NOS lessons at the same time.

In fairness, many former curriculum projects and current texts do include some discussion of NOS, typically in the opening chapter, and often feature the names and dates of the most famous scientists, typically in side bar material. Unfortunately, NOS in this fashion is too easy to ignore by teachers and students. The sad reality is that in spite of a number of notable innovations including those mentioned here, the US science curriculum today does not look much different than it did before the widespread interest in and rationales for the inclusion of the nature of science.

61.12 Conclusion

The United States is a unique environment for education with its decentralized educational bureaucracy, a multitude of special interest groups involved in policymaking, free-market choice of textbooks, and individual state control over the curriculum and end-of-course (or exit) assessments. However, this review provides some reasons to be encouraged. We have seen the development of some interesting curriculum models to support NOS instruction, and there is increasing and widespread interest on the part of the science education community that NOS is an important learning goal. In addition, science educators have provided strong rationales for the inclusion of NOS and have defined a set of NOS sub-domains appropriate for use in school settings. *The Next Generation Science Standards* feature most of the recommended elements of NOS in a prominent fashion using a spiral curriculum approach to ensure that NOS is included each year. Perhaps the states will respond to these new standards by requiring that preservice teachers have significant experience with the nature of science. This suggestion for improvement cannot be overstated. Those who teach science certainly will have learned much science content while earning their degrees, but the same claim may not be made regarding teachers' understanding of how science functions. As a case in point, only science teachers repeat the inaccurate notion that there is a scientific method; scientists know better. However, science teachers learned this faulty idea in the pages of the science textbooks since they learned very little about the structure and processes of science while digesting the diet of "final form" science in their prior school and university experiences. Perhaps if those learning science were permitted to look "behind the curtain" and gain an understanding of the nature of science, those who become teachers could carry those lessons into their classrooms.

On the other hand, there are reasons to be concerned. Currently, NOS is not a topic of any prominence in most US science textbooks and is certainly not included in texts in a systematic and explicit fashion. It is unclear what new teachers need to know and be able to do with respect to NOS leading to concern that they may simply ignore this content. Only with strong curriculum models aligned to the NOS content in the *NGSS* and shared examinations that include a strong NOS component will the promise offered by robust inclusion of NOS become a reality.

The inescapable conclusion is that the history and philosophy of science must be a strong part of science teacher preparation, must be included in standards in a clear and robust fashion, must be featured in an engaging fashion in textbooks, and must be assessed on science exit examinations. With these challenges in mind, there is hope that the nature of science will take its place along with traditional science content as a vital part of the science learning experience for the next generation of US science learners.

Acknowledgments The author appreciates the many helpful suggestions offered by the anonymous reviewers. In addition the author acknowledges the extraordinary work of colleagues Drs. Carole Lee and Sophia Sweeney who helped to prepare the state-by-state NOS comparisons, Dr. Feng Jiang who assisted with the analysis of the new *Framework* using a specially designed computer model to discover incidences of NOS in text, and Dr. Lisa Wood who made important contributions to the section on teacher preparation standards as they relate to the inclusion of the nature of science. Needless to say, all errors, interpretations, opinions, and conclusions are the responsibility of the author.

McComas is the inaugural holder of the Parks Family Endowed Professorship in Science Education at the University of Arkansas where he directs the Project to Advance Science Education (PASE). This follows a career as a biology and physical science teacher in suburban Philadelphia and professorship at University of Southern California. He has earned B.S. degrees in Biology and Secondary Education, M.A. degrees in Biology and Physical Science, and the Ph.D. in Science Education from the University of Iowa. McComas has served in leadership roles with the National Science Teachers Association, the International History, Philosophy and Science Teaching Group, the National Association of Biology Teachers, and the Association for Science Teacher Education. McComas is a recipient of the Outstanding Evolution Educator and Research in Biology Teaching awards, the Ohaus award for Innovations in College Science Teaching, and the ASTE Outstanding Science Teacher Educator award. He has written and edited several books including The Nature of Science in Science Education: Rationales and Strategies, numerous book chapters, and articles and has given more than 100 keynote speeches, workshops, and presentations at public events and professional meetings in the United States and in more than a dozen other countries. Most recently, he was a Fulbright Fellow at the *Centre for the Advancement of Science and Mathematics Teaching and Learning* at Dublin City University, Ireland.

Chapter 62
The History and Philosophy of Science in Science Curricula and Teacher Education in Canada

Don Metz

62.1 Introduction

In Canada, the contributions to the field of history and philosophy of science (HPS) and the role and influence of HPS and science education have a rather recent, but significant, history. In the last few decades, we find influential philosophers such as Mario Bunge, Ian Hacking, and Paul Thagard; noted historians of science such as Stillman Drake; and influential science educators like Derek Hodson, Jacques Désautels, Glen Aikenhead, Arthur Stinner, Stephen Norris, and Kieran Egan (and many more, too numerous to mention) providing a diverse and extensive collection of books, essays, journals, lectures, conference keynotes, and graduate students in the field of HPS.

Indeed, many of these Canadian academics have enjoyed a wide range of international success and recognition. Mario Bunge, still active in his 90s, alone has contributed over 80 books and 400 journal articles in his tenure including his oft-referenced eight-volume *Treatise on Basic Philosophy* (1974–1989). Ian Hacking, well known for his defense of entity realism, wrote the introduction to Feyerabend's (1975) "*Against Method*," and Stillman Drake is universally considered to be the authority on Galileo, publishing over 130 books and articles on the great master (Buchwald and Swerdlow 1993, p. 663). More recently, Paul Thagard has emerged as a leader in the field of philosophy and cognitive science (Thagard 2010[1]). In the field of science education, Derek Hodson gave us the influential "Towards a Philosophically More Valid Science Curriculum" (Hodson 1988) and recently published *Towards Scientific Literacy: A Teachers' Guide to the History, Philosophy and Sociology of Science* (Hodson 2008). Nadeau and Désautels (1984) advanced an

---

[1] Note that Thagard (2010) is just the most recent of many books in philosophy and cognitive science by Paul Thagard.

M.R. Matthews (ed.), *International Handbook of Research in History, Philosophy and Science Teaching*, DOI 10.1007/978-94-007-7654-8_62,

epistemological perspective, and Glen Aikenhead provided an often-used research instrument on the Views on Science, Technology, and Science (Aikenhead and Ryan 1992) and has worked extensively in the last number of years arguing for a cultural component in science education. Arthur Stinner's Large Context Problems are widespread and cited by many (Stinner 1995), and Stinner's dramatizations are well known at the conferences of the International History and Philosophy of Science and Science Teaching organization. Additionally, in terms of scientific literacy and its connections to literacy, we find significant contributions from Stephen Norris (Norris et al. 2005), and in terms of narrative and story structuring, Kieran Egan has argued that language and reality develop with a constant interaction using intellectual tools of metaphor, imagery, and binary structuring (Polito 2005).

It is always somewhat risky to highlight so few examples of HPS in your own country when many more contributions to conferences (three of the ten IHPST conferences have been hosted in Canada), journals (editors like Ian Winchester), books (Roth and Desautels 2002), countless journal articles, and contributions in the field of curriculum can be found. However, to the reader, I provide these brief references to provide a context in which I can lay the foundations of a review of HPS in science curricula and teacher education in Canada.

Education in the Canadian political system is a provincial responsibility. Given a geographically expansive country, a diversity of cultures, and ten provinces and three territories, the role of history and philosophy of science (HPS) in science education varies considerably across the nation. In this chapter, I will explore a wide range of aspects of HPS and the teaching of science in Canada. Some of these aspects will include the evolution of ideas surrounding Science, Technology, and Society (STS) and a move towards scientific literacy and "Science for All." These features include the historical underpinnings of the history and philosophy of science and science curricula, the influence HPS has had on national and provincial curriculum from the process/product debates of the 1960s to the national conversations surrounding the 1993 Victoria Declaration (CMEC 1999), and the 1997 Pan-Canadian protocol (CMEC 1997). Additionally, I will address the inclusion of HPS in teacher education programs (including some best practices) and some recent developments. Finally, some time will be taken to examine the status of local indigenous knowledge, specifically its integration in science curriculum in the province of Saskatchewan.

62.2 Historical Perspectives

An early reference to the inclusion of HPS in curriculum in Canada can be found in a memorandum that was signed in 1962 by many prominent mathematicians in the United States and Canada.[2] Among other things the memorandum called for as a fundamental principle a genetic method:

> **Genetic method**. "It is of great advantage to the student of any subject to read the original memoirs on that subject, for science is always most completely assimilated when it is in

---

[2] On the Mathematics Curriculum of the High School, The Mathematics Teacher of March 1962, American Mathematical Monthly of March 1962

> then ascent state." wrote James Clerk Maxwell. There were some inspired teachers, such as Ernst Mach, who in order to explain an idea referred to its genesis and retraced the historical formation of the idea. This may suggest a general principle: The best way to guide the mental development of the individual is to let him retrace the mental development of its great lines, of course, and not the thousand errors of detail. (Ahlfors et al. 1962, p. 426)

Two Canadians signed the memorandum, the prominent geometer H. S. M. Coxeter, from the University of Toronto, and a relatively new Canadian Alexander Wittenberg, from Laval University. Coxeter was very active in the Upper Canada Branch of the Canadian Society for the History and Philosophy of Science for many years. As well, the Canadian Mathematical Bulletin reported in 1963 that Wittenberg was appointed as a professor of mathematics at York University in Toronto. At this time, York was in the process of developing courses to relate mathematics to the humanities and social sciences as well as the natural sciences. Wittenberg was to initiate this venture by developing a first year course in mathematics and philosophy. Hayo Siemsen (2011), tracing the influences of Ernest Mach in science education, notes the strong connections of Wittenberg to such notable professors as Pólya and Nevanlinna, and he argues convincingly about the influence that Mach had on science education (quite an obvious influence on Wittenberg it seems from the inclusion of the genetic method in the aforementioned memorandum). Siemens further suggests that is was Wittenberg who provided Freudenthal with the initial ideas leading to the PISA study (see Wittenberg 1965, 1968; Siemsen and Siemsen 2008, 2009). Wittenberg could then be considered to be an early pioneer in Canada promoting the inclusion of HPS. However, Wittenberg unfortunately died at an early age and published very little. The reality is that he had very little influence and is essentially unknown in the country because of his early demise. The genetic method, a historical approach to knowledge, had no influence in curriculum developments and remained for the most part and academic argument.

In most developed countries, the science curriculum, often referred to as "school science" (Duschl 1994), generally provides a wide breadth of coverage intended to prepare students for postsecondary science courses acting as a "pipeline" to future studies (Millar and Osborne 1998). Glen Aikenhead (2003), tracing the origins of school science in the Western tradition, notes that traditional science curriculum "assumes that 'science' in 'school science' has the same meaning as it has in, for example, 'the American Association for the Advancement of Science'" (p. 3). That is, the science curriculum is essentially a nineteenth-century curriculum in scope and intent.

The Canadian curriculum for the first half of the twentieth century generally followed this model with a great emphasis on the training of scientists and engineers in the 1960s and 1970s fueled by international competition and the space race. In reflection, Rutledge (1973) notes "The concern was also expressed that too little emphasis was being given to the philosophy and processes of science and that meaningful laboratory work was not an important part of most school science" (p. 600). However, emerging from these concerns, a large number of curriculum resources were produced that mostly focused on the processes of science. Many of these resources such as Science: A Process Approach (AAAS 1967), Science Curriculum Improvement Study (SCIS 1972), Elementary Science Study (EDC 1969), Physical Science Study Committee (PSSC 1960), Chemical Education

Material Study (CEMS 1960), Biological Sciences Curriculum Study (BSCS 2006), Earth Science Curriculum Project (Heller 1964), and Introductory Physical Science Program (ESI) found their way into Canadian science curricula. As elsewhere, the need for scientists was considered essential, and although it was generally accepted that all students needed to be "scientific literate," this literacy was oriented towards investigations, observation, learning of abstract concepts, and the acquisition of knowledge as though the student had discovered it. In general, weaknesses identified in these approaches were a failure to meet the needs of the general student population, readability levels were usually above the grade level, and most experiments and investigations were close ended rather than open ended (Baptiste and Turner 1972). Others argued that "there was no basis in school science on which to develop a critique of the role science plays in society or an appreciation of its strengths and limitations" (Fensham 1973, cited from Fensham 1997, Reconsidering Science Learning, p. 22).

With the advent of curricula that focused on the preparation of scientists, criticism began to emerge at that time that questioned why the only students worthy of curricular attention were those who might become professionals. Questions concerning "science for whom?", the balance of content and process, the relevance of the curriculum, and the emphasis on the transmission model of instruction were beginning to be asked by many educators and scientists themselves.

As an effort to address the relevance of science curriculum, the early development of a humanistic alternative to school science could be found in Science, Technology, and Society (STS) programs formally initiated in the late 1960s, in the United States, United Kingdom, Australia, and the Netherlands (Aikenhead 2003; Solomon and Aikenhead 1994). Aikenhead argued that "These university academic programs responded to perceived crises in responsibility related to, for instance, nuclear arms, nuclear energy, many types of environmental degradation, population explosion, and emerging biotechnologies. Thus, social responsibility for both scientist and citizen formed one of the major conceptions on a humanistic perspective in school science" (p. 8).

The dichotomy of purposes of science education, that is, science for future scientists versus a more humanistic approach for scientific literacy, helped fuel debates about the purposes of science education in the country. For example, the introduction of an STS orientation of high school science courses was not well received by university faculty. In some provinces, STS science courses were not approved for university entrance.

An important step in examining the various viewpoints in science education was initiated in the 1980s by the Science Council of Canada (SCC). The SCC was created by the federal government in 1966 to advise the government on science and technology policy (Millin and Steed 2012). The SCC members were broadly representative of the Canadian scientific community, in both the academic and private sectors. Consisting of a panel of 30 experts from the natural and social sciences and from business and finance, they produced many published works which were qualified by the council for reliability and methodology. In some cases, these reports provided recommended actions to governments or other institutions. However, the reports were most often intended to create a climate for policy debate rather supporting specific guidelines for government action.

In order to foster dialogue in science education, the SCC undertook a series of four discussion papers for a study of Canadian science education in the early 1980s. As noted by Hugh Munby (1982), one of the objectives was "to stimulate active deliberation concerning future options for science education," suggesting that the Science Council had no collective view on a direction for science education in Canada and in order to develop such a view, it was soliciting a variety of viewpoints.

The position papers were "A Canadian Context for Science Education" by James Page (1980) who argued that science education could contribute to "improved national awareness." A second paper by Glen Aikenhead (1980), "Science in Social Issues: Implications for Teaching," supported the view that science should be taught such that students learn about social and political issues. A third paper, "An Engineer's View of Science Education," by Donald George (1981) advocated for the equal treatment of the engineer's intellectual processes, and the final paper of the series, "What is Scientific Thinking?," by Hugh Munby (1982) examined what it meant to think critically and scientifically. The SCC's work culminated with an extension research program which included examination of the science curriculum guidelines in every province and territory, an analysis of common textbooks, survey of teachers and students, and case studies of science teaching across the country. Additionally, 11 conferences attended by ministry officials, school board members, teachers, students, and representatives from university, labor, and industry helped produce a consensus which endorsed a position of "Science for All" (SCC 1984).

The SCC report 36, "Science for Every Student: Educating Canadians for Tomorrow's World," established a goal of scientific literacy for all with four broad aims:

To encourage full participation in a technological society
To enable further study in science and technology
To facilitate entry to the world of work
To promote intellectual and moral development of individuals

Among the 47 recommendations, we find a recommendation to incorporate a science-technology-society emphasis in science courses at all levels and a recommendation to "ensure that courses at all levels present a valid representation of the nature of science and scientific activity through the judicious use of examples from the history of science" (p. 48).

While these recommendations perhaps fostered some debate, there is little evidence that they influenced provincial or national curriculum at the time (except perhaps by the individuals locally). Arguably, it was the slow process of curriculum development and not the debate that was most influential. Curriculum development in Canada is usually marked by major overhauls in 20-year (approximately) intervals. At this time, any significant changes would have to wait.

Around the same time as the SCC report, The National Science Teachers' Association adopted Science, Technology, and Society (STS) as its official position for science education (Yager 1993, p. 145). Many other countries also developed resources to address teaching of STS. For example, in the United Kingdom, we find Science in a Social Context (Solomon 1983), and in Canada, SciencePlus (ASCP 1988) was developed in Atlantic Canada and used across various provinces. As ideas around STS, STSE (adding the Environment), and socioscientific issues began to evolve, the Canadian context, especially in terms of the intended curriculum, began to advance towards a more national viewpoint. Aikenhead (2000), following the work of Rosenthal (1989) and Ziman (1984), illustrates two types of social issues in STS science that began to envelope the views of most science educators:

1. Social issues *external* to the scientific community ("science and society" topics, e.g., energy conservation, population growth, or pollution)
2. Social aspects of science – issues *internal* to the scientific community (the sociology, epistemology, and history of science, e.g., the cold fusion controversy, the nature of scientific theories, or how the concept of gravity was invented)

Aikenhead also noted that these views would be flexible enough to embrace the different goals and content found the curricula across different provinces. Ultimately, these dual issues began served as a major influence in the development of the Pan-Canadian Framework's STSE emphasis.

Today, many Canadian educators continue work on these STSE issues, in both external[3] and internal aspects of STS science.[4]

62.3 Pan-Canadian Science Framework

Generally, provincial curricula in Canada have been developed through the years independently by each province with varying degrees of cooperation. No national curriculum existed in any form. As a result, a considerable amount of disparity and unnecessary duplication of effort existed among the provinces. Moreover, families moving from one part of the country to another were often caught in a curriculum mismatch with children repeating some content while completely missing other topics.

Recognizing that with increased mobility of Canadians, a more coordinated effort would help harmonize the curriculum nationally and provide some economies of scale, the Provincial Ministers of Education (Canadian Ministers of Education of Canada (CMEC)) agreed on the Victoria Declaration in 1993 identifying education as lifelong learning and highlighting the need for national curriculum compatibility (Milford et al. 2010). The CMEC established the Pan-Canadian Science Project as the first national curricular effort, culminating with the development of the *Common Framework of Science Learning Outcomes* (CMEC 1997). The framework was intended as a guide for provinces to develop their own curriculum based on the framework, giving some degree of

---

[3] For example, see Yore (2011), Pedretti (1997), Pedretti et al. (2008), Pedretti and Hodson (1995), Sammel and Zandvliet (2003), and Bencze (2010).

[4] For example, see Norris and Phillips (2003), Stinner (2003), and Klassen (2006).

commonality between the provincial jurisdictions. In reference to the development of the framework, Aikenhead (2000) writes:

> In keeping with Canadian culture, the *Common Framework of Science Learning Outcomes* (the *Framework*) evolved through negotiation and compromise among provincial bureaucrats, advised by interested parties (stakeholders) in each province. This political process, however, did not meet the standards of curriculum policy development held by the Canadian science education academic community. (p. 51)

Aikenhead, who was instrumental in the previous debates more than a decade earlier on the nature of science education promoted by the Science Council of Canada (SCC), contrasted the processes followed by the CMEC and SCC. He noted that the SCC conducted educational studies "with the highest of scholarly standards," while the CMEC allowed the provincial civil servants, many with little expertise or research knowledge in field of study they were addressing, to complete the framework. Many science educators, originally recruited as consultants intended to provide input at the national level, were relieved of their responsibilities when some provinces did not want to fund equal participation. In other words, participation was reduced to the lowest common denominator.

However, as Aikenhead also noted, some of the conclusions of the SCC science education study in the early 1980s did find their way into the CMEC's bureaucratic negotiations and development of the framework. Additionally, other international documents such as the US National Research Council's *Standards* (NRC 1996) and Project 2061 (AAAS 1989) were significant influences. By the late 1990s the framework, with a major emphasis on STSE goals, became a set of guidelines for science curricula across the country.

A critique of the framework, which in the author's opinion suffers greatly as compendium of fragmented outcomes, is beyond the scope of this paper. However, within the framework, many outcomes with respect to the history and nature of science begin to emerge in Canadian science education for the first time and merit mention here. The framework takes the position that the promotion of students' scientific literacy requires students' understanding of HPS and the nature of science (NOS) for rational and scientific decision making in an everyday context.

As a vision for scientific literacy, four foundation statements were established for this framework:

1. Science, Technology, Society, and the Environment (STSE)
2. Skills
3. Knowledge
4. Attitudes

It is within the STSE foundation that we find explicit mention of the nature of science (although it is always coupled with technology, i.e., "the nature of science and technology"). The STSE foundation focuses on three major dimensions: the nature of science and technology, the relationships between science and technology, and the social and environmental contexts of science and technology. Table 62.1 highlights the HPS and NOS attributes that are found in the description of the STSE foundation.

Table 62.1 HPS and NOS attributes

Nature of science and technology
Science is a human and social activity with unique characteristics and a long history that has involved many men and women from many societies. Science is also a way of learning about the universe based on curiosity, creativity, imagination, intuition, exploration, observation, replication of experiments, interpretation of evidence, and debate over the evidence and its interpretations. Scientific activity provides a conceptual and theoretical base that is used in predicting, interpreting, and explaining natural and human-made phenomena. Many historians, sociologists, and philosophers of science argue that there is no set procedure for conducting a scientific investigation. Rather, they see science as driven by a combination of theories, knowledge, experimentation, and processes anchored in the physical world. Theories of science are continually being tested, modified, and improved as new knowledge and theories supersede existing ones. Scientific debate on new observations and hypotheses that challenge accepted knowledge involves many participants with diverse backgrounds. This highly complex interplay, which has occurred throughout history, is fuelled by theoretical discussions, experimentation, social, cultural, economic, and political influences, personal biases, and the need for peer recognition and acceptance
While it is true that some of our understanding of the world is the result of revolutionary scientific developments, much of our understanding of the world results from a steady and gradual accumulation of knowledge
Social and environmental contexts of science and technology
The history of science highlights the nature of the scientific enterprise. Above all, the historical context serves as a reminder of the ways in which cultural and intellectual traditions have influenced the questions and methodologies of science and how science in turn has influenced the wider world of ideas

The framework itself is organized into general learning outcomes (GLOs), which are established for each foundation. General learning outcomes are broad statements of what students are expected to learn and be able to do. Table 62.2 shows the GLOs for the STSE foundation, many of which address HPS, STSE, and NOS outcomes.

In turn, the GLOs are delineated into several specific learning outcomes (SLOs). The GLOs and SLOs are then linked to specific learning outcomes in the knowledge foundation (the SLOs are not shown here). Each GLO in Table 62.2 has a similar path that can be traced to knowledge outcomes. Sometimes the GLO is represented in more than one outcome, and sometimes it may not be represented at all. One should note that the curriculum remains organized in the traditional way in terms of knowledge outcomes. While the inclusion of the nature of science outcomes should be seen as encouraging progress, the outcomes are scattered across a wide range of knowledge outcomes. In conclusion, we can say that in terms of promoting HPS in the science curriculum, we see for the first time in Canada a set of general and specific learning outcomes. While this is a very positive development, these outcomes are fragmented and dispersed without any clear connections to any overall perspective on the nature of science. In other words, we now have HPS and NOS outcomes, but there is no coherent approach to teaching of the nature of science.

Table 62.2 General learning outcomes (GLO) for the STSE foundation

It is expected that students will…	
109	Describe various processes used in science and technology that enable us to understand natural phenomena and develop technological solution
110	Describe the development of science and technology over time
111	Explain how science and technology interact with and advance one another
112	Illustrate how the needs of individuals, society, and the environment influence and are influenced by scientific and technological endeavors
113	Analyze social issues related to the applications and limitations of science and technology, and explain decisions in terms of advantages and disadvantages for sustainability, considering a few perspectives
114	Describe and explain disciplinary and interdisciplinary processes used to enable us to understand natural phenomena and develop technological solutions
115	Distinguish between science and technology in terms of their respective goals, products, and values, and describe the development of scientific theories and technologies over time
116	Analyze and explain how science and technology interact with and advance one another
117	Analyze how individuals, society, and the environment are interdependent with scientific and technological endeavors
118	Evaluate social issues related to the applications and limitations of science and technology, and explain decisions in terms of advantages and disadvantages for sustainability, considering a variety of perspectives

62.4 HPS Outcomes in Provincial Curriculum: Ontario

We also must remember at this point that the framework is intended as a guideline and each province may (or may not) adapt the curriculum in their own way. Indeed, this is exactly what has happened. For example, the Ontario (Canada's largest province) curriculum organizes expectations for the grades 11 and 12 science courses in five strands that are intended to "where possible" align with the topics set out in the *Pan-Canadian Common Framework of Science Learning* Outcome (CMEC 1997). Table 62.3 shows how an HPS outcome can be traced to the Ontario provincial curriculum implementation from the vision present in the framework to the implementation aligned with specific knowledge outcomes. The GLO (general learning outcome) (GLO – 114), "Describe and explain disciplinary and interdisciplinary processes used to enable us to understand natural phenomena and develop technological solutions," has nine specific learning outcomes in the framework

Table 62.3 Tracing an HPS outcome to provincial curriculum

Vision

Science is a human and social activity with unique characteristics and a long history that has involved many men and women from many societies

General learning outcome (GLO – 114)

Describe and explain disciplinary and interdisciplinary processes used to enable us to understand natural phenomena and develop technological solutions

Specific Learning Outcome (SLO – 114.x)

114-1

Explain how a paradigm shift can change scientific worldviews

114-2

Explain the roles of evidence, theories, and paradigms in the development of scientific knowledge

114-3

Evaluate the role of continued testing in the development and improvement of technologies

114-4

Identify various constraints that result in trade-offs during the development and improvement of technologies

114-5

Describe the importance of peer review in the development of scientific knowledge

114-6

Relate personal activities and various scientific and technological endeavors to specific science disciplines and interdisciplinary studies

114-7

Compare processes used in science with those used in technology

114-8

Describe the usefulness of scientific nomenclature systems

114-9

Explain the importance of communicating the results of a scientific or technological endeavor, using appropriate language and conventions

Life science	**Chemistry**	**Physics**	**Earth science**
114-2	*114-2*	*114-2*	*114-2*
Explain the roles of evidence, theories, and paradigms in the development of scientific knowledge (e.g., explain how the cloning of a sheep in 1997 affected the scientific theory of differentiation)	Explain the roles of evidence, theories, and paradigms in the development of scientific knowledge (e.g., explain how bonding theory can help one understand certain colligative properties)	Explain the roles of evidence, theories, and paradigms in the development of scientific knowledge (e.g., explain the role of evidence and theories in the concept of fields)	Explain the roles of evidence, theories, and paradigms in the development of scientific knowledge (e.g., describe the historical development of theories to explain the origin of the universe)

document as shown in Table 62.3. I show how one of these, 114-2, “explain the roles of evidence, theories, and paradigms in the development of scientific knowledge,” can be found in a knowledge outcome for each science course, biology, chemistry, earth science, and physics, at the secondary level (from the framework). Table 62.4

Table 62.4 HPS at the provincial level (GLO 114-2)

Life Sciences	The Ontario expectation is virtually exactly the same as the framework
Earth Science	The Ontario intent is the same but the wording is different, i.e., "describe origin and evolution of the Earth and other objects in the solar system"
Chemistry	There is no corresponding outcome in Ontario
Physics	The Ontario intent is the same but specific reference to models and evidential examples are provided

describes how the outcome appears in the Ontario curriculum. It is possible, although somewhat challenging and time-consuming, to trace each GLO and SLO to a knowledge outcome.

Thus, we can see that for the most part the nature of science outcomes as described in the framework is making its way into the provincial curriculum documents. Although some of the outcomes may be omitted, we can find many outcomes that have actually been enhanced, and even new outcomes emerge as they may relate to local interests. For example, our physics outcome becomes in Ontario:

> explain how the concept of a field developed into a general scientific model, and describe how it affected scientific thinking (e.g., explain how field theory helped scientists understand, on a macro scale, the motion of celestial bodies and, on a micro scale, the motion of particles in electromagnetic fields). (Ontario 2000, p. 108)

And in terms of local interest, we can find outcomes such as:

> describe advances in Canadian research on atomic and molecular theory (e.g., the work of Richard Bader at McMaster University in developing electron-density maps for small molecules; the work of R.J. LeRoy at the University of Waterloo in developing the mathematical technique for determining the radius of molecules called the LeRoy Radius). (Ontario 2000, p. 65)

We must see the adoption of these types of outcomes as a positive step in promoting an understanding of HPS in science curriculum and as a step towards achieving many of the claims of the HPS community of the benefits of using an HPS approach in science education (Matthews 1994; Winchester 1989). However, the inclusion of the HPS outcomes still remains mostly ad hoc and fragmented without any internal consistency in the science programs. Such consistency can be found in independent courses in philosophy that are offered through such programs as the International Baccalaureates (IB) and as stand-alone courses such as teaching philosophy in high school. These courses, worthwhile and generally taught with some expertise, are offered as electives and usually found as "gifted and talented" offerings in some jurisdictions.

This emergence of a coherent curriculum in philosophy (albeit more general), the growing acceptance of philosophy as a teaching major or minor in more provincial jurisdictions, and the organization of teachers associations such as the Ontario Philosophy Teacher's Association should be seen as positive force in the future for the continued development of the inclusion of HPS in curriculum in general and in science education specifically. Arguably, Canadians who support an HPS perspective are pleased with the progress, albeit flawed in many ways. However, we should take our pleasure with some caution.

62.5 HPS Outcomes in Provincial Curriculum: Saskatchewan

Contrasting the Ontario use of the Pan-Canadian Framework is the recent development of the Saskatchewan science curriculum. The province of Saskatchewan is in Western Canada and has a population of just over one million persons with approximately 16 % Indigenous and Métis people. The vision for science education in the province is stated in the Saskatchewan Learning Science 9 Curriculum Guide:

> The aim of K-12 science education is to enable all Saskatchewan students to develop scientific literacy. Scientific literacy today embraces Euro-Canadian and Indigenous heritages, both of which have developed an empirical and rational knowledge of nature. A Euro-Canadian way of knowing about the natural and constructed world is called science, while First Nations and Métis ways of knowing nature are found within the broader category of Indigenous knowledge (Hounjet et al. 2011). (Sask Science 9, p. 5)

The Saskatchewan curriculum delineates the foundations of the Pan-Canadian Framework from a cultural perspective. For example, traditional and local knowledge is included alongside of life, physical, earth, and space science knowledge. Scientific knowledge is represented as a set of understandings, interpretations, and meanings that are part of cultural complexes that encompass language, naming and classification systems, resource use practices, ritual, and worldview. Indigenous knowledge is represented as a set of understandings, interpretations, and meanings that belong to a cultural complex that encompasses language, naming and classification systems, resource use practices, ritual, spirituality, and worldview (note: the difference is spirituality).

The Saskatchewan curriculum emphasizes cultural perspectives throughout all of their science documents stating that:

> Students should recognize and respect that all cultures develop knowledge systems to describe and explain nature. Two knowledge systems emphasized in this curriculum are First Nations and Métis cultures (Indigenous knowledge) and Euro-Canadian cultures (science). In their own way, both of these knowledge systems convey an understanding of the natural and constructed worlds, and they create or borrow from other cultures' technologies to resolve practical problems. Both knowledge systems are systematic, rational, empirical, dynamically changeable, and culturally specific. (SASK Science 9, p. 20)

The cultural perspective is carried through to the general and specific learning outcomes often in terms of identifying and/or comparing and contrasting cultural perspectives. For example, in grade 9 science, we find curriculum outcome RE9.4 "Analyze the process of human reproduction, including the influence of reproductive and contraceptive technologies" (p. 32). An indicator of achievement is given as "Acknowledge differing cultural perspectives, including First Nations and Métis perspectives, regarding the sacredness, interconnectedness, and beginning of human life" (p. 32). The achievement of these outcomes is also carried through the recommended textbook, Saskatchewan Science 9, developed especially for this curriculum. First Nations and Métis content, perspectives, and ways of knowing are an integral part of the Saskatchewan science textbook. For example, the social and cultural perspective in the section on contraception states, "All cultures and religions have moral and ethical beliefs surrounding reproduction and contraception. There are also different beliefs about when exactly a fertilized egg is considered to be a person. For this reason, some methods of contraception are considered to be the ending of a human life" (p. 103). In another section on chemical change, a cultural perspective is given as "Some medicine women would go on a fast for several days during which time they would meditate on the medicines and plants they would mix to create the desired effects. Certain families have spiritual understanding to mix medicines for heart disease, diabetes, hepatitis, and other illnesses" (p. 140). The textbook does not just pay "lip service" to cultural perspectives, but integrates differing viewpoints, Elder's wisdom, and traditional knowledge throughout all units. It should be noted that in no way does the textbook shy away from an open and clear discussion of controversial topics in science such as contraception. Given the recent publication of the textbook series, it remains to be seen how it will be accepted by students, teachers, parents, and other stakeholders.

As widely noted in educational circles, we have an intended curriculum and an implemented curriculum. Teachers remain the final filter in the delivery of any curriculum, and their professional development and preservice preparation is an important factor in the actual achievement of these outcomes in the classroom. This point reflects the practical orientation of the teaching field and what they value or at least what they believe schools and stakeholders value. Interestingly, in a study conducted by the SCC in 1980, a survey of over 4,000 science teachers in Canada ranked the importance of objectives in science education. Out of 14 different objectives, the number one was "understanding scientific facts, concepts and laws" and number 14 was "understanding the history and philosophy of science." Many teachers hold preconceptions about teaching science from their own experiences, from their preservice education experiences, and from their own teaching experiences (Duffee and Aikenhead 1992). Aikenhead suggests that "a simple in-service intervention by itself holds little promise for altering a teacher's acceptance of STS science" and argues that in addition to changing deep-seated values and images of teaching science, teachers must add new methods to their repertoire of instructional strategies. However, his recommendation that new routines of instruction are best learned from fellow teachers means we must provide meaningful preservice instruction to develop these teachers. In the next section, I'll outline a couple of exemplars oriented towards developing new "routines of instruction" in preservice teachers.

62.6 Teacher Education

Teacher education and certification in Canada is governed by each provincial or territorial agencies through regulations established by colleges of teachers and/or ministries of education. At the university level, teacher education programs must be designed to meet these specific requirements in terms of required coursework and practical teaching experience. Teacher education programs in Canada generally have two forms: an integrated program or an after-degree program.[5] In the integrated program students enter directly into a faculty of education and take subject area courses at the same time as they take education courses. Typically, the majority of the education courses can be found in the final 2 years of the program; at this time students complete an in-school practicum which varies in duration from province to province. In after-degree programs, students first complete a degree and then enter a 12-month or a 24-month education program (depending on provincial requirements). In both the integrated and after-degree programs, students typically finish with two degrees, a subject area general bachelor degree and a bachelor of education degree (although some programs may vary).

In terms of course offerings, students in education programs will take courses in educational psychology, teaching methodology, literacy, aboriginal education, special education, plus curriculum, instruction, and assessment in their teaching specialties. Teacher programs, in both the integrated and after-degree format, can be very crowded places in terms of compulsory requirements that vary from province to province. Some education professors across the country who maintain an interest in HPS may be found to include the nature of science as a lecture or topic in their methods courses. However, it is unusual to find a course offering in the history and philosophy of science and science teaching at the undergraduate level.[6] Therefore, I offer here two exemplars in teaching the history and philosophy of science and science teaching that is required at the undergraduate level. The first is a course for secondary preservice science teachers who have a major or minor specialty in the sciences. The second exemplar is a course for nonspecialist middle-year teachers.

62.6.1 HPS for Secondary Science Teachers

The history and philosophy of science and science teaching course, developed and taught by the author, is offered at the University of Winnipeg and is compulsory for all students with a double science major/minor. The course can also be taken as an elective by other interested students. The course has essentially three components, philosophical perspectives in science, teaching strategies for HPS, and a historical case study (Stinner et al. 2003). Using a seminar format, students examine, chapter by chapter, John Losee's (1993) book, *Introduction to the History and Philosophy of Science*. Losee contends that the philosopher of science seeks answers to such questions as:

What characteristics distinguish scientific inquiry from other types of investigation?
What procedures should scientists follow in investigating nature?

---

[5] There are many variations of these programs across the country, including specialized access programs.

[6] It is possible from time to time to find graduate courses that relate specifically to HPS themes. For example, Derek Hodson offered a graduate course, Curriculum Making in Science: Considerations in the History, Philosophy, and Sociology of Science.

What conditions must be satisfied for a scientific explanation to be correct?
What is the cognitive status of scientific laws and principles?

Providing a commentary on original works from Aristotle to Van Frassen (and everyone in between), Losee's approach is appropriate for the undergraduate student and provides an insight into the major questions in the philosophy of science. Following the grounding in the philosophy of science, a number of teaching strategies are examined including the implementation of historical experiments, storytelling, debates, and a variety of differentiated instruction strategies (Metz et al. 2007). Students complete their own case study that traces the historical development of a scientific idea and design a plan to implement instruction in a science class. Case studies over the years have included all of the major ideas in science such as the development of the models of the atom and the cell and the history of pasteurization. However, many creative, unique, and interesting case studies have also been developed that include the history of the pacemaker, birth control, the story of blood, play doh, and climate change.

62.6.2 HPS for Nonspecialist Middle-Year Science Teachers

In teacher education programs in Canada, preservice middle-year programs typically follow a set of standard courses in content area pedagogy. As generalists, these teachers are faced with teaching a broad range of subjects with a core of language arts, social studies, mathematics, and science. Students, who enter these programs, overwhelmingly, have a background in the humanities. Very few students have a background in mathematics and science, and their self-efficacy in teaching these subjects is generally low.

As a model program incorporating HPS, I will outline here a middle-year science methods course initiated by Brian Lewthwaite at the University of Manitoba (Lewthwaite 2012). Recognizing that their teacher candidates viewed science as primarily a body of knowledge and not a process of inquiry, they use the nature of science as a pedagogical framework to assist their students in developing a more authentic view of science:

> More importantly, we believe it has the potential to assist teacher candidates in developing a positive self-image of themselves as teachers of science because their role is focused more on an understanding of the pedagogical processes to be employed in science instruction rather than, simply, their content knowledge. (Lewthwaite 2012)

In their course, suitable topics are identified for students to teach in their practicum experience that follows the course. The course instructor would then present a historical account of the development of understanding associated with the topic under consideration in a 1-h presentation. Following the presentation, the students were asked to consider the nature of science (NOS) attributes embedded within the historical context. Next, the student teachers, working in pairs, planned three linked authentic science lessons that addressed the topic to be taught. The students were required to use their understanding of the nature of science as a rationale for the task orientation taken in the lesson. Following the course, students participate in a 5-week teaching practicum where they co-teach their lessons. In a post-teaching reflection, the students are required to identify at least five nature of science characteristics that they believed informed the development of their lessons and their teaching of science. Additionally, the students critiqued their own lessons and reported on how these attributes resulted in positive learning experiences for their students.

Initial results of this innovative program have been very positive (Lewthwaite 2012). Their students speak of transformative experiences viewing science as a human activity, focusing on educational goals that are social and personal and an instructional emphasis that is more process oriented. The authors make a strong claim that NOS must not just be an ad hoc component of a science methods course for middle-year teachers but that

> NOS needs to be the foundation upon which teacher education science courses should be premised, especially in using the human story of science as vignettes for teacher candidates to come to an appreciation of what science is. (Lewthwaite 2012)

62.7 Conclusion

Canada, as a country, is geographically very expansive and culturally highly diverse. In many ways, it is difficult for outsiders to imagine how the nation brings such a diverse set of ideas together into a national perspective. In reality, we never do. Within the most recent round of curriculum renewal, provinces interpret and implement the national standards in their own, sometimes unique, ways.

It is clear from our review of HPS perspectives in Canadian curriculum and teacher education that we have made significant progress in enabling the inclusion of HPS perspectives in science education today. A great deal of attention is being given, especially in the academic community, to STSE and sustainable initiatives. Additionally, cultural perspectives, especially as noted in the province of Saskatchewan, are being integrated in a significant manner. However, it is also evident that more work needs to be done to prepare teachers to teach STS, HPS, and cultural perspectives such that the intended curriculum more closely matches the implemented. Most elementary and middle-year school teachers still have little science background, and most teachers still give low priority towards teaching the more subtle aspects of HPS. Unfortunately, knowledge content is still the emphasis in science education today dominated by teacher-directed instruction and motivated in a large part by assessment techniques. As we move forward, we are thankful for the appearance of HPS in national documents and initiating, at least in part, a national discussion.

Further studies are needed to demonstrate the effectiveness of HPS perspectives and the extent to which it can be a guiding principle as advocated by Lewthwaite instead of merely an “add-on” to traditional science instruction. Probably, the most interesting period of curriculum reform lies ahead.

Don Metz is an associate professor in the Faculty of Education at the University of Winnipeg. He holds a B.Sc. in Physics and an M.Ed. and Ph.D. in science education. He has been extensively involved with curriculum writing in Canada, and he has been very active in the professional development of in-service teachers for many years. He has presented at numerous conferences and published papers in a wide variety of education journals including *Teacher Education Journal*, *Science Education, Science & Education*, *The Physics Teacher*, and the *Canadian Journal of Environmental Education*. His current interests include student-generated questions and academic engagement in science, contextual teaching, the use of historical narratives and the interrupted story form, sustainability, and international practicum for preservice teachers.

Chapter 63
History and Philosophy of Science and the Teaching of Science in England

John L. Taylor and Andrew Hunt

63.1 The Years Leading Up to the National Curriculum

Interest in teaching about the history of science and aspects of its philosophy in schools dates back, in the UK, at least as far as the mid-nineteenth century. In his exploration of the claims made for the teaching of the history of science, Edgar Jenkins (1990) quotes from the presidential address at the British Association for the Advancement of Science meeting in Glasgow in 1855. The Duke of Argyll said that what was wanted in the teaching of the young, was 'not so much the mere results, as the methods, and above all, the history of science', if education were to be 'well-conducted to the great ends in view'.

In a review, Michael Matthews (1994/2014) traces the weak and uneven tradition of incorporating the history of science in science education and takes up the story at the start of the twentieth century when, in 1918, a committee chaired by J J Thomson issued a report called *Natural Science in Education* which argued that:

> It is desirable…to introduce into the teaching some account of the main achievements of science and of the methods by which they have been obtained. There should be more of the spirit, and less of the valley of dry bones…One way of doing this is by lessons on the history of science (Cited in Brock (1989, page 31)).

The report went on to say that:

> some knowledge of the history and philosophy of science should form part of the intellectual equipment of every science teacher in a secondary school.

As Mathews has shown, these recommendations were included in the 'Science for All' curriculum that was developed after the First World War. Also in the

interwar years, Percy Nunn, the philosopher of science, Richard Gregory and other historically minded educationalists argued the case for history. Popular science textbooks incorporating these ideas were written by a number of authors including the chemist, E. J. Holmyard. Holmyard argued for a historical approach, not just on motivational or instrumentalist grounds but on cognitive grounds: teaching a topic historically was the only way that the nature of scientific truth could be conveyed.

After the Second World War, the history of science gradually diminished in importance in school science. Science education was subject-focussed and directed towards external examinations controlled by the universities. By modern standards, this was a small-scale business. In 1952 only about 20,000 candidates, aged 16, took O-level Biology with about 15,000 taking O-levels in each of physics and chemistry (ASE 1979). These examinations were taken by a subset of the students attending selective grammar and independent schools which catered for about 25 % of the age cohort.

At that time, most young people attended secondary modern schools and left at the age of 15 with no qualifications in science. However, during the late 1950s and early 1960s, some local authorities began to move away from the selective system and establish comprehensive schools. By the late 1960s, comprehensive secondary education had become a central part of government policy. In the same decade, new regional examination boards were set up to provide the Certificate of Secondary Education in all subjects, including science, for young people who were not able to take O-levels.

Then, in 1972, the school leaving age was raised to 16. From that time on, most students were expected to take CSE or O-level examinations before leaving school or staying on for further education. As a result of these developments, more and more young people chose to study some science throughout their time in secondary school. Subsequently, in 1989, the study of science became a compulsory part of the curriculum with the total number of students gaining science qualifications at the age of 16 exceeding 600,000 per year by the twenty-first century.

The tradition established in selective schools continued to be very influential. In this tradition, school science was regarded as a fixed body of knowledge, related to and derived from real science, which young people need to acquire in order to understand the world they live in and which they must master in order to take their studies of science further (ASE 1979). The persistence of this general approach meant that teaching about the history and nature of science did not enter the mainstream of science education for all in England and Wales until the national curriculum was introduced in 1989 (Department of Education and Science 1989).

The first version of the curriculum was detailed and complex. It was divided into 17 attainment targets (ATs). One of the significant innovations was the seventeenth attainment target, AT17 ‘The nature of science’. The intention of AT17 was that students should study historical case studies to develop their understanding of how scientific theories arise and change through time. They were also expected to explore how the nature and application of scientific ideas are affected by the social and cultural context in which they develop.

None of the ideas in AT17 were new, but for the first time it was compulsory that they should feature in the science courses of most learners. The feasibility of teaching these ideas, and the resources needed for the teaching, had been investigated on a relatively small scale in a series of innovative curriculum projects during the previous three decades starting with the Nuffield projects of the 1960s.

63.2 Nuffield O-Level Sciences in the 1960s

By the mid-1950s, it had become clear to teachers and politicians that secondary science education was in need of major reform. There was dissatisfaction with the emphasis on factual recall in examinations. Chemistry courses focussed on the preparation and properties of elements and compounds, whilst in physics the content was largely confined to the classical themes of nineteenth century science such as electricity and magnetism, heat, light and sound. Biology, as a combination of botany and zoology, was not fully established as a subject for boys as well as girls (Hunt 2011).

Pressure for change arose particularly from activists in the Science Master's Association and Association of Women Science Teachers (organisations which merged to form the Association for Science Education in 1963). Leading teachers from selective schools had built up a consensus that there was an urgent need to modernise both the content of the science curriculum and how it was taught. Much work had been done in the late 1950s to draw up fresh syllabuses.

The problem was that at that time there was no statutory, centralised control of the curriculum. The government did not expect to intervene directly in curriculum matters. As a result, there was no established way to bring about reform and no obvious source of resources to fund the development work. However, after a period of negotiation, the Nuffield Foundation[1] decided to make a very large grant towards the cost of a long-term programme to improve the teaching of school science and mathematics. This was the beginning of a major era of curriculum development

The work began with the Nuffield Science courses to O-level. These were very influential, but their main focus was on practical work carried out by students as the starting point for introducing scientific concepts. Nevertheless these courses did not ignore the tradition of using episodes from the history of science as a context for teaching science. One of the aims of Nuffield Biology,[2] for example, was to present the subject as part of human endeavour showing, with the help of historical examples, that biological knowledge is the product of scientists working in many different parts of the world (Nuffield Foundation 1966a). The course aimed to demonstrate that the science of biology is based not only on observation and experimentation but

---

[1] The Nuffield Foundation website has an account of the charity's involvement in the science curriculum over 50 years: http://www.nuffieldfoundation.org/curriculum-projects

[2] All the original Nuffield Biology publications are available from the National STEM Centre eLibrary at http://stem.org.uk/cxhs

also on questioning, the formulation of hypotheses, testing of hypotheses and, above all, on communication between people.

Nuffield Chemistry[3] aimed to encourage students to be ‘scientific about a problem’ (Nuffield Foundation 1966b). This was based largely on the project team’s perception of what ‘being scientific’ means to a scientist: the application and the personal commitment involved, the importance of the disciplined guess or ‘hunch’ as well as logical argument, the feeling of exploration and the readiness to make apparently unwarranted jumps whilst knowing how to check their validity.

The Nuffield Chemistry project produced an extensive series of Background Books for students which were intended to amplify and extend work done in class and to stimulate the interest of pupils in wider aspects of their study. Many of these short readers were historical featuring the work of famous scientists from the early nineteenth century to the mid-twentieth century. *The Way of Discovery*, one of the Stage III Background Books, began with a short statement about the origins of scientific knowledge as an introduction to a series of personal accounts based on interviews with 14 Nobel Prize-winning scientists.

However, there were no explicit learning outcomes about the nature of science. Understanding of the methods of scientific enquiry was treated as a tacit aspect of science learning (Millar 1997). There was no significant credit in the O-level examinations for this kind of learning.

Nuffield Physics,[4] like the other Nuffield courses, was committed to presenting the subject as a connected fabric of knowledge with a focus on key concepts (Nuffield Foundation 1966c). Under the influence of Eric Rogers, the project team wanted students to acquire the feeling of doing science, of being a scientist – ‘a scientist for the day’. As with the other courses, the teaching approach was based on a guided introduction to physics concepts related to hands-on practical work by learners. Even so, the history of physics was of particular importance in the fifth year of the course which traced the development of theories about the solar system from ancient Greek models to the grand Newtonian synthesis (Nuffield Foundation 1966d). However, as the Teachers’ Guide to Year V shows, the main focus of the teaching was on Newton’s laws of motion, circular motion and other related concepts.

Paul Stevens was one teacher who explored the contradictions between the ‘discovery learning’ encouraged by the Nuffield courses and the ultimate aim of teachers to induct their students into the accepted scientific explanations (Stevens 1978). He argued that there was a logical conflict between ‘discovering’ and ‘learning’ which could produce some undesirable psychological results. In his view the fragmentary Nuffield philosophy, in so far as it could be abstracted from the publications, was bound to influence teachers into misleading students about the nature of science.

Jonathan Osborne (2007) has also pointed out that Eric Rogers' vision of what it means to be a 'scientist for a day' was a very narrow one based predominantly on the exact sciences of physics and chemistry and a hypothetico-deductive methodology. Osborne also gives examples to show why it was wrong to think that the learning of science and the doing of science could be regarded as one and the same thing. Whilst the practice of science is the search for answers concerning unanswered questions that we have about the material world, the task of science education is different. Its role is to construct in the young student a deep understanding of a body of existing knowledge.

63.3 Integrated and Process Science

Another course devised for more able learners was the Schools Council Integrated Science Project (SCISP),[5] known as *Patterns*, which was designed as a 3-year course to O-level for 13–16-year-olds (Schools Council 1973). This was developed in the late 1960 and early 1970s with the aim of providing a broad and balanced science curriculum in about a fifth of the available curriculum time in schools. That is the time that was typically allocated to two of the three traditional science subjects.

The rationale for integration was that all scientists use the same general approach to their work: the 'art' of science that is common to all areas of the subject. In *Patterns* this 'art' was expressed in terms of 'pattern-seeking' and 'problem-solving'. Throughout the scheme, students were expected to search for generalisations which could be expressed as patterns. These patterns were then used to solve scientific problems.

The American psychologist Robert Gagné was a major influence on SCISP. His thinking shaped the pedagogy and also helped to justify the notion that the content of science did not matter. His view was that knowledge was evolving so rapidly that anything learnt today might be redundant tomorrow. The enduring features of science were its processes. Hence, what young scientists needed to learn were processes: measurement, observation, hypothesis generation, experimental design and so on (Adey 2001).

The SCISP project team pointed out that they were not presenting their approach as *the* 'scientific method'. However, in later projects such as *Warwick Process Science* (Screen 1987) and *Science in Process* (Inner London Education Authority 1987), there was even more emphasis on a common set of scientific processes such as observing, classifying, inferring, investigating, predicting, hypothesising and evaluating. In these courses there was a clear implication that these activities in school reflected the ways in which scientists work across a wide range of scientific disciplines.

Unlike SCISP, these later integrated and process-based science courses, published in the 1980s, were planned in order to offer something to students across the ability

---

[5] All the original Schools Council Integrated Science Project publications are available from the National STEM Centre eLibrary at http://stem.org.uk/cxug

spectrum in the expectation that the most able students would find challenge in working at processes and meet the demand for problem-solving with sophistication, whilst the less able students would find the work stimulating without experiencing failure and consequent disillusionment with science.

However, this particular view about the nature of science was later criticised by Paul Black (1986) in his presidential address to the Association for Science Education. He warned against the temptation for curriculum planners to invent their own theories of knowledge, of philosophy and of culture. He pointed out that the philosophy of biology has its own agenda, distinct from the philosophy of physics, dealing, for example, with questions of reductionism, the general problem of teleology, the notion of organicism and whether or not biology can claim to have its own distinctive laws. One of the principles for curriculum design in science, he suggested, is that teaching should acknowledge the diversity and spectrum of differences across the sciences.

Robin Millar and Rosalind Driver (1987) in an article called *Beyond Process* presented a detailed critique of the assumptions that were being used at the time, more or less implicitly, as a basis for the case for 'process science' and which were, in their view, in danger of luring science educators along a misguided path. In examining the 'processes of science' from the perspective of the philosophy of science, they argued that there is no evidence to support the view that there is a unique and distinctive method of science based on a set of generalisable processes.

63.4 Science, Technology and Society (STS) Courses

In the mid-1970s science teachers recognised a fresh challenge. Despite the development work of the previous decade, young people were not opting for science. The term 'flight from science' had become current since the publication of the 1968 Dainton Report which had shown that the number of students studying science in the upper secondary school was declining. Some of the teachers who had taken leading roles in Nuffield projects, including John Lewis, a physics teacher in a selective independent school, surmised that they had enjoyed themselves too much investigating the intellectual niceties of theoretical science, when they should have been more concerned with the interplay between science and society (Lewis 1987). However, at the time, most science teachers felt ill-equipped to present a broader view.

In response the Association for Science Education gave support to two curriculum development projects in England that produced Science, Technology and Society (STS) courses for school students (Aikenhead 1994; Hunt 1994). One of the STS course was 'Science in Society', which was led by John Lewis (1981).[6] This course was strongly influenced by the 'Club of Rome' report on the limits to global

---

[6] The *Science in Society* Teacher's Guide and Readers are available from the National STEM Centre eLibrary at http://stem.org.uk/cx9s

growth (Meadows 1972). The other was 'SISCON in Schools'[7] headed by Joan Solomon (1983), then a teacher in a state school. Her team drew inspiration from SISCON – Science In a Social CONtext – that had been inaugurated in 1971 for students in universities and polytechnics.

Both these courses were able to innovate and experiment with new themes because they were studied by post-16 students in the slot in the timetable for general studies intended to broaden the curriculum for those taking two or three specialised academic A-level courses. Teachers had a great deal of freedom in their choice of courses to run as part of general studies because they did not count for much outside schools.

The place of the science in STS courses was a matter for debate (Solomon 1988). Research had suggested that students were often resistant to accepting and applying scientific knowledge in the context of social issues because they had difficulties in reconciling the uncertainties of the issues with what they perceived as science's claims to 'truth' (Aikenhead 1987; Fleming 1986). This led to the view that in STS courses it was important that students should learn something about the nature of scientific theories. Proponents of STS courses argued that students needed to appreciate the role of imagination in the development of theories, the importance of modelling and the relationships between data and explanations. In addition it was suggested that students needed to appreciate something about the provisional and uncertain nature of scientific theories.

Science in Society Reader J called *The Nature of Science* featured essays by a range of authors. One essay contrasted Baconian induction with the views of Karl Popper on the scientific method. Another essay in the reader outlined the ideas of Thomas Kuhn on how scientific ideas develop. Other essays dealt with the role of imagination in science and with the interfaces between science and religion. Reader K *Science and Social Development* opened with an essay by Sir Desmond Lee included a discussion of the extent to which Greek speculation about the nature of the physical world could be regarded as scientific in the modern sense of the term.

The nature of science was explored in the SISCON reader called *How can we be sure?* which included chapters about observations and generalisations and about the birth of scientific theories. This reader also included a historical section about changes in scientific explanations such as changes in theories about light and about burning.

In his review of the rationale for STS courses, John Ziman (1994) discussed the diversity of approaches to STS. In his view, the fundamental purposes of STS education were genuinely and properly diverse and incoherent. He identified and commented on seven different approaches drawn from STS initiatives around the world including the historical approach and the philosophical approach both of which had featured to a limited extent in the English STS programmes.

Commenting on the historical approach, Ziman noted that the history of science had long been regarded as the most natural medium for humanising science education

but that this was not without serious disadvantages. One disadvantage was that since the actual history of science is peculiarly deep, subtle and complicated, for most students the history of science is just too academic and remote. This leads to a related disadvantage, namely, that elementary accounts of the history of science in school end up as historically inaccurate celebrations of scientific progress which attribute heroic qualities to a few exceptional individuals. This echoes Stephen Brush's concern that the history of science in schools all too often leads to fictionalised idealizations and conveys a view of history that implies that science is a steady and cumulative progression towards the pinnacle of modern achievements (Brush 1974). Despite these warnings, teachers and curriculum developers continued to feature historical case studies whilst generally ignoring the new historical interpretations.

The two pioneering post-16 STS courses were only adopted by a small minority of students for study after the end of their compulsory period of education. Nevertheless, they proved influential because the resources they published helped to introduce teachers to ways of linking their science teaching to the world outside school or college. The projects also featured new teaching approaches for engaging the interest of their students in issues related to the nature of science and its applications (Lewis 1987). Curriculum developers who had been involved in these projects were soon taking leading roles in the Science, Technology in Society (SATIS) projects. These were very much more widely adopted and later were major influences on the first version of the national curriculum.

63.5 The SATIS Projects

Michael Young (1971), when discussing the stratified and specialised nature of the traditional school curriculum, contrasted the closed, narrow, high-status curriculum suited to potential future science specialist (such as the Nuffield O-level schemes) with open, broad, low-status programmes for the rest. He argued that under this regime it was inescapable that most of those who succeeded in school science would be systematically denied the opportunity to grasp science as an integral and unavoidable part of social life, whilst the rest, the failures, would leave school to become members of a scientifically illiterate public.

By the early 1980s this view was becoming more widely shared as shown by the first UK government statement about the science curriculum which made the case for broader, less specialised science programmes in school (Department of Education and Science 1985). This statement defended the proposed changes by claiming that science courses could challenge able students not by the task of accumulating greater stores of scientific knowledge but by the application of scientific principles to the real world, by the opportunity to investigate and solve problems and by the necessity of bringing scientific method to bear on assignments where the answer cannot be predicted in advance.

In line with the official guidance, significant changes in science education took place. In many schools, the option to study one, two or three of the separate sciences was replaced by compulsory science courses occupying 20 % of curriculum time from the age of 14 to the age of 16. These programmes of ‘balanced science’ were variously integrated, co-ordinated or combined, but, like SCISP, they had the common aim of making sure that all young people continued to study elements of biology, chemistry and physics as well as other aspects of science such as earth science and astronomy throughout their secondary education. This could be a challenge for teachers who were no longer working with students who had chosen to study their specialist subject.

Also at this time, the old system of public examinations for 16-year-olds (based on O-levels and the CSE) was being replaced by the new General Certificate of Secondary Education (GCSE) for all young people in schools. For the first time national criteria were introduced to control the new GCSE syllabuses. Amongst other things, the criteria for science required that not less than 15 % of the assessment of science should be related to the technological applications of the subject with their social, economic and environmental implications.

In this context, the Association for Science Education (ASE) launched the first Science and Technology in Society (SATIS) project in 1984 with the support of a charitable trust and a range of industrial companies (Hunt 1988). John Holman was appointed as director having played a key role in the *Science in Society* project. The small team recruited to the project was made up mainly of teachers. Despite the imposition of the new GSCE criteria, teachers still had the expectation that they could shape the interpretation of the new courses in schools.

The team decided to develop a bank of short resource units. Each unit related to a major topic in science syllabuses whilst exploring important social and technological applications and issues. Almost all of the units were written by a larger number of contributing teachers, often in co-operation with experts from industry, higher education, agriculture or the public services. In this way the project brought new stories, case studies and examples into science education. Between 1986 and 1991 the project published 120 units each requiring a lesson or two of class time.[8]

The SATIS units were not developed according to a predetermined plan, but, in response to the coverage of GCSE syllabuses and examinations, they clustered into themes such as materials, energy resources, the environment, health and ethical issues. None of the units in this project dealt with the nature of science because this did not feature in the GCSE courses at that time. However, there were some historical units thanks to contributions from the historian, Anthony Travis (1993), a former science teacher, whose research was focussed on the origins of the chemical industry, notably the dyestuffs industry.

As a result, the project published units about the work of Fritz Haber (number 207), the discovery of Perkin’s mauve (number 510), the quest for medical ‘magic bullets’ by Paul Ehrlich (number 805) and the ingenious contributions of Carl Bosch to the commercialisation the Haber process (number 810). These units did not

---

[8] All the SATIS units together with a General Guide for Teachers and an update of the first 100 units are available from the eLibrary of the National STEM Centre (Accessed in March 2012 from http://stem.org.uk/cx9n)

present a particular view of the nature of science but touched on the human side of scientific discovery and the social implications of technological changes.

The units were presented in the form of short teachers' notes with student worksheets which schools were free to copy. ASE was able to publish the units cheaply at just the right time with the result that they were very widely adopted. This form of publishing became very popular in the UK and other projects adopted a similar pattern. Between 1995 and 1999, for example, ASE produced a series of SATIS-style units to celebrate key centenaries in the history of science.[9]

Following the success of the first SATIS project, the ASE decided to extend the work to older students. The new project, SATIS 16–19, was similar to SATIS in many ways: it was funded on a similar basis, teachers determined the policy and did the writing, and the intention was to produce a bank of varied resource materials to enrich existing courses. The project team set out to support both the general education of all students as well as to provide resources to supplement specialist science programmes.

In addition to the 100 SATIS 16–19 units[10] published between 1990 and 1992, the project also published three readers written by Joan Solomon which were designed to provide a rationale for planning the STS component in programmes of general education. The first of the readers, *What is Science?*, encouraged students to reflect on the nature of scientific theories and to consider where imaginative scientific theories come from. Examples from the history of science were included to show how scientific theories change and to explore the interplay between science and society. The sections of this reader were cross-referenced to related SATIS 16–19 units, allowing students to examine selected topics in more depth. The related units included *The retrial of Galileo* (unit 1), *Two games and the nature of science* (unit 26), *Patterns in the sky* (unit 51), *Why do we grow old?* (unit 61) and *Science and religion – friends or foes?* (unit 77).

An important aspect of these two SATIS projects was the way that they helped to legitimise activities which had not previously been common in science lessons. The units provided teachers with models for lessons involving discussion techniques, role plays, analytical reading, data analysis and problem-solving. These approaches to teaching and learning were essential in broadening school science to encompass historical topics and studies of the nature of science.

Following their experience with STS and SATIS projects, John Holman and Joan Solomon went on to make significant contributions to the development of the first national curriculum for England and Wales. John Holman was a member of the core working group that drafted the new curriculum, and Joan Solomon acted as adviser for the development of AT17.

63.6 The Nature of Science in the National Curriculum

The first version of the national curriculum for England and Wales was introduced in 1989. It was divided into 17 strands, called attainment targets (Department of Education and Science 1989). Two of these attainment targets conveyed generic messages about science: AT1 Exploration of Science and AT17 The Nature of Science. Jim Donnelly (2001) has discussed the tensions between AT1 which drew on a broadly empiricist and inductivist tradition in science education and AT17 which was strongly influenced by STS thinking with its emphasis on the social and cultural dimensions of science.

Professor Jeff Thompson was chair of the working group that drafted the science curriculum. He had been active in the Association for Science Education and 10 years earlier had chaired the ASE group that wrote the consultative document *Alternatives for Science Education* (ASE 1979). This report had aimed to anticipate possible developments in the structure of the science curriculum by describing three possible curriculum models. All three models included aspects of the history and philosophy of science. Thus the chair and several members of the national curriculum group had an interest in introducing AT17 despite the challenge that this would present to many science teachers.

Stephen Pumfrey's critique (1991) of this first version of the national curriculum concentrated on AT17. He pointed out that a curious feature of this attainment target was that it nowhere gave an explicit answer to the question ‘What is the nature of science?’ He suggested that these nine ideas were the key ingredients of what the answer implied by AT17 appeared to be:

1. Meaningful observation is not possible without a pre-existing expectation.
2. Nature does not yield evidence simple enough to allow one unambiguous interpretation.
3. Scientific theories are not inductions, but hypotheses which go imaginatively and necessarily beyond observations.
4. Scientific theories cannot be proved.
5. Scientific knowledge is not static and convergent, but changing and open-ended.
6. Shared training is an essential component of scientific agreement.
7. Scientific reasoning is not itself compelling without appeal to social, moral, spiritual and cultural resources.
8. Scientists do not draw incontestable deductions, but make complex expert judgements.
9. Disagreement is always possible.

In exploring these ideas, students were expected to learn about stories from the history of science. Pumfrey highlighted tensions implicit within AT17 which, on the one hand, recognised that there have been different values and forms of natural knowledge in different times and contexts whilst, on the other hand, expecting historical case studies to illustrate the norms of scientific practice today.

Pumfrey illustrated his arguments with reference to teaching resources developed under the leadership of Joan Solomon. She had not only contributed to the formulation of AT17 but also had been one of the people who led initiatives to support its implementation in schools. Her first publications were short readers telling stories about developments in the history of science written for 11–14-year-olds to illustrate aspects of the nature of science.[11] Next she worked with groups of teachers in schools to devise a varied collection of teaching and learning activities covering all the aspects of AT17. These lesson ideas were published in two volumes called *Exploring the Nature of Science*: one for 11–14-year-olds (Key Stage 3) (Solomon 1991) and one for 14–16-year-olds (Key Stage 4)[12] (Solomon undated).

Many of the activities in *Exploring the Nature of Science* were based on historical case studies. The introduction to the Key Stage 3 book shows that the authors were sensitive to the tensions identified by Stephen Pumfrey by stating that:

> The greatest difficulty with teaching history is understanding just what scientists in another age meant by the terms they used – like ‘atoms’, ‘heat’ or even ‘…made of water’. In none of these cases were the meanings exactly as they are today. The subtlety of historical research lies in trying to understand the thinking of scholars who were influenced by philosophies that few of us have even encountered. Inevitably we are forced to simplify, both through lack of time, and because our basic intention is not to lecture on the history of science, but to teach children about the nature of science (Solomon 1991, Introduction – *no page numbers*).

The Nuffield-Chelsea Curriculum Trust[13] had also responded to AT17 with a publication called *Investigating the Nature of Science.*[14] The file was devised by a team from King’s College London. It aimed to support teaching of all aspects of AT17 to 11- to 16-year-olds. The resource provided detailed lesson ideas covering 12 topics explored with the help of a variety of methods that included discussion, role-play, experimental work, models and guided reading (Honey 1990).

This file contained an introduction to explain the rationale of AT17. This began with a discussion of the reasons for covering the nature of science in a science course. The authors pointed out that a view of the nature of science is implicit in any science course and suggested that it is desirable to articulate and clarify what this view is so that, for example, students understand better the relationships between experiments and theory.

The introduction to the file went on to explain how misconceptions about science can arise in the minds of learners both from messages in the media and from the

[13] From the late 1970s to the early 1990s, the Nuffield Foundation’s support for curriculum development in science, maths and technology education was the responsibility of the Nuffield-Chelsea Curriculum Trust based at Chelsea College.

[14] *Investigating the Nature of Science* is available from the National STEM Centre eLibrary at http://stem.org.uk/rx3a7

experience of school science. Finally the authors reviewed some differing views about the nature of science before suggesting ways of making the history and philosophy of science part of the school curriculum.

63.7 The Short Life of AT17

The first version of the science national curriculum was so detailed and complex that a revision began very soon after it was launched in schools. Given the many demands made by the new curriculum, and the lack of expertise and limited resources for teaching AT17, there was little opposition when, in 1991, this attainment target was merged with the first attainment target (AT1) that covered investigative practical science (Department of Education and Science 1991).

It is not surprising that few teachers regretted the passing of AT17 in view of the argument put forward by Martin Monk and Jonathan Osborne (1997). They suggest that the failure of the history of science to contribute to the mainstream of science teaching arises because teachers have no confidence that a historical context adds anything to their students' knowledge and skills. Within the classroom, teachers' dominant concerns are the development of the student's knowledge and understanding of the content of science; that is with 'what we know' rather than 'how we know'. Many teachers also lack the requisite knowledge of either the history of science or the nature of science to explore any of these issues appropriately. Teachers are heavily influenced by the demands of external assessments. The early national curriculum tests did little to support the teaching of AT17.

63.8 Rethinking the Purposes of Science Education: Beyond 2000

The first major review of the national curriculum as a whole was carried out by Sir Ron Dearing, a former senior civil servant who had recently been chief executive of the Post Office Ltd. His report (Dearing 1993), published in 1993, argued that the curriculum had become an unwieldy structure which was virtually impossible to implement. As a result a further revision was carried out to cut down the content and to eliminate overlap between subjects. Coverage of the nature of science was reduced in emphasis in the resulting 1995 version of the science curriculum (Department of Education and Science 1995). The consequence was that there was little or no attention given to teaching about the history of science and the nature of science by most teachers in pre-16 courses for the next 10 years or so.

Following the Dearing review, the government announced a 5-year moratorium on curriculum change. This provided an opportunity for reflection which was taken up by Rosalind Driver and Jonathan Osborne of King's College, London. A grant from the Nuffield Foundation provided the support for a seminar series to 'consider and review the form of science education required to prepare young people for life in our society in the next century'.

The series of six invitation seminars were held between 1997 and 1998. In addition there were two open seminars to widen the discussion to include teachers and others with an interest in the future of science education. The *Beyond 2000* report (Millar and Osborne 1998) from the seminar series made the case for finding better ways to meet the two main purposes of science education for 14–16-year-olds:

- To develop the 'scientific literacy' of all students in preparation for adult and working life
- To provide the foundations for more advanced courses in science

The report proposed that the same curriculum could not serve both purposes, especially in the final 2 years of compulsory education. It recommended that the structure of the science curriculum should differentiate more explicitly between those elements designed to enhance 'scientific literacy', and those designed as the early stages of a specialist training in science, so that the requirement for the latter would not distort the former.

The report outlined the aims and nature of a 'scientific literacy' course. Alongside the aim of introducing young people to the major 'explanatory stories' of science about life and living things, matter, the Universe and the made world, a key aim of such a course was that it should give young people an understanding of how scientific inquiry is conducted. The report summarised the rationale for teaching 'about science' in this paragraph:

> In order to understand the major 'explanatory stories' of science, and to use this understanding in interpreting everyday decisions and media reports, young people also require an understanding of the scientific approach to inquiry. Only then can they appreciate both the power, and the limitations, of different kinds of scientific knowledge claims. They also need to be aware of the difficulties of obtaining reliable and valid data. Science issues are often about the presence or absence of links and correlations between factors and variables, often of a statistical and probabilistic kind, rather than directly causal – so young people need an understanding of these ideas, and practice in reasoning about such situations. Often the plausibility of a claimed link depends on seeing a mechanism which might be responsible – and here again an understanding of the major 'explanatory stories' of science is needed. Finally, young people need some understanding of the social processes internal to science itself, which are used to test and scrutinise knowledge claims before they can become widely accepted – in order to appreciate their importance, but also to recognise the ways in which external social factors can influence them (Millar and Osborne 1998, pp. 19–20).

The *Beyond 2000* report set out in some detail the ideas-about-science that it recommended should feature in a scientific literacy course. The authors of the report warned that these ideas-about-science represented a significant expansion of the range and depth of treatment that such issues currently demanded in the existing curriculum. As a result, they pointed out that any development based on the recommendations needed to be undertaken in collaboration with science teachers so that their introduction could be a managed process and not a sudden, and possibly unwelcome, event.

63.9 Science for Public Understanding

Following his review of the national curriculum, Sir Ron Dearing was asked to review post-16 qualifications in England, Wales and Northern Ireland including A-levels. Included in his report was a recommendation for a new Advanced Subsidiary (AS) exam to be taken after 1 year post-16 to encourage students to broaden their studies by studying up to five subjects in place of the traditional three (Department for Education and Employment 1996). This would allow students to begin their post-16 programme with, say, five AS-levels – and then choose three of these to continue to A-level. They could obtain an AS-level qualification in the two that they took for just 1 year. It was suggested that the two additional AS courses taken might complement or contrast with the main areas of the students' specialist interests.

This change to the post-16 academic curriculum threw up an opportunity to reassess existing STS courses and make a fresh start. As before, there was considerable freedom allowed for the style and content of courses intended to broaden the curriculum. These courses were not subject to the detailed national guidelines that applied to mainstream advanced courses. One of the examining boards[15] invited Robin Millar to take the lead in developing a new course (Millar 2000). He had published an article outlining his thinking which set out ideas that he was also contributing as co-author of the report from the *Beyond 2000* seminars (Millar 1996).

In this way, the AS *Science for Public Understanding* course became a test-bed for trying out a model of a scientific literacy course as described in the *Beyond 2000* report. The syllabus[16] for this new course gave the same weighting to ideas-about-science as it did to explanatory theories (Millar and Hunt 2002). The course was presented as a series of topics which provided the contexts for teaching about science explanations and about the nature of science. The topics were divided equally between issues in the life sciences and issues in the physical sciences.[17]

Some of the topics were treated historically. One example was 'Understanding health and disease' that, in part, used the work of people such as Snow, Semmelweis and Pasteur to explore ideas-about-science including the distinction between correlation and cause, the origins of scientific explanations and how the scientific community resolves the conflicts between competing theories.[18] Other topics treated

---

[15] The invitation came from the Northern Examinations and Assessment Board (NEAB) which later merged with other examining bodies to form the awarding organisation that is now called AQA.

[16] Over the period covered by this chapter the older term 'syllabus' has been replaced by the term 'specifications'. Specifications are more explicit about aims, content, assessment model and grade criteria.

[17] From 2007, *Science for Public Understanding* became a full A-level subject with the name *Science in Society*. The AS specification (syllabus) for *Science in Society* is very much the same as its precursor and can be downloaded from the AQA website together with past examination papers (accessed in March 2012 from http://www.aqa.org.uk/qualifications/a-level/science/science-in-society/science-in-society-key-materials)

[18] For more details of the approach, see the revised version of the AS course textbook (Hunt 2008).

from a historical perspective were ‘Understanding who we are’ which included study of the theory of evolution and its origins and ‘Understanding where we are’ which traced the development of theories of the solar system and the Universe. The other topics in the course also introduced and applied ideas-about-science when dealing with contemporary issues, including ethical issues. The textbook included an outline of some ethical frameworks to help students discuss the issues.

The teaching approach adopted for the course drew on the experience of earlier STS courses. *Science for Public Understanding* aimed to help students understand more about the nature of science and to provide them with the skills needed to participate as citizens in debates on topical science. The course therefore expected students to develop their abilities across a wider range of concepts and skills than in most traditional science classes.[19]

The timetable for introducing the new AS courses made it possible to pilot AS *Science for Public Understanding*. The first cohorts of students took pilot examinations in June 1999 and June 2000. By this time it was becoming clear that there would be an opportunity to test out the recommendations of the *Beyond 2000* report in a set of novel GCSE courses supported by a large-scale curriculum development project that came to be called *Twenty First Century Science*. With this in mind, the Nuffield Foundation commissioned a team from King’s College London to make a study of the teaching and learning of science explanations and the ideas-about-science in *Science for Public Understanding*.

The research was carried out between 2001 and 2002. The findings were published in a report called *Breaking the mould?* (Osborne et al. 2002a). The data gathered by the research team suggested that the course had been successful in achieving its first aim: to sustain and develop students’ enjoyment of, and interest in, science. The overwhelming majority of students said that the course was both enjoyable and interesting. Furthermore, the *Science for Public Understanding* course had managed to attract students who would not otherwise have studied science post-16. It was notable that nearly 60 % of all the students were female, which the researchers suggested was a significant achievement for a course where 50 % of the content was physical science.

However, the report showed that the new course made demands on teachers’ pedagogic techniques such as the skill to run and organise effective discussions that engage all students in thinking critically about socioscientific issues. The researchers pointed out that students need to be explicitly taught, not only how to evaluate media reports about science critically but also how to construct effective arguments which are reliant on evidence rather than personal or group opinion. The report stated that the available guidance on teaching methods was inadequate.[20]

The research demonstrated that changing the culture that forms and moulds teachers is much harder than simply changing the curriculum. To bring about changes requires

---

[19] Schemes of work and lesson activities originally devised for AS *Science for Public Understanding* are available as revised and updated versions from the AS section of the *Science in Society* website: http://www.nuffieldfoundation.org/science-society (accessed March 2012).

[20] The *Science for Public Understanding* (now *Science in Society*) website was developed in response to this criticism (http://www.nuffieldfoundation.org/science-society)

considerable support, effort and time. The researchers concluded that the course had begun that process and planted the seeds of a different way to teach and engage students but that enabling it to take root would require continued endeavour.

Within a year of the launch of the new AS courses, as part of Curriculum 2000, it became clear that, despite expectations, most students would opt for four rather than five AS courses. As a result the interest in 1-year AS courses, such as *Science for Public Understanding*, was less than expected, but the numbers of candidates for the exams were significantly larger than had been the case for its STS predecessors at this level.

63.10 Evidence-Based Practice in Science Education (EPSE)

Between January 2000 and June 2003, a research network, funded by the Economic and Social Research Council (ESRC), carried out four interrelated projects to improve the interface between science education researchers and teachers. The aim of the programme was to develop and evaluate several examples of evidence-based practice in science education.

The lead researchers had all been involved in the *Beyond 2000* seminar series. One of the projects set out to examine the curriculum implications of the recommendation that the aim of compulsory science education should be to develop 'scientific literacy' by providing a basic philosophical understanding of the nature of science, the function and role of data in scientific argument and how the scientific community functions (Osborne et al. 2006). This project was begun in response to the notion that a shift towards science education for citizenship implied a broadening in the range of stakeholders with a legitimate interest in determining the goals of the school science curriculum.

Accepting that the nature of science is seen by contemporary scholars as a contested domain, and given the lack of empirical evidence of consensus, the research team decided to try to determine empirically the extent of agreement amongst a group of experts about those aspects of the nature of science that should be an essential feature of the school science curriculum. The method chosen for eliciting the view of the expert community was a Delphi study (Osborne et al. 2003). In this way the researchers sought to establish consensus amongst a group made up of five representative individuals from each of these groups: leading scientists, historians, philosophers and sociologists of science, science educators, those involved in science communication and primary and secondary teachers of science.

Using three rounds of linked questionnaires, where the responses were sifted and successively commented on, the researchers determined the level of agreement amongst the experts about which ideas-about-science were so important that they should be included in school science. At the end they arrived at a strong consensus about nine common themes that are summarised in Table 63.1 (Osborne et al. 2002b).

Table 63.1 Findings of a Delphi study summarising the views of experts about those aspects of the nature of science that should be an essential feature of the school science curriculum (Osborne et al. 2002b, p. 30)

Nature of scientific knowledge

Science and certainty

Students should appreciate why much scientific knowledge, particularly that taught in school science, is well established and beyond reasonable doubt and why other scientific knowledge is more open to legitimate doubt. It should be explained that current scientific knowledge is the best we have but may be subject to change in the future, given new evidence or new interpretations of old evidence

Historical development of scientific knowledge

Students should be taught some of the historical background to the development of scientific knowledge

Methods of science

Scientific methods and critical testing

Students should be taught that science uses the experimental method to test ideas, and, in particular, about certain basic techniques such as the use of controls. It should be made clear that the outcome of a single experiment is rarely sufficient to establish a knowledge claim

Analysis and interpretation of data

Students should be taught that the practice of science involves skilful analysis and interpretation of data. Scientific knowledge claims do not emerge simply from the data but through a process of interpretation and theory building that can require sophisticated skills. It is possible for scientists legitimately to come to different interpretations of the same data and, therefore, to disagree

Hypothesis and prediction

Students should be taught that scientists develop hypotheses and predictions about natural phenomena. This process is essential to the development of new knowledge claims

Diversity of scientific thinking

Students should be taught that science uses a range of methods and approaches and that there is no one scientific method or approach

Creativity

Students should appreciate that science is an activity that involves creativity and imagination as much as many other human activities and that some scientific ideas are enormous intellectual achievements. Scientists, as much as any other profession, are passionate and involved humans whose work relies on inspiration and imagination

Science and questioning

Students should be taught that an important aspect of the work of a scientist is the continual and cyclical process of asking questions and seeking answers, which then leads to new questions. This process leads to the emergence of new scientific theories and techniques which are then tested empirically

Institutions and social practices in science

Co-operation and collaboration in development of scientific knowledge

Students should be taught that scientific work is a communal and competitive activity. Whilst individuals may make significant contributions, scientific work is often carried out in groups, frequently of a multidisciplinary and international nature. New knowledge claims are generally shared and, to be accepted by the community, must survive a process of critical peer review

63.11 School Science and the Changing World of the Twenty-First Century

A new version of the whole national curriculum for England was published in 2000, but there was little change to the science curriculum. The main change was a modification of the section about scientific enquiry to incorporate some new content covering ‘ideas and evidence’.

Influenced by the *Beyond 2000* report, the government asked the Qualifications and Curriculum Authority (QCA) to begin a project which it called ‘Keeping School Science in Step with the Changing World of the twenty-first Century’. The QCA was responsible for curriculum in England at that time. By now it had become very difficult for school teachers to take the initiative and shape the core curriculum through their active membership of the Association for Science Education. Politicians and regulators were in charge.

QCA commissioned researchers to investigate three issues: what students would need to become scientifically literate citizens, what should constitute a curriculum to meet those needs and how students’ learning in a new and different science curriculum could be assessed (QCA 2006).

The first study involved consulting groups with an interest in school science education about the features of the proposed curriculum. The consultation was carried out by a group of researchers from the Centre for Studies in Science and Mathematics Education, University of Leeds (Leach 2002). Secondary science teachers in focus groups were presented with an outline of a curriculum, broadly in line with the thinking in the *Beyond 200*0 report, with these features:

- It views pupils as potential users and consumers of science, rather than as potential producers of scientific knowledge.
- It aims to give pupils a sense of the cultural significance of science.
- It covers less of the traditional conceptual content of science, allowing time to cover key areas in significantly more depth.
- It gives more attention to the ways in which science works, emphasising ‘how we know what we know’.
- It introduces scientific disciplines that predict risk, such as epidemiology, and reduces the amount of time spent on the ‘traditional’ school science disciplines of physics, chemistry and biology.

The findings from this study suggested that secondary science teachers were generally dissatisfied with the existing curriculum and supportive of change; however, they did not share a common vision of what a science curriculum for all students might look like. The researchers concluded that any future attempts to change the focus of the science curriculum would have to take seriously the need for such a shared vision to emerge within the science teaching profession if the changes were to be successful. Consulting more widely, the study identified many ‘critical voices’ in relation to the meaning and feasibility of the goals of scientific literacy.

The second study was carried out by researchers from King’s College London and the University of Southampton (Osborne and Ratcliffe 2002). The aim was to explore appropriate methods of assessment for a new curriculum featuring ideas and evidence, in a curriculum intended to develop understanding of the nature and limitations of scientific endeavour, through historical and contemporary contexts. The challenge was to find assessment tasks which would encourage teachers to explore not only which scientific ideas are believed but why they are believed. The researchers were looking for assessment items covering the relationships between the claims, data and warrants for trust in scientific ideas.

The research team studied examples of assessment in this field from across the world. In their interim report the researchers stated that it was their general impression that, internationally, the assessment of the nature and processes of science was an underdeveloped field. They reported that they had found relatively few sources that had created a significant body of items for testing understanding of the nature of science, the analysis and interpretation of data and the processes of science. Nevertheless they were able to use their findings to assemble four written tests and four teacher-assessment tasks that were tried out in schools.

From the analysis of the test results, the research team concluded that reliable and valid items for testing pupils' understanding of the processes and practices of science in contemporary or historic contexts could be developed. The researchers argued that many of the items and the teacher-assessment tasks offered authentic contexts for assessment. However, they pointed out that teachers considered the amount of reading and the language level to be off-putting, but that such comments reflected a tension between what was currently being taught and the comparative 'novelty' of the content and emphases of the items being trialled. The researchers identified unresolved issues and areas in which further work was needed.

The third study was carried out by the University of York Science Education Group (UYSEG) in collaboration with the Association for Science Education and the Nuffield Curriculum Centre. The aim was to devise a curriculum model that would meet the two overarching purposes of science education identified in the *Beyond 2000* report: the development of scientific literacy for all and preparation for post-compulsory science study for some.

The curriculum model proposed that all students would complete a 'core' course (UYSEG 2001). This course would provide 'a broad, qualitative grasp of the major science explanations' and also include insights into the nature of science and its relation to social and ethical issues. In addition, most students would also opt for one of two additional science courses offering either traditional science content or a focus on the applications of science within everyday and work-related contexts (*Twenty First Century Science* project team 2003).

QCA acted on the recommendations of the third study and commissioned the OCR awarding organisation[21] to produce a suite of pilot GCSE qualifications to match the curriculum model. QCA used the findings of the second project to inform

---

[21] There are three awarding organisations in England responsible for GCSE and A-level specifications (syllabuses) and examinations. The three were formed by the merger of a number of previous examination boards. The three are AQA, Edexcel and OCR. Specifications and examinations have to conform with national criteria that were formerly produced by QCA but are now controlled by a regulator called Ofqual.

the national testing of science for younger pupils, but there was a lack of thorough development work to devise appropriate methods of assessment of ideas-about-science for GCSE courses. The recommendations of the first study were not followed up (Ryder and Banner 2011).

The University of York Science Education Group and the Nuffield Curriculum Centre set up *Twenty First Century Science* as a large-scale curriculum development project to provide the teaching resources and support needed by the schools taking part in the trials of the new GCSE courses commissioned by QCA and run by OCR[22] (Millar 2006). The project was funded by grants from three charitable foundations including the Nuffield Foundation whose trustees supported the recommendations of the *Beyond 2000* report.

Development of the resources began in 2002 in preparation for a pilot that ran in nearly 80 schools from 2003. QCA carried out early, small-scale evaluation studies of the pilot and concluded, well before the end of the pilot, that the findings were sufficiently positive to justify reworking the national curriculum and GCSE science criteria broadly in line with the model being trialled (QCA 2005). A larger-scale evaluation of the pilot was commissioned by the charitable trusts funding the development project, but the findings were published too late to influence the national developments (Burden et al. 2007).

63.12 A New National Curriculum Featuring ‘How Science Works’

Drawing on all the work done since 2000, the QCA introduced a new version of the national curriculum in 2004.[23] This was divided into two major strands: ‘knowledge and understanding’ and ‘how science works’. The curriculum model was a response to the notion that science education should not only communicate a body of knowledge but also convey an understanding of how that knowledge has been, and continues to be, developed. This required that the curriculum place greater emphasis on the nature of science and the way scientists and the scientific community as a whole operate.

There were four main sections of the ‘how science works’ strand (Toplis 2011):

- Data, evidence, theories and explanations
- Practical and inquiry skills
- Communication skills
- Applications and implications of science

---

[22] The latest version of the Twenty First Century Science GCSE Science specification can be downloaded from the OCR website at http://www.ocr.org.uk/qualifications/type/gcse_2011/tfcs/ (accessed November 2011).

[23] This version of the national curriculum for students aged 14–16 will probably continue to apply until 2014. It is available from the Department for Education website: http://www.education.gov.uk/schools/teachingandlearning/curriculum/secondary/b00198831/science/ks4/programme (accessed June 2012).

Table 63.2 How science works in AQA and OCR-A specifications

Concepts of evidence in AQA specifications (the thinking behind the doing)	Ideas-about-science in Twenty First Century Science
Observation as a stimulus to investigation	Data and their limitations
Designing an investigation	Correlation and cause
Making measurements	Developing explanations
Presenting data	The scientific community
Using data to draw conclusions	Risk
Societal aspects of scientific evidence	Making decisions about science and technology
Limitations of scientific evidence	

However, the national curriculum has never provided enough information to allow regulators to set a detailed framework for GCSE specifications. To give awarding organisations more specific guidance, the curriculum authorities produce GCSE subject criteria. The new criteria published for the 2004 curriculum offered considerable flexibility with the result that the awarding organisations came up with very different interpretations of ‘how science works’. Two sets of specifications were based on fully developed rationales derived from research and scholarship. These are compared in Table 63.2. Most of the 600,000 or so students that take GCSE Science each year follow one or other of these popular courses.

AQA[24] adopted a rationale for teaching about the methods of science based on the work of Gott and Roberts (2008) at Durham University.[25] This approach focussed on the procedural understanding and understanding of concepts of evidence that are needed to carry out and interpret science investigations.

The OCR Twenty First Century Science specifications[26] were updated from the pilot versions and used the rationale for teaching ideas about science that informed the *Beyond 2000* report based on the work of Robin Millar and his collaborators at the universities of York, King’s College London, Southampton and Leeds. The approach in the core science specification was designed to develop the scientific literacy of all young people. The thinking was that a course based on this rationale would help to develop the knowledge and understanding that are most useful in interpreting and evaluating the sorts of science-based information and claims that everyone encounters in their adult and working lives (Millar 2013).

---

63.13 Assessing 'How Science Works'

At that time there was no significant investment in developing appropriate methods of assessing 'how science works' in written examination papers. Bringing in this new emphasis to the curriculum made fully explicit ideas that had previously been implicit. There was no accumulated expertise in assessing the ideas, which meant that the examiners for all the awarding organisations had much to learn. Consequently, in the early years the assessments had unsatisfactory features as shown by a SCORE[27] (2009) report on GCSE examinations.

The problems with the assessment of 'how science works' were investigated in more detail by research commissioned by SCORE in 2010. The research team reported that they had found wide variation in the breadth and depth of the treatment in the different GCSE course specifications and examinations (Hunt 2010).

One clear conclusion was that the societal (STS) aspects of this area of the curriculum were being given very substantial, but rather trivial, emphasis compared with the treatment of ideas related to the methods of science and the nature of scientific explanations.

The consequence was that the assessment practices were not fit for purpose and so did not have the confidence and support of the community including teachers. Test items in written examinations failed to show that they assessed knowledge and understanding that every young person needs. As a result many people failed to appreciate that the teaching of 'how science works' could be based on rigorous concepts and challenging learning goals.

The findings of SCORE and others led to a further revision of GCSE specifications and assessments with the aim of bringing greater clarity and consistency to the assessment of ideas related to the methods and nature of science.

63.14 Argumentation and the IDEAS Project

The introduction of 'how science works' emphasises the importance of educating students about how we know and why we see science as a distinctive and valuable way of knowing. This means that students need to explore reasons why accepted theories have become established and why alternative ideas are thought to be wrong (Simon 2011).

Shirley Simon, with Jonathan Osborne and Sibel Erduran at King's College London decided to study the implications of teaching science based on the view that what lies at the heart of science is the commitment to evidence as the rational basis for argument and justification. The group worked with teachers in a research project

---

[27] SCORE is a partnership of organisations which aims to improve science education in UK schools and colleges. The organisations: Association for Science Education, Institute of Physics, Royal Society, Royal Society of Chemistry and the Society of Biology.

called *Enhancing the Quality of Argument in School Science* (Osborne et al. 2004a). Influenced by their findings, they then developed the publications of the IDEAS project (Osborne et al. 2004b).

The team produced the pack to support the professional development of teachers. They did so because they believed that, in presenting scientific ideas and their supporting evidence to school students, it was essential to consider the arguments for the scientific ideas and other competing theories. One reason for this was that the research evidence suggested that the opportunity to consider why the wrong idea is wrong is as important as understanding the justification for the scientific idea. A second reason was that engaging in argument provides students with a better insight into the nature of scientific enquiry and the work of scientists.

Activities in the pack explored what is meant by the term ‘argument’ in science and why it is a significant feature of science, bearing in mind that the everyday meaning of the word ‘argument’ is not the one that is being used in this context. Teachers were introduced to Ron Giere’s (1991) epistemological framework and asked to discuss its relevance to sciences ranging from cosmology and geology to biochemistry and physics.

The pack also introduced teachers to the ideas of the philosopher Stephen Toulmin (1958). Activities in the pack gave participants opportunities to use Toulmin’s model to analyse and construct scientific arguments. The arguments were mainly related to evidence and explanations. Debate about socioscientific issues was included but was not the main focus of the activities.

63.15 How Science Works in Post-16 Specialist A-Level Science Courses

Following the changes to the national curriculum, the QCA, added a section on ‘how science works’ to the national criteria for A-level sciences when they were revised for post-16, specialist science courses starting in 2008 (Ofqual republished annually). Section 63.7 of the criteria includes the requirement that science A-levels should enable students to appreciate the tentative nature of scientific knowledge, consider ethical issues in the treatment of humans, other organisms and the environment and appreciate the role of the scientific community in validating new knowledge and ensuring integrity.

A review of the new A-level specifications based on these criteria shows that the new section covering how science works has had a limited impact on most courses.[28] However, the Advancing Physics[29] specification is of particular interest because it has a coherent rationale for ‘how science works’ fully integrated into the course

---

[28] This was found, for example, during an unpublished review of specifications carried out by one of the authors for SCORE in 2012.

[29] Information about the course, the published resources and the assessment can be found on this website: http://www.advancingphysics.org/ (accessed in June 2012).

design, content, assessable learning outcomes and scheme of assessment. This rationale covers relatively few ideas but in greater depth and provides a distinctive justification for the inclusion of 'how science works' in advanced courses. Students who follow this course are, for example, assessed on their ability to:

- Identify and discuss ways in which interplay between experimental evidence and theoretical predictions have led to changes in scientific understanding of the physical world
- Use computers to create and manipulate simple models of physical systems and to evaluate the strengths and weaknesses of the use of computer models in analysis of physical systems
- Identify and describe the nature and use of mathematical models
- Identify and describe changes in established scientific views with time

Some other advanced courses take a context-led approach which provides opportunities to feature case studies in the history of science. One example is Salters-Advanced Chemistry,[30] which uses aspects of the history of chemistry to illustrate conceptual and technological developments in some of the topics. Storylines in the course with a strong historical dimension include 'The polymer revolution', 'What's in a medicine' and 'Colour by design'.

Another context-led approach is Salters-Nuffield Advanced Biology.[31] This is a course that introduces students to ethical principles that enable them to analyse and discuss biological issues (Reiss 2008). Students learn about four ethical frameworks: rights and duties, utilitarianism, autonomy and virtue ethics. Implicit in the approach, as Michael Reiss explains, is the notion that one can be confident about the validity and worth of an ethical argument if three criteria are met (Reiss 1999). First, if the arguments that lead to the particular conclusion are convincingly supported by reason. Secondly, if the arguments are conducted within a well-established ethical framework. Thirdly, if a reasonable degree of consensus exists about the validity of the conclusions, arising from a process of genuine debate.

63.16 Teaching About the Nature of Science at A-Level

Research and development work to explore post-16 students' understanding of aspects of 'how science works' has been limited. However, starting in 1999, a team at the University of Leeds carried out a small-scale project, called *Teaching about*

---

[30] Information about the course, the published resources and the assessment can be found on this website: http://www.york.ac.uk/org/seg/salters/chemistry/index.html (accessed in March 2012).

[31] Information about the course, the published resources and the assessment can be found on this website: http://www.nuffieldfoundation.org/salters-nuffield-advanced-biology (accessed in March 2012).

Science during which they designed teaching resources[32] to develop students' understandings about aspects of the nature of science in post-16 A-level science courses. They evaluated the impact of the resources and identified areas of knowledge and expertise that act as barriers to teachers in using the materials to promote student learning about the nature of science (Leach et al. 2003).

The focus of the project was on epistemological aspects of AS-/A-level syllabuses. The lessons were designed to address misconceptions which research had shown to be commonly held by students. Students have misconceptions about the nature of theoretical explanations in science. They tend to believe that theoretical models emerge directly from data and that all features of a theoretical model correspond directly to features in the real world. They often fail to recognise the conjectural and tentative nature of many scientific explanations and that scientific explanations are often expressed in terms of theoretical entities which are not 'there to be seen' in the data. Three lessons were designed to address these misconceptions: A *Electromagnetism,* B *Cell membranes* and C *Continental drift.*

Other misconceptions relate to the assessment of the quality of scientific data. Students tend to see examination of the quality of scientific evidence as simply a matter of making a judgement about whether the scientists involved had made any mistakes. They often fail to recognise the inherent uncertainty of measurements and have little idea of how scientists deal with this uncertainty. Few students use ideas about the validity and repeatability of evidence in evaluating its quality or recognise the significance of examining the spread of a set of data. Lesson D *Chemical data* and lesson E *Mobile phones* were designed to address these misconceptions.

A third set of misconceptions relate to the purposes of scientific investigations. Students tend to see scientific investigation as a process of careful description. For such students collecting a 'good' set of data is the end of the data interpretation process. They often fail to recognise that many investigations involve the testing of ideas. The need to interpret the data in terms of scientific ideas is not recognised. Lesson F *Purposes of Science* was designed to address these misconceptions.

The technical report on the project (Hind et al. 2001) concluded that overall the interventions provided by the lessons had been successful in broadening the profile of views about the nature of science which some of the students in the sample drew upon in response to a specific context. However, there were also a number of students for whom these single interventions had little effect judging by the evidence of their evaluative probes. Furthermore, observations and interviews with teachers highlighted the difficulties for teachers in teaching about the nature of science, something that for many teachers is unfamiliar.

---

[32] The lessons developed and trialled by the Teaching about Science project can be downloaded from the Nuffield Foundation website: http://www.nuffieldfoundation.org/teaching-about-science (accessed in March 2012).

63.17 An Alternative Approach to Teaching the History and Philosophy of Science

63.17.1 Origins of the Perspectives on Science Course

The Perspectives on Science course has its origins in conversations about the need for a qualification which would give post-16 UK students an opportunity to explore and develop their own ideas concerning topics related to the history and philosophy of science.[33] The course development process was initiated by Becky Parker, John Taylor (both science teachers) and Elizabeth Swinbank from the University of York Science Education Group. The rationale for developing the qualification was that students enjoy discussions in which issues relating to the epistemology and metaphysics of science are raised but that there is often little scope for exploring these during science lessons due to lack of time (Taylor 2012). Moreover, it was felt that providing students with an opportunity to explore 'the human face of science' by a study of the history of science would help them to develop a more realistic understanding of the nature of science and also help to break down the divide between 'scientific' and 'humanities' styles of thinking. It was felt too that study of the history and philosophy of science had value in helping to develop students' skills in critical thinking (Swinbank and Taylor 2007).

63.17.2 The Perspectives *Approach to Teaching the History of Science*

In certain respects, the *Perspectives on Science* course was similar in aim and design to the *Science for Public Understanding* course described above. Both developments exploited the opportunity afforded by changes in the post-16 national curriculum, specifically the introduction of the 'AS-level'. Both were developed in a context in which there was growing emphasis on the importance of developing the scientific literacy of students (Millar and Osborne 1998) and both therefore aimed to help students to develop their ideas about science.

However, the *Perspectives on Science* approach was distinctive in a number of respects. Firstly, it was not developed as a science qualification but as a programme in the history and philosophy of science. Whilst the course materials drew on scientific cases studies, the programme of study was designed to teach students how to apply the methods of historical and philosophical analysis to scientific material, rather than to teach them more science. Moreover, the qualification aimed to give a central place to pedagogical techniques, such as classroom discussion and debate,

---

[33] See Bycroft (2010) for further discussion of the development of the course.

more commonly associated with humanities subjects, and to teach students how to produce extended research dissertations.

Secondly, the course developers deliberately chose a different approach to the question of how ideas about science should be taught than that embodied in the *Science for Public Understanding* course. Whilst the *Science for Public Understanding* course developers selected a list of ideas about science which were taught as part of the prescribed course content, the *Perspectives on Science* chose not to use any such list. The course was designed specifically to allow students the opportunity to develop their own ideas. There was in fact no prescribed course content. Instead, the programme of study was constructed in such as way as to teach students the skills they needed to begin thinking for themselves about historical and philosophical questions relating to science. The aim of the course was to teach students *how* to think in these ways, not *what* to think. The course materials did use a series of case studies, in which issues from the history and philosophy of science were introduced, but these were selected because they were felt to provide good contexts for the skills of historical and philosophical research and analysis, rather than because they were thought to contain essential subject knowledge.[34]

A third distinctive feature of the *Perspectives on Science* was the mode of assessment. The course was unique amongst post-16 UK AS-level qualifications in that assessment was entirely by means of a student research project and oral presentation and not by means of a written exam. This mode of assessment was felt to be the most suitable, given that the aim of the course was to encourage students to develop their own ideas through processes of research and argumentative discussion. Students were allowed to make a free choice of topic for their dissertation, although guidelines existed to lead them towards research questions which were well focussed, with links to research literature and with scope for analytic thought and argumentative engagement.

As Edgar Jenkins (1994) points out, the common feature of most attempts to include insights from the history and philosophy of science in school curricula is that the teaching is assumed to be essentially supportive of the goals of science education itself; it is not expected to challenge its traditional purposes. This is where *Perspectives on Science* opened up a new line of development, allowing teachers and students to respond directly, and in its own terms, to scholarship in the history and philosophy of science. One student, for example, chose to write a project in which she argued that witch-hunting was a scientific activity (witch-hunters based their conclusions on evidence and carried out trials). The historical component of her project was informed by documentary research involving a visit to a county records office to read records of witch trials, and, philosophically, she drew on Feyerabend's radical critique of the notion of scientific method. Another student chose to write about the extent to which the problem of the incommensurability of rival paradigms undermines the idea of objective progress in science.

---

[34] The student and teacher guides for the course provide further details (Perspectives Project Team 2007a, b).

These examples illustrate the way in which students had a degree of freedom which was unusual in courses which are part of a national qualification framework to engage with scholarly arguments and challenge conventional conceptions of the nature of science.[35]

The point made in Ziman (1994) about the tendency of courses in the history and philosophy of science to endorse oversimplified, Whiggish interpretations of the history of science was addressed by the use of carefully constructed case studies which embody good historiographical practices, including contextualization of scientific developments, exploration of rival conceptual schemes and the exploration of historically complex narratives, such as that of the developing understanding of oxygen, or the recent controversy about cold fusion, which act to counter the idea that the history of science is a tale of steady progress towards an agreed-upon truth.[36] Students addressing projects with historical dimensions were expected to apply these techniques in writing literature reviews, which showed critical awareness of issues such as source reliability and objectivity, and manifested awareness of the wider context within which the developments they discuss took place. The successful application of these techniques of historical analysis formed one strand in the assessment criteria for the dissertation.

63.17.3 The **Perspectives** *Approach to Teaching the Philosophy of Science*

The approach to the philosophy of science was determined by the fact that the aim of the course was to equip students with the knowledge and skills to begin to develop their own philosophical ideas about topics related to science. This was achieved in the programme of study by using a sequence of lessons designed to help students develop skills in critical thinking and conceptual analysis. In most cases, the lessons involved little didactic instruction, although some teaching of common philosophical frameworks took place. Topic areas addressed include science and religion, the nature of scientific truth, genetics, animal welfare, medical ethics, the mind, artificial intelligence, free will and determinism, pseudoscience and the paranormal. Case

---

[35] Examples such as these may reawaken the concern expressed – with tongue-in-cheek – by Brush (1974) about the risk that teaching students the history of science will have the damaging consequence of subverting a convergent realist interpretation. But as Brush himself concludes, it can be argued that helping students to develop a more realistic picture of how scientists behave will have ‘redeeming social significance’. As Matthews (1994/2014, p. 7) notes, HPS programmes can humanise the sciences, and there is evidence that this makes science programmes more attractive to students, particularly girls. It was this thought which informed the approach of the *Perspectives on Science* course. In this connection it is worth pointing out that both of the projects exemplified above were written by girls, one of whom chose to change from studying History at Cambridge to studying History and Philosophy of Science because she had found it such an enjoyable subject.

[36] The history of science section of the *Perspectives on Science* course was written by Peter Ellis, with John Cartwright contributing a section on the discovery of oxygen.

study material from these subject areas was used as a stimulus for classroom discussion and debate, the aim of these discussions being to engage student interest, as well as to help strengthen students' ability to engage in reasoned argument. To this end, teaching about argument structure was integrated into the programme of discussion of philosophical topics.

Inevitably, a short course in the philosophy of science can only provide an introduction to a select number of the central debates in the field. The written dissertation provided the context for greater depth of study of a specific research question with an historical and/or philosophical dimension. So, for example, a student who found discussion of philosophical questions linked to genetics particularly interesting might choose to study the question of whether autism has a genetic cause, and as part of this, to explore in greater depth the way the concept of causation functions in such a setting.

63.17.4 Teaching and Teachers

In 2007/2008, a team from the Institute of Education at the University of London carried out a research study of *Perspectives on Science* (Levinson et al. 2008, 2012). The researchers noted that discussion topics mostly tended to involve ethical questions, which tend to be very effective in helping students engage in discussion as the substantive knowledge needed is quite accessible. They noted that diversity, passion and extreme viewpoints amongst students can be productively harnessed. They also noted that there were far fewer projects which focussed on the history of science (a point further discussed in Bycroft 2010) and urged that teachers should try to address more challenging philosophical and historical issues as students' discussion skills develop.

The research study of the *Perspectives on* Science course echoed others (Monk and Osborne 1997) in noting teachers' problematic lack of knowledge of the philosophy of science. This is an area which teachers who felt that they would like further training identified as the one in which they were most in need of additional support.

63.17.5 Implications for Science Education

The *Perspectives on Science* course ran as an AS pilot between 2004 and 2008. In the final pilot year, 31 UK schools taught the course. As a small-scale programme, the question arises as to whether it constitutes another instance of the observed failure of programmes in the history and philosophy of science to contribute to mainstream science education (Monk and Osborne 1997).

Despite its small size, the *Perspectives on Science* course has some claim to have had an influence on wider educational developments and to have the potential to contribute to mainstream science education. This is mainly because of the part it has played in shaping the *Extended Project Qualification*, which was launched nationally in 2008 and which by 2011 attracted almost 25,000 student entries. This qualification provides post-16 students with an opportunity to carry out a major research project on a topic of their own choice. The *Perspectives on Science* course served as a model for the dissertation unit of the *Extended Project* offered by the Edexcel awarding body. A number of elements of the *Extended Project* dissertation model, namely, an emphasis on the writing of an historically focussed literature review, with critical evaluation of source objectivity and reliability and consideration of context, use of philosophical reasoning in addressing issues which are not susceptible to empirical resolution and exploration of ethical issues arising from scientific and technological developments, derived directly from the approach piloted in the *Perspectives on Science* course.

The *Extended Project* also offers a Field Study/Investigation unit, and this unit provides an opportunity for in-depth scientific investigation, with the construction of hypotheses, data collection and analysis which involves exploration of the extent to which data supports hypotheses. Significantly for the purposes of teachers wishing to integrate elements of the history and philosophy of science within their science teaching, *Extended Project* investigations also require students to show awareness of the wider context of their research, and this can lead them in the direction of historical study or exploration of social, economic or ethical issues related to their investigation. So, for example, one student carried out an investigation with the title ‘Global warming: Anthropogenic or Astronomical’, in which he researched the recent history of one aspect of debate about the causes of climate change then went on to experimentally test the hypothesis that cloud cover could be affected by cosmic ray flux. Another student carried out an investigation under the title ‘What is the most effective method of producing aspirin and is it justifiably described as a ‘wonder drug’?’, in which she researched the history of the development of aspirin, explored the controversy about who first synthesised acetylsalicylic acid, examined the way aspirin is presented in the media, discussed problems of access to aspirin in less economically developed countries and then carried out a laboratory comparison of the yield of two different synthetic pathways to a precursor of aspirin.

Currently, the number of students who are writing *Extended Projects* in which scientific questions are explored in this contextual manner, with consideration of ethical, historical and philosophical aspects, or with links to empirical work, is not large. But it is significant that this work is beginning to take place as part of mainstream science education, at least at post-16 stage. Monk and Osborne (1997) noted that science teachers will begin to engage with the history and philosophy of science only insofar as it can be shown that this engagement contributes to their students’ examinable knowledge and skills. As a result of the development of the *Extended Project,* informed by the *Perspectives on Science* course, there exists a national qualification, the assessment criteria of which have been shaped to be conducive to gaining a deeper understanding of scientific topics, as well as others, by means of historical and philosophical enquiry.

63.18 Conclusion

Despite 50 years of exploration and over 20 years of the national curriculum's treatment of the history of science and the nature of science, there is still no consensus in England about the ideas-about-science that should feature in the curriculum. This is shown, for example, by the public debate that followed the introduction of 'how science works' into the curriculum (Perks 2006). Over the period covered by this chapter, it is notable how long it has taken to bring about systemic change.

Despite the slow pace of change, much has been learned about the conditions needed to introduce teaching about the history and nature of science into mainstream science education. One lesson is that it is important that new courses lead to recognised qualifications even during the pioneering phase. It is also important that methods of assessment are devised that reward teaching and learning in line with new aims. A significant reason why it has taken so long to embed teaching about the nature of science into the everyday thinking and practice of science teachers is that it has proved difficult to specify the intended learning outcomes in language that is widely understood and accepted. This has the consequence that it has been difficult to devise assessment items for examinations that encourage good practice in schools.

Another barrier to change has been that teaching about the nature of science can be a formidable challenge to those teachers whose own education and training has not helped them to reflect on the history and philosophy of science themselves. At the very least, dissemination of ideas and teaching methods beyond an initial group of enthusiasts depends on the production of high-quality resources in print and other media. In England the production of such resources, especially in the early stages, when their commercial value was in doubt, has been heavily dependent on support from number of charitable foundations. Opportunities for professional development are important too, but they have generally not been provided on a large enough scale to change the general culture of science teaching.

The English experience shows that it is crucial that the course content and teaching methods are rooted in the practical realities of school classrooms. All the early developments described in this chapter grew out of the interests of teachers. Subsequently some of these teachers moved into curriculum development and into universities, without losing interest in the field. Thus grew up a strong and enduring partnership between practitioners in schools and academics in higher education. The footnotes and bibliography for this chapter reflect the fruitfulness of this collaborative approach with their mixture of references to a great variety of tried-and-tested resources as well as references to research papers and scholarly articles.

An extraordinary feature of the science curriculum in England since the introduction of the first national curriculum in 1989 has been the rapidity of change. New versions of the science curriculum for students aged 14–16 were published in 1989, 1991, 1995, 2000 and 2004. The curriculum for those aged 11–14 was also revised in 2006. Further change is underway following the election of a new government in 2010. This government has abolished the curriculum authority, QCA, so that changes to the curriculum are now under the direct oversight of ministers. This is a complete reversal of the situation in the 1960s when politicians kept out of 'the secret garden'[37] of the curriculum.

In its first statements about the new science curriculum, the Department for Education[38] has stated that one of the aims should be that students develop their understanding of the nature, processes and methods of science. However, the approach is likely to change and the term 'how science works' will almost certainly disappear from official documents. An early draft of the curriculum suggests that in the future students should develop their understanding of these aspects of science through practical activity.

The development of many of the initiatives discussed here derived from the desire to create curriculum space for discussions of questions about the history and philosophy of science to be taken further. The *Perspectives on Science* approach pioneered the use of such discussions as a catalyst for independent student enquiry and project work. It has recently been argued (Taylor 2012) that teaching itself should be seen as a philosophical activity and that, to counter the tendency of assessment to determine pedagogy, teachers should focus more on equipping students to think critically and enquire independently in all areas of study. It has also been argued that conceptual understanding, which is fundamental to all learning, presupposes a grasp of the historical and philosophical matrix within which scientific knowledge exists (Blackburn 2010). If these arguments can be sustained, in the teeth of an educational culture dominated by the pressures of high-stakes assessment and accountability measures, it may yet come to be recognised that ideas emerging from the history and philosophy of science teaching community can be beneficially applied to mainstream science education.

Acknowledgments We are grateful for advice from Peter Ellis, Edgar Jenkins (University of Leeds, UK), Robin Millar (University of York, UK), Jonathan Osborne (Stanford University, USA), Michael Reiss (Institute of Education, University of London, UK) and Jim Ryder (University of Leeds, UK). We are also grateful to Ralph Levinson, Michael Hand and Ruth Amos at the Institute of Education, University of London, UK, for sharing their research findings ahead of publication.

[37] The term 'secret garden' was popularised in connection with a speech by the Labour Prime Minister Jim Callaghan in 1976. He started a debate that led in time to the national curriculum. He argued that it should not be teachers alone that determine the curriculum but that parents, learned and professional bodies, representatives of higher education and both sides of industry, together with the government, all have an important part to play in formulating and expressing the purposes of education and standards.

Dr. John L. Taylor is Head of Philosophy and Director of Critical Skills at Rugby School. He studied Physics and Philosophy at Balliol College, Oxford before going on to do research in Philosophy and teach Philosophy of Science at the university. In 1999 he moved to Rugby School to teach physics. He has directed the Perspectives on Science project. He is a Chief Examiner for the Extended Project and a Visiting Fellow of the Institute of Education.

Andrew Hunt is science consultant to the eLibrary of the National STEM Centre. He studied Natural Sciences at Cambridge before teaching in four contrasting schools over 20 years. During that time he was also a contributor, as writer and examiner, to the development and assessment of the Nuffield Chemistry courses. Subsequently he took on leading roles in a series of curriculum development projects for the Nuffield Foundation, the Association for Science Education and the University of York Science Education Group. He was the first director of the Nuffield Curriculum Centre until 2007 where he was responsible for oversight of major projects in science, technology and mathematics. He is author and editor of a variety of chemistry textbooks and multimedia resources. He is chair of examiners for the AQA A-level Science in Society course. In 1988, Andrew was awarded the Royal Society of Chemistry Award in Chemical Education. He received an honorary doctorate at the University of York in 2009.

Chapter 64
Incorporation of HPS/NOS Content in School and Teacher Education Programmes in Europe

Liborio Dibattista and Francesca Morgese

64.1 Government Policies and Recommendations for the Teaching of Science with the Historical-Critical Approach

64.1.1 Europe

The crisis of scientific vocations has been a pressing subject in the agenda of developed countries, and the relationship between the *crisis of scientific education and social, political and economic development* has been widely acknowledged. The question had already arisen in the White Paper *Teaching and Learning: Towards the Learning Society* (European Commission 1995): facing rapid changes, the widening of the exchanges to a world dimension, the rise of the information society and rapid progress in science and technology. There was a *paradoxical* reaction by European citizens that would see as a *threat* and with *irrational fear* the scientific and technological innovations. These should instead have been considered as instruments for the acquisition of new competences and competitiveness on the job market.

The 1995 European Commission document hoped for the involvement of initiatives and actions for the diffusion of culture and scientific and technological information that might emphasise the value of science and technology for the progress of humanity. Promoting *general culture* and *scientific culture* in this case was meant as a support for the society of knowledge: 'Clearly this does not mean turning everyone into a scientific expert but enabling them to fulfil an enlightened role in making choices which affect their environment and to understand in broad terms the social implications of debate between experts. There is similarly a need to make everyone

L. Dibattista (✉) • F. Morgese

M.R. Matthews (ed.), *International Handbook of Research in History, Philosophy and Science Teaching*, DOI 10.1007/978-94-007-7654-8_64,

capable of making considered decisions as consumers' (p. 11). Traditional science teaching, aiming at the mastery of a strictly logic order, of the deductive system, of abstract notions among which mathematics dominate, seems to paralyse and to make a passive subject of the learner, suffocating his imagination.

The finger was pointed at the tendency of teaching to 'present[ing] the world […] as a completed construction', and member states were invited to promote initiatives for the introduction of the history of science and technology as part of science education.

The debate on education *tout court*, and particularly on scientific and technological education, was dealt with later by the commissions of a number of European Councils. The one in Lisbon in 2000 (European Council Lisbon 2000) identified for the decade 2000–2010 the goal of making European economy *knowledge based*: 'the most competitive and dynamic knowledge-based economy in the world, capable of sustainable economic growth with more and better jobs and greater social cohesion', confirming the relationship between education, training/growth and European economic development. After Lisbon, the new 'noticeable' issue has been to promote the *candidateship of scientific and technical studies*, one of the objectives discussed in the European Council of Stockholm 2001 where it was asserted that European competitiveness needs a number of mathematics and science experts and it is dangerous that these studies are deserted by European youths, who show a negative attitude towards them and an inferior learning to expectations (European Council Stockholm 2001).

The need to *attract more students to technical and scientific studies* has become from that moment one of the *leitmotif* of the European documents: in Barcelona (European Council Barcelona 2002), for example, they proposed a 'general renewal of pedagogy' and the use of 'development strategies aiming at the performance of schools in encouraging pupils to study natural science, technology and mathematics and in teaching these subjects'. In Brussels (European Council Brussels 2003), the objective to be achieved was an increase of 15 % in the number of graduates in mathematics, science and technology. Subsequent European Councils would monitor and record the implementation of the Lisbon strategy and the achievement of the objectives proposed in the preceding years.

In this panorama are included the huge survey campaigns on the level of learning of European students, to which Italy too has been participating for at least 30 years (INVALSI 2008).

In short, these documents strongly stressed *education/economic development* and the need to for scientific culture to *renew its methods* and *teaching practices.* On closer look, however, there is not a precise indication with regard to the strategies to follow in order to achieve such renewal.

The first document to express more practical insight on the subject was the 2004 report released by the European Commission, *Europe needs more scientists!* (European Commission 2004), a series of recommendations aimed at increasing European human resources in the fields of science and technology. For the first time, a finger is pointed extremely clearly at the 'perception' of science that students form during their school years and which seems to be one of the most significant reasons for young people's difficulty in imagining themselves working in the future in a scientific career. School, by continuing to insist on 'counter-intuitive concepts and abstract ideas with no relevance to their daily lives', continues to immerse students in a context void of any real and deep understanding of science. Member states are invited to enrich their science curricula with wide-ranging interdisciplinary relationships between science, technology and other disciplines, with historical considerations which are neither stereotyped nor anecdotal and with wide-ranging and significant reflections on the nature of science (p. 138).

The 2005 survey called *Special Eurobarometer: Europeans, Science and Technology* had pointed out that 50 % of the European citizens interviewed agreed with the statement: 'science classes at school are not sufficiently appealing' (European Commission 2005, p. 99, 102), so it is the way science is taught in schools that turns off interest towards scientific subjects. The survey devoted a special section to the analysis of *scientific studies and the mobilisation of young people* to monitor European citizens' awareness about the role of science in society and to understand the causes for the loss of interest in scientific studies. What the survey showed was a *lack of understanding* of scientific and technological matters and a general feeling of *distance* from such issues.

Similar conclusions emerge from a survey made in 2006 (OECD 2006; European Commission 2006) on the evolution of young people's *interest* in science and technology: once again, formal scientific education is taken as the cause for the lack of natural curiosity towards science, this being even more serious since 'student choices are mostly determined by their image of S&T professions, the content of S&T *curricula* and the quality of teaching'.

These discussions and statements on scientific education have produced many of the research projects and teaching activities that will be illustrated in the second part of this chapter, one of which will be the description of the ROSE project.

The international[1] comparative project ROSE (the Relevance of Science Education) collected and analysed data on the factors that influence young people's perception of science and technology in scholastic and extra-scholastic contexts and reasons for the choices students make about whether or not they continue to study science. The target population is students towards the end of secondary school (age 15) and the research instrument is a questionnaire. The objective of ROSE is to collect enough information to develop proposals that will affect policy decisions in terms of scholastic curricula, reduce the extent of differences between the actual science and technology curriculum and that which the students would like to learn about and reinforce the relevance, attractiveness and quality of S&T education (Schreiner and Sjøberg 2004).

The reports of numerous countries which participated in the project[2] and a general summary which identifies the main results of the project are currently available (Sjøberg and Schreiner 2010). These reports show widespread interest on

---

[1] About 40 countries have taken part or are taking part in ROSE. http://roseproject.no/.

[2] http://roseproject.no/publications/english-pub.html; http://roseproject.no/publications/other languages.html. For Italy, see Neresini et al. (2010).

the part of 15-year-olds in the subjects of science and technology, especially for those issues with more easily perceivable links to daily life and future work and professional possibilities. At the same time, knowledge of the importance of science and technology for society seems to be widespread among youth. However, the judgment of the relevance and attractiveness of the scientific disciplines studied at school[3] is more negative in the more highly developed nations than it is in those with a lower (HDI).[4]

Generally, in European countries the scientific subjects studied at school are seen to be important but difficult to understand, and this perception deters students from imagining themselves working in scientific professions in the future: '[…] school science fails in many ways' from the inability to involve students to the inability to arouse their curiosity, from shortcomings in making occupational possibilities perceivable to shortcomings in helping students to appreciate nature (Sjøberg and Schreiner 2010, p. 11). Additionally, it can be seen that students give a low rating to the interest of the contents present in texts and in the curricula. Low to average approval was found for knowledge about famous scientists and their lives, while high values were found for knowledge of the applicative 'context' of science and technology. An important result of the project is that 'there seems to be a need to 'humanize' school science, to show that science is part of history and culture' (Sjøberg and Schreiner 2010, p. 30).

A key document in the field is the so-called Rocard report (European Commission 2007) which finds new strategies to be implemented in teaching through the identification and promotion of *inquiry-based science education* (IBSE) and *problem-based learning* (PBL). This document promotes non-rote teaching based on abstract information and a teaching model based on the *processes of science* and on how it is practised, on concepts *transmitted through concrete experience*, on rich laboratory work, but most of all, an experience in which *learning proceeds through problem-solving*.

Since *problem-solving* implies the need to gather information, to identify the possible solutions, to evaluate in a critical way all the alternatives and show the conclusions, it would allow the students to engage in *active learning*, through the *building* of their own scientific knowledge. Teaching should rely on *concrete examples* as a way of providing access to understanding of the science.

Therefore, school being the most appropriate educational institution for providing training in scientific culture and career counselling, we reckon it is the place where these initiatives should be carried out.

We must clarify that the European documents have just an advisory value for member states and do not have compulsory effects on educational policies.

A detailed report prepared by the Eurydice European Unit on behalf of the Directorate-General for Education and Culture della European Commission (Eurydice 2011) contains a comparative investigation of regulations and official

[3] Sixteen questions in the ROSE questionnaire focused on the assessment of this area (*My science classes*).

[4] Human Development Index.

recommendations on the subject of science teaching in Europe. Significantly, the title of executive summary is ‘Countries support many individual programmes, but overall strategies are rare’. In fact:

> Few European countries have developed a broad strategic framework to raise the profile of science in education and wider society. However, a wide range of initiatives have been implemented in many countries. The impact of these various activities is nevertheless difficult to measure … Most European countries recommend that science should be taught in context. Usually this involves teaching science in relation to contemporary societal issues … The more abstract issues relating to scientific method, the ‘nature of science’ or the production of scientific knowledge are more often linked to the curricula for separate science subjects which are usually taught in the later school years in most European countries. (Eurydice 2011, p. 9)

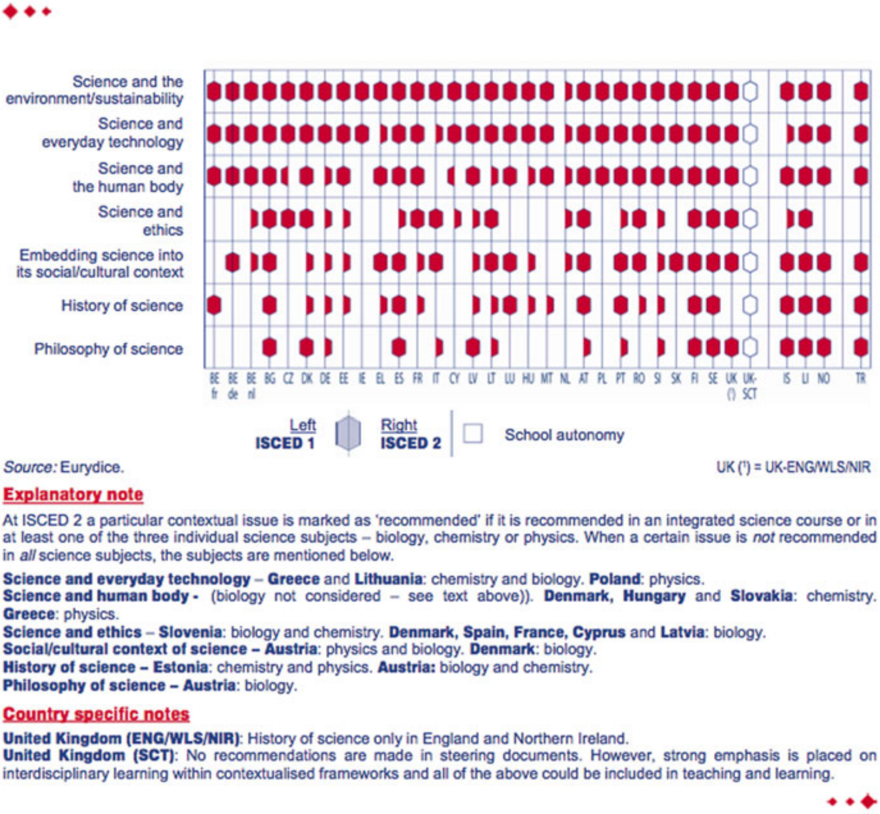
Moreover,

> Context-based science teaching emphasises the philosophical, historical or societal aspects of science and technology, as well as connecting scientific understanding with students’ everyday experiences. This approach is considered by some researchers to increase students’ motivation to engage in scientific studies, and possibly lead to improved scientific achievement and increased uptake. The science-technology-society approach requires science to be embedded into its social and cultural context. From a sociological perspective, this includes examining and questioning the values implicit in scientific practices and knowledge, looking at the social conditions as well as the consequences of scientific knowledge and its changes, and studying the structure and process of scientific activity. From a historical perspective, changes in the development of science and scientific ideas are studied. From a philosophical perspective, context-based science teaching raises questions regarding the nature of scientific inquiry and evaluates the grounds of its validity. It also recognises science as a ‘human endeavour’ where imagination and creativity play a role.
>
> Embedding science into its social/cultural context is considered important when teaching because the development of scientific knowledge may be viewed as a social practice which is dependent on the political, social, historical and cultural realities of the time. The process involves examining/questioning the values implicit in scientific practices and knowledge, looking at the social conditions as well as the consequences of scientific knowledge and its changes, and also studying the structure and process of scientific activity. At primary level, this approach is recommended in approximately half of European education systems. At lower secondary level, embedding science into its social and cultural context is suggested in 27 educational systems. The history of science is recommended in less than half of European education systems at primary level. At lower secondary level, the history of human thought about the natural world (from its beginnings in prehistoric times to the present) is suggested in more than half the European countries. The least common contextual dimension in science teaching at ISCED[5] 1 and 2 is the philosophy of science. Only about one third of European education systems at primary level and about a half of countries at lower secondary level suggest addressing questions regarding the nature or validity of scientific inquiry.(ibidem, pp. 65–66)

Figure 64.1 from the Eurydice report (reproduced after this paragraph) illustrates in which countries and at what level of education the *curriculum* for science teaching in primary and lower secondary education refers to science in context, either in terms of the history of science or contemporary societal issues or both.

---

[5] ISCED: International Standard Classification of Education by UNESCO. (1) Primary education, (2) lower secondary, (3) upper secondary.



Source: Eurydice. UK (¹) = UK-ENG/WLS/NIR

Explanatory note

At ISCED 2 a particular contextual issue is marked as 'recommended' if it is recommended in an integrated science course or in at least one of the three individual science subjects – biology, chemistry or physics. When a certain issue is *not* recommended in *all* science subjects, the subjects are mentioned below.

Science and everyday technology – **Greece** and **Lithuania**: chemistry and biology. **Poland**: physics.
Science and human body - (biology not considered – see text above)). **Denmark, Hungary** and **Slovakia**: chemistry. **Greece**: physics.
Science and ethics – **Slovenia**: biology and chemistry. **Denmark, Spain, France, Cyprus** and **Latvia**: biology.
Social/cultural context of science – Austria: physics and biology. **Denmark**: biology.
History of science – Estonia: chemistry and physics. **Austria:** biology and chemistry.
Philosophy of science – Austria: biology.

Country specific notes

United Kingdom (ENG/WLS/NIR): History of science only in England and Northern Ireland.
United Kingdom (SCT): No recommendations are made in steering documents. However, strong emphasis is placed on interdisciplinary learning within contextualised frameworks and all of the above could be included in teaching and learning.

Fig. 64.1 Contextual issues to be addressed in science classes, as recommended in steering documents (ISCED 1 and 2), 2010/11

An update of this framework can be found at https://webgate.ec.europa.eu/fpfis/mwikis/eurydice/index.php?title=Home, where the 'Eurypedia (European Encyclopedia on National Educations Systems)' provides current information on national education systems of 38 European countries. The same report provides some news about improvements to science teacher education. In particular, it emphasises the relevance of improvement of teachers' views of the nature of science (NOS):

> In a professional development programme focusing on scientific modelling, teachers improved their views of NOS and inquiry as they expanded their definitions of science from a knowledge-based orientation to a process-based one. Furthermore, an informed understanding of the NOS can be enhanced by the use of meta-cognitive strategies (Abd-El-Khalick and Akerson 2009) and it seems that pre-service teachers who receive explicit instruction in the nature of science as a stand-alone topic are more able to apply their understanding of the nature of science appropriately to novel situations and issues than teachers learning within the context of a case such as for instance, climate change. (p. 104)

Many European countries are conducting programmes and projects for improving science teachers' skills. The survey SITEP (Survey on Initial Teacher Education

Programmes in Mathematics and Science) conducted by the Eurydice unit at the EACEA, which closed in late 2011, demonstrated no significant changes in teachers' approach. As a matter of fact, 'the most important competence addressed in teacher education is the knowledge and ability to teach the official mathematics/science curriculum'. However 'creating a rich spectrum of teaching situations, or applying various teaching techniques, is usually a part of a specific course in both generalist and specialist teacher education programmes. Applying collaborative or project-based learning and inquiry- or problem-based learning is frequently addressed in both types of teacher education programmes'.

The uniformity of the curricula in terms of competence, learning and, as a consequence, of certification and evaluation of the courses of study is something that Europe aspires to, as also shown by the publication of *The European Framework for Key Competencies*[6] (European Parliament 2006) and the *European Qualification Framework* – EQF[7] (European Parliament 2008) – which are two fundamental documents from the viewpoint of EU cooperation in education and lifelong learning. The European viewpoint is to promote collaboration between member states in view of the consolidation of a common European base of key skills and the facilitation of international exchanges and labour mobility. Nevertheless, we are still far from the attainment in Europe of uniformity in terms of science curricula at the level of primary and secondary instruction and also of teacher training.

An important European initiative which intends to enhance the range of quality of research in science education in Europe is ESERA (European Science Education Research Association),[8] formed at the European Conference on Research in Science Education held in Leeds, England, in April 1995. ESERA is an association of European science educators which aims to provide a forum for collaboration in science education research between European countries and to relate research to the policy and practice of science education in Europe. Through the organisation of conferences and the publication of reports, ESERA aims to highlight the major issues facing formal secondary science education, identify similarities and differences between countries and make a series of recommendations for improvement in key areas.

The latest report published, *Science Education in Europe: Critical Reflections* (Osborne and Dillon 2008), contains the conclusions of science educators from nine European countries. There are brief recommendations that analyse the current situation in science education in Europe and lay out the desired prospects for the future. Perhaps the most striking of these is the first recommendation which predicts the obligatory teaching of the nature of science (NOS) in secondary schools, while courses in individual scientific disciplines would become electives available to students who wish to prepare for careers in science. This is exactly the opposite of the current situation in European secondary schools. The reasoning behind this recommendation lies in the perception of standard science teaching as being both of

[8] http://lsg.ucy.ac.cy/esera/index.html

little use and unappealing, based on the rote learning of abstract concepts, at a time when there is a need to provide students with basic knowledge of how science works and skills that will prepare them to address the problems of modern life and be informed citizens. On the other hand, the type of preprofessional training provided by a curriculum of single scientific disciplines ends up distancing youth from the prospect of undertaking a career in science.

The other recommendations underline aspects of science in context, the need for more female science teachers in the schools and the importance of early intervention since studies have demonstrated that student interest in science already begins to decline after age 14. Additionally, it is hoped that European governments will invest in the recruitment and support of a highly qualified teaching force, to be recognised both economically and socially, and realise the importance of modifying the current systems for evaluating abilities, knowledge and skills, which at this time focus too heavily on content performance tests such as the PISA. *Developing and extending the ways in which science is taught is essential for improving student engagement. Transforming teacher practice across the EU is a long-term project and will require significant and sustained investment in continuous professional development.* Finally, in the opinion of the report's authors, the best way to obtain this kind of science education for students lies in the study of the history of science and reflections on the epistemology and ethics of scientific enterprise.

In May 2011, the *Scientix Conference*, the conference of the community for science education in Europe, was held in Brussels. *Scientix* is a project of *European Schoolnet*, a network of 31 European Ministries of Education, supported by the European Commission. *Scientix* gathers and coordinates information on activities and results in the field of science instruction, including projects financed by the sixth and seventh European Union Framework Programmes, the initiatives of the *Lifelong Learning Programme* of the DGEC (*Directorate-General for Education and Culture*) and national initiatives. The key ideas set forward in Brussels highlighted how great the need is for scientific literacy in Europe, how important it is for educational policies to be coordinated with the needs of the workplace, how it is necessary to develop creative curricula and innovative teaching practices and how all of this is fundamentally related to the recognition (formal, intellectual, economic and political) of the key role played by teachers in European schools. John Holman, at that time director of the British *National Science Learning Centre*, mentioned in the welcome address, among other topics, the issue of how fundamental it is that teaching innovation be conveyed through curricula able to transmit, in addition to scientific contents, a clear idea of the *nature of science*, hence of the epistemology that structures scientific knowledge. If the magic formula is *inquiry-based science learning*, the questions and problems that produce 'science' as their answer are best learned by studying their history and philosophy. However, after this splendid inaugural declaration, epistemology and the history of science disappeared from the presentations at the Belgian conference.

In conclusion, in European policies on science education we can report a decrease in the emphasis given to the historical-philosophical approach during the last

15 years. As a matter of fact, in the final findings of the 1998 Strasbourg conference, conducted by Claude Debru, about the *History of Science and Technology in Education and Training in Europe*, it was expected that:

> all European students in science, technology or medicine should be strongly encouraged to attend a special course in the history of science, technology or medicine at least once during their studies. This teaching should be delivered at undergraduate level, as a element of general culture … Compulsory courses in history of science and technology should be part of the training received by science teachers at universities, so that they can convey a more dynamic view of science in their subsequent teaching at secondary schools…Students of history, philosophy and the social sciences should receive a specialized course in the history of science and technology at least once during their curriculum. The course should be compulsory in the training of future school teachers … The teaching of the history of science and technology should be systematically introduced in institutes devoted to the training of secondary-school teachers. (Debru 1998)

Eight years later, during the 2nd International Conference of the European Society for the History of Science, the round table discussion conducted by Claude Debru on the same argument showed no substantial changes; on the contrary:

> We should encourage the interest of DG (Directorate General) Research which lost interest in the Humanities in recent years after some signs of interest for master programmes … One relevant aspect lies in the intensified economic pressure on universities. This results in a challenge towards several academic disciplines that can have neither many students nor many third-party funds. Unfortunately, among these disciplines is also the history of science (P. Heering). (Kokowsky 2006)

Thirteen years later, sadly we cannot but repeat the account from Pietro Corsi in Strasbourg: ‘History of Science: Star of Research, Cinderella of Education’ (Corsi 2000).

64.1.2 Italy

The European guidelines have been acknowledged by the member states through initiatives, research and interventions that have contributed to bringing up the question of *scientific culture* in ministerial agendas and have engaged with public opinion, thus better defining the outlines and the content of the problem. In Italy, the fundamental question has been: *which factors are responsible for the falling interest in science and hamper the desire of the young in taking up a career in science?*

A common answer is that sciences per se do not arouse interest, since they are difficult and demanding disciplines (whether this is true or just a stereotype, prompted by an established cultural tradition, is the object of much research) and that a scientific degree, with the commitment and hard work employed in the process, does not necessarily turn into a well-paid and lasting profession.

However, these views do not coincide with those who work in science museums and science centres that are now quite widespread, including in Italy. They witness growing curiosity, interest and enthusiasm in the students who take part in educational visits as extra-school activities (Rodari 2008). This is an interest that seems to arise ‘only outside the classes and the departments’ (Crespi et al. 2005; Gouthier and Manzoli 2008, p. 143), and it has been predicted that it is rather ‘a positive involvement that will gradually fade away with the passing of the years’ (Cigada 2007).

These external contexts to the school world show that the problem lies in the *teaching methods*, in the *content*, in its *tools* and in the *methodologies* that are employed in the teaching process of scientific disciplines and also in the *image of science* that formal education conveys. Moreover, the formal organisation of school, compared with the non-formal approach of science centres, is an additional issue. The question seems to be the *lack of correspondence* between practised science and taught science in school. By *lack of correspondence* we mean to say that the way that science is taught and learnt leaves out the reconstruction of the problems that led scientists to carry out their research and the reasons that led them on the path that they undertook. We would like here to cite an expression of Dario Antiseri: ‘there is an urgent need, in the teaching of sciences, to make students *stumble* onto the problems’ (Antiseri 1977, pp. 111–112). If science is to be intended as *construction*, why are the students denied the access to the way in which this construction happened in the past and still happens now?

Some important experiences show that the active involvement of students in building, elaborating and communicating scientific paths transforms itself into motivation and learning. As an example of this, we can indicate an initiative called *Scienza under 18* (Science under 18), a regional council project, promoted by the Regional School Office of Lombardia (Italy), that has worked on the valorisation of the didactic experimentation and public communication of science by the students themselves for about a decade.[9]

In Italy, an important step, in accordance with the European and Italian debate, has been the creation in 2006 of the *Interministerial Work Group for the Development of the Scientific and Technologic Culture*, recently re-established as *Committee for the development of scientific and technological culture* (July 2010).[10] This institution has the role of drawing up guidelines to support the diffusion of scientific culture and the improvement of the quality and efficacy of education in the field. The documents produced make the same assumption that *science* is *culture*, a *way of knowledge*, and that as such it has to be explicated in the *curriculum*. The renewal of teaching proposed there does not only imply an in-depth study of the content matter of science but also of the discourse on science and scientific work, aiming at the student’s building and personal re-elaboration of the knowledge (Documento di lavoro 2007, pp. 3–4) in synergy with the professional development of teachers, for whom a lifelong training is necessary.

The case against superficial factual knowledge teaching leads to the identification of key objectives to be achieved: to update *teaching methods*, which, in fact, are not introducing young students to experimental inquiry; to lead them to the pleasure

---

[9] http://www.scienza-under-18.org. Accessed 23 January 2011.

[10] http://archivio.pubblica.istruzione.it/argomenti/gst/ and http://www.istruzione.it/web/ministero/scienza-e-tecnologia. Accessed 23 January 2011.

of discovery and to a *taste for problem-solving*; to enhance systematic laboratory practice, to facilitate the development of activities like observation, measuring, handling and building; to diversify and enrich *didactic tools*, being too often only represented by *low-quality textbooks* (Fierli 2004); and to introduce a *humanised approach* with special attention given to *historic contextualisation*, 'to be considered as the understanding of the way and the time in which the concepts have been dealt with and the way the discoveries have been made'.

The aim is to make a *historical approach* to scientific disciplines and their connection to the *humanities* highly recommended; to situate the birth of concepts, of theories and of inventions in their social and cultural context; and to highlight the role of science and technology in the history of mankind.

In short, the finger is pointed against an idea of science presented without an epistemological, historical, dynamical and sociocultural approach, in which the description of the results has the priority over science making, in which scientific theories are presented as an absolute thing, to be learned in rote fashion, in the form of statements and principles, without any interdisciplinary approach. In addition, the new approach stresses the importance of the formative power of scientific culture, something that has long been neglected by the philosophic tradition and in Italian teaching practice (Morgese 2008).

However, though considered a priority in the Italian ministerial courses of study, these remain only hints and programme statements, since no specific document on the historical contextualisation of the *humanistic approach* and on the *connection between the sciences and humanities* has been issued (Morgese 2010b).

We recall the workshop, organised by the *Work Group* called *Per un nuovo liceo 'scientifico' nel XXI secolo. Fondazione culturale e rilevanza sociale* (1–2 April 2009) (Towards a new 'scientific' senior high school for the XXI century. Cultural foundation and social relevance), which constituted one of the preparatory tasks to the secondary school reform currently in force in Italy. The workshop moved in this direction, with the aim of promoting a debate among those in schools, universities and research on the cultural structure and the curriculum of senior high schools that award the science diploma,[11] which are the secondary schools with the greatest number of accepted applicants in Italy. The main issue was the reflection on the cultural and formative value of the science curriculum that it must be based on the '*holism of the project*, on the correct integration between the humanist-social component and the scientific one … not as a cold addition of the two disciplines but as a unified course' (Berlinguer 2009) in order to allow, for the different disciplines, the promotion of an integrated knowledge and the acquisition of scientific culture as the heritage of a community, not just for those who will take up a career in that field (Gouthier 2009a, p. 3, b).

Finally, though only as an initial recognition, in Italy, the importance of the issue was acknowledged through the introduction of references to this matter in the recent

---

[11] Diploma is the qualification you get at the end of five years in high school; there are two types of Lyceum in Italy: *Liceo Classico* (Diploma in Classical Studies) and *Liceo Scientifico* (Diploma in Sciences).

National Guidelines concerning the specific learning objectives of high school courses. Specifically, it is prescribed for mathematics, physics and the natural sciences that the theories studied should to be set in the historical, philosophical, scientific, social, economic and technological environment within which they developed (see below).

Starting in the 2010–2011 school year, a *reform of the secondary level of education* was implemented in Italy.[12]

The objective of the new system is to revitalise the quality of secondary school education, intended as the ability to provide the student with 'the cultural and methodological tools for an in-depth understanding of reality, so that he can, in a rational, creative, active and critical way, deal with situations, phenomena and problems and acquire knowledge, abilities and skills in line with his capacities and personal choices and suitable for the continuation of higher level studies, for integration into social life and the world of work' (Regulation, Art. 2, Comma 2, cited in MIUR 2010a).

The reform was accompanied by the publication of ministerial reference documents. Two that are essential for a clear understanding of the new system are *profilo educativo, culturale e professionale (PECUP) dello student/educational, cultural and professional student profile (PECUP)* (MIUR 2010c) and *indicazioni nazionali/national indications* for high school courses of study (MIUR 2010b). The PECUP defines the student profile at the conclusion of the high school programme in terms of knowledge, abilities and skills. The document calls for a complete evaluation of all aspects of the student's scholastic work, in particular including 'the study of disciplines from a systematic, historical and critical perspective'. The centrality of the historical and critical perspective can be clearly inferred from the ministerial auspices. Firstly, these aspects are referred to as the result of common learning to be cultivated across the board in all six types of high school in the educational system. In particular, it is explicitly called for in the humanistic historical area,[13] in which the profile calls for the ability 'to contextualize scientific thought, the history of its discoveries and the development of technological inventions in the greater sphere of the history of ideas'. However, it is revealing that this proficiency is absent from the scientific, mathematical and technological area.

Thus, it can be inferred that the promotion of the development of this proficiency is basically entrusted to teachers of history and philosophy and not to teachers of scientific and mathematical disciplines. Secondly, the historical perspective is constantly referred to as the result of learning, even in the distinct high school courses of study. At the end of each high school programme, the student must be able appropriately and knowledgeably to place specific cultural products within their historical and cultural contexts.

---

[12] This reform reordered the secondary school system into six types of academically oriented high schools and divided the professional institutes into two sectors, for a total of six courses of study, and the technical institutes into two sectors, for a total of 11 courses of study.

[13] One of the five areas that the results of cross-disciplinary learning are divided into at the academically oriented high schools. The others are the methodological area; the logical-argumentative area; the linguistic and communicative area; and the scientific, mathematical and technological area.

The national indications are the PECUP's guidelines for each discipline: teachers look to this document when creating their course outline so that their students can reach the objectives for learning and the acquisition of skills provided for in high school education. Therefore, the national indications basically focus attention on the disciplines to be studied, analysing them from two points of view: (1) from the point of view of the *competencies*[14] expected at the end of the course of study and (2) from the point of view of the ongoing *specific learning objectives*, aimed at the achievement of competencies, structured in disciplinary units relative to each 2-year period and to the fifth year. At the same time, a few core disciplines are identified: Italian language and literature, foreign language and literature, mathematics, history and sciences.

The guiding principles of the national indications are the following:

1. The *unity of knowledge*, with no separation of the 'notion' from its transformation into a skill. It is explicitly stated that 'Knowing is not a mechanical process, it implies the discovery of something that enters through the sensory process of a person who 'sees,' 'realizes,' 'tests,' and 'verifies,' in order to understand'.
2. *Interdisciplinarity*: the need to build a dialogue between the various disciplines for a coherent and homogeneous profile of cultural processes. The indications take on the task of highlighting the fundamental points of convergence, the historical moments and the conceptual connections that require the joint intervention of more than one discipline to be understood to their true extent.

As in the case of the PECUP, the national indications also make abundant reference to the historical dimension of knowledge, understood as 'reference to a given context' and to the need to promote that dimension in all disciplines of study to ensure that students obtain critical and mindful knowledge.[15]

---

[14] The recommendations of the European Parliament and Council, 23 April 2008, in the European Qualifications Framework for Lifelong Learning, define this competency as 'Proven capacity to use personal, social and/or methodological knowledge, abilities and capacities in situations of work or study and in personal and professional development'.

[15] For mathematics, the student must know how to set the various mathematical theories studied in the *historical context in which they were developed*, understand their conceptual significance and have acquired a *historical-critical vision of the relationships between the main themes of mathematical thought and the philosophical, scientific and technological context*. It is explicitly stated that 'This articulation of subjects and approaches will be the basis for *establishing connections and comparisons* in concepts and methods with other disciplines like physics, natural sciences, philosophy and history'. For physics, at the conclusion of the course of study, the student will have learned the basic concepts of physics, acquiring knowledge of the *cultural value of the discipline and of its historical and epistemological evolution*. For the natural sciences, the subject matter should be proposed following the historical and conceptual development of the single disciplines, both temporally and as per *their links with the entire cultural, social, economic and technological context of the periods in which they were developed*. These links must be made explicit, through underscoring the reciprocal influences in the various spheres of thought and culture. A student completing the humanities high school course of study must also know how to contextualise scientific thought within the humanistic dimension. A student completing the scientific high school course of study must be aware, especially in physics, of the connection between the development of the knowledge of physics and the historical and philosophical context in which it developed.

The introduction in Italy of the reform was accompanied by a national convention[16] and by a series of seminars[17] aimed at teachers and principals, which included presentations by members of the commission for national indications and by representatives of the academic, productive and research fields. The relationships regarding the role and nature of science education in the reform show that the writers of the national indications were aware of the cultural value of the teaching of scientific disciplines with a historical, contextual and epistemological approach, referred to particularly in the presentations by Tommaso Ruggieri (2010), Giorgio Bolondi (2010), Nicola Vittorio (2010a, b) and Andrea Battistini (2010),[18] all of which are available on the website dedicated to the reform. What is missing, however, is any explicit reference to the results of national and international research on the use of the history and philosophy of science in teaching. Also missing are materials in this field of research which could be accessible for teachers on the web portal dedicated to the reform. Therefore, it seems that there is a gap between the national indications and the results of research.

Nonetheless, we would like to focus the reader's attention on one point: within the total hours for scientific disciplines, which are already few, there is no specific course time scheduled for the introduction of contents regarding the history and philosophy of science.

Moreover, the ability of the teacher to design interdisciplinary courses of study and to create connections between mathematics, the scientific disciplines and history and philosophy is entrusted to the free choice, competence and sensibility of the teachers themselves. Therefore, it is not part of their training, nor is it indicated as a practice that must necessarily be part of the teaching profession. The history of science is practically absent from the training of teachers, both pre-service and in-service.

Ministerial Decree 249/2010 (MIUR 2010d) redefined the initial training of Italian teachers at all levels. Therefore, starting in the 2011–2012 academic year, Italian universities instituted degree courses and Active Internship Training (TFA) courses for graduate students preparing to teach in the schools. The scientific field 'history of science and technology' is almost completely missing and is actually completely left out of the course of study for future teachers of history and philosophy at academically oriented high schools. The history of science and technology is taught to teachers who will teach philosophy, psychology and educational sciences in human sciences high schools, while it is an elective course (and with fewer course

They are both members of the commission for the national indications http://www.indire.it/lucabas/lkmw_file/licei2010/Decreto%20n.%2026%20del%20%2011%20marzo%202010.pdf.

hours than the mandatory courses) for future teachers of mathematics, sciences and technology in junior high schools (Bernardi 2011).

This appears to be a step back from what was required for the initial training of teachers prior to Ministerial Decree 249/2010. Previously, starting in 1998, teacher training was entrusted to specialised teacher training schools for secondary education (SSIS), a 2-year postgraduate training course required of anyone wishing to become qualified as a high school teacher. In the SSIS programme, study of the history of science and technology was obligatory for teachers of mathematics and scientific disciplines.[19] This experience was interrupted after nine cycles: in 2009, the activity of the SSIS was brought to a stop (Anceschi and Scaglioni 2010).

We wonder, then, how it is actually possible for teachers to teach science with an historical approach when this dimension is absent from their training. Moreover, a lot of questions arise: the guidelines are not based on the results of national or international research on the use of history and philosophy of science in science teaching, and there is a lack of availability of reference materials available for teachers. Finally, the time devoted to science teaching is far from enough to make possible an approach where history and philosophy of science can play an important role.

64.2 The Historical-Critical Approach: Concrete Experiences in Europe and Italy

In this section, we illustrate a few initiatives, projects and teaching activities fielded in Europe and Italy with the aim of carrying out the European recommendations outlined in the previous section of this chapter, and we illustrate the profile of some associations and research institutions dealing with education projects that have HPS/NOS as content.

64.2.1 Europe

In Europe, it is possible to identify a few recent experimental proposals that blend scientific education with the historical-critical approach.

---

[19] The SSIS Apulia was a special case in that history of science and technology was a cross-discipline course for the teachers of all subjects (Dibattista and Morgese 2011). The aim of the course of 'history of science and technology' in SSIS Apulia was the didactic application of the discipline through the training of both science and humanities teachers. The result of the ten-year experience was the publication of a book, with the collaboration of some trainees of the various SSIS courses, that displays a series of actual proposals, usable case studies for the teaching of science in an interdisciplinary way and is based on the historical-critical approach (Dibattista 2008).

HIPST (*History and Philosophy in Science Teaching*)[20] has organised the collaboration of international research groups in order to produce and develop case studies for teaching and learning science with the historical-critical method oriented towards the discovery of NOS and the inclusion of the production of scientific knowledge in authentic contexts.

The theoretical assumption of the point of departure is that scientific concepts are more easily understood if presented in the historical context of their discovery, rather than presented in the decontextualised and systematic manner typical of the traditional didactic approach. The tools used were the production of teaching materials, in the form of case studies; documentation by the teachers involved in the study; and the formation of a solid network of science teachers, researchers and institutions which disseminate scientific culture, with the objective of collaboration in synergy for the implementation of the project and its follow-up (Höttecke and Riess 2009; Höttecke and Henke 2010, 2011).

In the initial phase of the project (1–16 months), a collection was made of materials related to the current teaching practices and activities in each partner country in the area of science teaching and learning, so as to establish a starting point on which to build the following project phases. The second phase of the project (16–28 months) was dedicated to the creation of a corpus of case studies on the basis of the national needs which had emerged in the previous phase, for example, on the basis of their adaptation to the study programmes in force in each nation. The corpus, translated into the various languages of the partner countries, was distributed and put into practice. The last phase of the project (29–30 months) was the period of the transfer of know-how, the fine tuning and distribution of the materials produced and their evaluation. All of the material produced was made accessible online.[21]

The Catalan Society for the History of Science and Technology (*Societat Catalana d'Història de la Ciència i de la Tècnica* – SCHCT) created a pilot course in the history of science for in-service teachers sponsored by the Department of Education (Departament d'Educació)[22] in Catalonia. The courses,[23] taught online with the Moodle learning management system, were held during 2009–2010 (Science and Technology through History) and 2010–2011 (the History of Mathematics and Science for Secondary Education) academic years, and more

---

[20] The project, financed as part of the Settimo programma quadro (FP7, *The Seventh Framework Programme*, 2007–2013), had a duration of 30 months and concluded in July 2010, http://hipst.eled.auth.gr/. Project participants included ten partners from seven European nations and Israel.

[21] Available on the platform hipstwiki: http://hipstwiki.wetpaint.com/. The section of the corpus of *case studies* developed over the course of the project is at page http://hipstwiki.wetpaint.com/page/hipst+developed+cases.

[22] http://www20.gencat.cat/portal/site/ensenyament

[23] The course was presented at the symposium *La Història de la Ciència i de la Tècnica en l'Ensenyament i en la Formació del Professorat* dell'VIII *Congreso Internacional sobre Investigación en la Didáctica de las Ciencias* – Enseñanza de las Ciencias en un mundo en transformación, Barcelona, 7–10 September 2009, http://ice.uab.cat/congresos2009/eprints/cd_congres/propostes_htm/htm/inici.htm.

than 50 % of those enrolled completed the courses. The same introductory module was used to present the history of science and its use in teaching for the three modules specific to the teaching of mathematics, physics and biology. The greatest achievement of the initiative was that the teachers learned about the effectiveness of making use of primary sources, such as the writings of Galileo, Newton and Darwin. The greatest difficulty lay in the fact that the course was perceived as a university course in the teaching of the history of science, rather than as a tool developed specifically for school teaching (Grapì 2009, 2011; Massa and Romero 2009). The initiative is part of a change which took place in Catalonia between 2007 and 2008 with the adoption of a new curriculum for secondary education[24] which places at the centre of the teaching-learning of science the discovery of NOS, the historical context of scientific knowledge and the relationships between science, technology and society, and that, as a consequence, makes specific teacher training necessary. A similar situation can be found in the new study programme for mathematics, in which the knowledge of a few notions of the historical genesis of key events in mathematics is included (Grapì 2009).

Nevertheless, the history of science is not currently a mandatory discipline in the training of future teachers, and curricula in the history of physics, chemistry, biology or mathematics are optional. The CAP (*Certificado de Aptitud Pedagogica* – the certification for the qualification to teach in secondary school), in force until 2009, included the possibility to attend one or two sessions dedicated to the history of a particular scientific discipline. The current *Master en Formacion de Profesorado* includes in the Especialidad de Matemáticas only an obligatory module on ‘History of Mathematics’ and one on ‘Mathematics, Society and Culture’.

The current Spanish curriculum, issued by the Education Law (2006), includes HPS/NOS contents in compulsory and high school education through two ways: on the one hand, through the definition of the key competence in science as a cross-curricular keystone for the curricula of all science subjects and, on the other hand, through the design of common specific content for science subjects. The specific common contents designed for the curricula of science subjects involve a miscellaneous set of issues that can be grouped into the following categories: searching for information and using information technologies (ICTs); compliance with safety and operating standards in the laboratory; autonomy and creativity; processes of scientific inquiry; and science, technology and society.

Though the former categories include some aspects related to HPS/NOS issues, the latter display the core of HPS/NOS contents for science subjects. These include the recognition of the role of scientific and technological knowledge on social development and people’s lives; the recognition of the importance of scientific knowledge to make decisions about objects and about yourself; the assessment of the contributions of the natural sciences to meet the needs of human beings and improve the conditions of their existence; the appreciation and enjoyment of natural and cultural diversity; and the contribution to their conservation, protection and improvement, the recognition of the relations among science (physics, chemistry,

---

[24] Ley Orgànica 2/2006, http://noticias.juridicas.com/base_datos/Admin/lo2-2006.html.

biology and geology) to technology, society and the environment and the potential applications and implications of their study and learning. Further, the institutionalisation of a specific subject, called Science for the Contemporary World, provides the longest and most systematic list of HPS/NOS content. The subject is compulsory for both science and nonscience students in high school (eleventh grade). It focuses on scientific and technological literacy by addressing current issues that are important for the general citizen.

The situation in higher education degrees is quite complex at the moment; on the one hand, similarly to Italy, it greatly depends on the research interests at each university; on the other hand, it is now changing due to changes to curricula to adapt them to Bologna guidelines, so that until the process is complete, little can be said about it. Finally, the initial training of teachers is also influenced by the development of the Bologna process. In the case of primary teachers, as science is for them just one subject among many other subjects to learn, the HPS/NOS contents are scarce. In the case of secondary and high school teachers (a single group in Spain from the view of initial training), the master's degree must prepare teachers to teach the science curricula, and thus, as the HPS/NOS curricular issues detailed above are compulsory, it must follow that HPS/NOS issues should be part of the master's training.

The ATLAS (Active Teaching and Learning Approaches in Science) group of the School of Primary Education at the Aristotle University of Thessaloniki has created a web tool (atlaswiki) that allows its teacher-users to find (and propose) relevant materials for the creation of teaching units, starting with the history of science (Kouloumtzos and Seroglou 2007).

Moreover, the Institute of Neohellenic Research of the National Hellenic Research Foundation in collaboration with the Laboratory of Science Education, Epistemology and Educational Technology (ASEL) of the University of Athens, Greece, started the History, Philosophy and Didactics of Science Programme (HPDST) (http://www.hpdst.gr) that is active in publishing journals and monographs of historical and scientific interest and in the organisation of symposia and conferences and has launched the project Hephaestus (Hellenic Philosophy, History and Environmental Science Teaching Under Scrutiny), funded under the FP7, currently ongoing and aiming to improve the activity of the programme in the field of history of science, educational activities and dissemination of scientific information and results.

More actions funded by the European Community through FP7 and are relevant to this review are as follows:

SONSEU (Science on Stage Europe), a European initiative designed to encourage teachers from across Europe to share good practice in science teaching, which publishes *Science in School*, a European journal for science teachers which often proposes papers about history and philosophy of science

MATERIAL SCIENCE, a partnership of six European Universities from Cyprus, Finland, Greece, Italy and Spain for the design and implementation of research-based ICT-enhanced modules on material properties. The project has a strand of educational resources based on the HPS (insights from the history of science and technology).

In France, the group Patrimoine, Histoire des Sciences et des Techniques (PaHST) at the University of Brest, in addition to the study of the scientific and industrial patrimony, is also active in the use of the history of science and epistemology in the teaching of the sciences. The group took part in the project ‘Mind the Gap’ in the cluster of projects financed by FP7 which attempt to meet the needs highlighted by the aforementioned Rocard report. In 2010, it organised a European workshop, History of Science and Technology Resources and Methods for Inquiry-Based Science Teaching (IBST), and it manages a block of courses at the University of Brest dedicated to HST, IBST and cultural mediation in science (Laubé 2011).

Still in France, the HPM[25] – History and Pedagogy of Mathematics – an international study group on the relations between the history and pedagogy of mathematics affiliated to the *International Commission on Mathematical Instruction* (ICMI), should be noted. By combining the *history* of mathematics with the *teaching and learning* of mathematics, the group aims at stressing the conception of mathematics as a living science, a science with a long history, a vivid present and an as yet unforeseen future. Among the group’s activities of particular interest are the satellite meetings at the *International Congress on Mathematical Education* (ICME), organised by ICMI every 4 years with the aim of disseminating and exchanging considerations on and practices in the use of the history and epistemology of mathematics in teaching.

Among the HPM’s recent activities, of particular interest was the organisation in Nantes on 4–6 July 2011 of the international conference *European Perspectives in the Use of History in Mathematics Education*, dealing with the developments of research in the field of the use of history in mathematics education, with particular reference to Europe.

Another activity worthy of note is the organisation of the *European Summer University on the History and Epistemology in Mathematics Education* (ESU). These are conferences which are moments of reflection and international exchange on the use of history and epistemology in mathematics education and bring together a network of teachers, researchers in education and historians. The proceedings are a landmark in the evolution of this approach. A high point of the ESU conferences is the teachers’ participation in the activities in close collaboration with the results of research. The initiative of organising a Summer University (SU) on History and Epistemology in Mathematics Education belongs to the French Mathematics Education community in the early 1980s.

In France, the network of IREMs[26] – Instituts de Recherche sur l’Enseignement des Mathématiques – organises conferences and seminars that focus on reflection, research and training teachers in how to integrate the historical approach in teaching mathematics. The research group also produces teaching materials (reprints of original sources, reports on classroom activities, teaching plans) which are the result of

---

[25] For the history of the founding group in 2000, see the document available at http://www.clab.edc.uoc.gr/HPM/HPMhistory.PDF. The group’s website is at http://www.clab.edc.uoc.gr/HPM/INDEX.HTM. The HPM Newsletter is at http://grouphpm.wordpress.com/.

[26] http://www.univ-irem.fr/spip.php.

the hands-on classroom experience of teachers who participate in the IREM network. Ongoing activities worthy of mention include the organisation of the international conference *La didactique des mathématiques: approches et enjeux. Hommages à Michèle Artigue,*[27] 31 May–2 June 2012, which included among its topics of discussion consideration of the practices and research in the history and epistemology of mathematics in the teaching of mathematics (Plenary Lecture *Epistemology, History and Didactics*; Atelier *Epistemology and Didactics*).

A group of five European universities (Kapodistrian University of Athens, University of Pavia, University of Oldenburg, University of Cyprus, University of Thessaloniki) has created, as part of the actions of the European Union's Comenius 2.1, the STeT, Science Teacher e-Training project. This project, financed in 2006 as the continuation of a similar programme – the MAP project of 2004 – has created a series of tools which use case studies from the history of science to provide in-service science teachers with innovative materials to help them reconceptualise their views in some important teaching and learning aspects of science education and gradually transform their teaching practice. Currently, the Kapodistrian University of Athens coordinates five other partners (University of Flensburg, University of Brest, Polish Association of Teachers, Diamantopoulos School and the University of Winnipeg) in a new Comenius multilateral project named *Storytelling@Teaching Model* (S@TM) that started in 2011 and will end in 2013. This aims to enhance the professional development of science teachers by the use of case stories from the history of science, building a digital resource kit based on the storytelling teaching method.

The Scientific and Technological Research Council of Turkey (TÜBİTAK) is the leading agency for managing, funding and conducting research in Turkey. Thanks to funding provided by TÜBİTAK's 1001 programme, which funds scientific and technological research projects, the University of Marmara carried out a project for the development of teaching materials specifically developed for the teaching of modules on the history of science in secondary schools and tested its effectiveness on a sample of teachers of scientific disciplines (Irez et al. 2011).

One of the most complex projects for the integration of the history and philosophy of science into the coursework of preuniversity level students is the Perspectives on Science course which has currently been assessed as an Extended Project Qualification, an accepted qualification for university entrance in the UK. Developed by the Centre for Innovation and Research in Science Education, Department of Education, University of York, the course has the main goal of providing students with, in addition to the typical subject matter of the history, philosophy and ethics of science, the development of critical thinking skills typical of the epistemological approach. The goal is not only to prepare them for study in science after they leave school but, more generally, to foster an inquisitive, rational approach to life in general. For this reason, the course does not require acquisition of specific subject matter, but after an introductory phase in which the students learn how to use source materials and develop skills in philosophical and ethical argumentation and logical

---

[27] http://www.colloqueartigue2012.fr/

reasoning, they must analyse case studies in the history of science and produce an individual research project. This dissertation takes the place of a final examination and must be defended orally. The teaching of the course and the evaluation of the final dissertation is carried out by the teachers from the institutions which have adopted the qualification[28]; this introduces the question of the training of teachers for a type of didactics based on the contextual and cultural dimension of science. This issue was addressed through the creation of teaching materials[29] and an *in-service training* programme.[30] The objectives of the course are to foster the mental skills that make it possible for the students to address science's 'big questions', to develop research and argumentation skills and to be open to ethical debate (Taylor and Swinbank 2011).

Moreover, the University of York, in partnership with the Nuffield Foundation, developed the Twenty First Century Science qualification, a suite of General Certificate of Secondary Education (GCSE) courses that 'meet[s] the needs, through flexible options, of those who will go on to be professional scientists and of those who will not'. The materials are designed to achieve scientific literacy through an understanding of ideas about science and science explanation. Basically, this is the realisation of the wishes from the Nuffield report that we have previously mentioned.

Still in the UK, mention should be made of the HIMED (History of Mathematics in Education) conferences, run by the Education Section of the British Society of History of Mathematics (BSHM). These were established in 1990 and promote the use of history in mathematics education (Fauvel and van Maanen 2000).

Finally, in the catalogue of the initiatives of scientific instruction collected by the STENCIL project (Science Teaching European Network for Creativity and Innovation in Learning (http://www.stencil-science.eu/)), it is possible to find numerous localised activities in European schools which use the history of science as a tool for teaching scientific disciplines. For brevity's sake, we will only point out here *Maths in Wonderland* in Romania, *Maths to Play* and *History, Maths, History of Mathematics* in Italy and *Energy is our Future* in Belgium.

---

[28] In 2008, approximately 30 secondary schools participated in the project; in 2011, more than 700 institutes in the UK are taking advantage of this opportunity.

[29] A *Student Book* (Perspectives on Science Project Team 2007a) and a *Teacher Book* (Perspectives on Science Project Team 2007b) have been produced. Both are organised by *case studies* related to scientific problems and questions which are explored in their historical, epistemological and ethical dimensions and offer ample study materials. For example, the *Student Book* is organised as follows: Part 1: *Researching the History of Science,* Part 2: *Discussing Ethical Issues in Science,* Part 3: *Thinking Philosophically about Science*, and Part 4: *Carrying out a Research Project*.

[30] These are courses carried out during the school year both residentially and not. They introduce the teachers, of both scientific and humanistic disciplines, to the historical, epistemological and contextual approach to science, to the strategies for developing an active and dialogue-based method of teaching, to the development of *case studies* and to the writing of and *coaching* for the final dissertation.

64.2.2 Italy

In highlighting the existing situations, we distinguish between university research groups and professional teachers' associations.

64.2.2.1 University Research Groups

The university research groups listed carry out theoretical research on the methodologies for science teaching-learning, also developing operative projects for teacher training and orientation, and for the production of didactic materials.

University of Pavia: Group of History and Didactics

Historically, the oldest and better established group in Italy devoted to this matter is the Group of History and Didactics of the University of Pavia, which has worked with the aim of introducing the history of science in school curricula, especially through conferences and publications (Bevilacqua et al. 2001; Bevilacqua and Fregonese 2000–2003).

The activity of the group is focused on the identification of tools and methodologies that can contribute to the improvement of the teaching-learning of physics and the issues related to the initial and in-service training of junior and senior high school teachers, with an eye to developing innovative approaches to the teaching of physics, including the historical developments in the field of physics and the use of new technologies.

The *Group of History and Didactics* of the University of Pavia participated in the PRIN F21[31] project, *Percorsi di Formazione in Fisica per il 21° secolo/Physics Training Courses for the twenty first Century*, carried out in 2006 by University of Naples 'Federico II' under the scientific direction of Prof. P. Guidoni and in collaboration with various university groups of Italian researchers.

Within the F21 PRIN, the Pavia group was involved in the production of *teaching-learning sequences* (TLSs) for teachers of scientific disciplines, set in the wider panorama of research on TLSs. The TLSs implement the historical approach in the teaching of friction, in the belief that the role of the history of science is particularly effective and justifiable in this specific subject because it helps teachers:

> to clearly position recent developments, which have opened new areas and issues of research. A short historical overview, in addition to looking back at the characters and episodes of the past, serves to draw attention to recent events and future prospects, working together to

---

[31] PRIN is the acronym which indicates 'research programmes of considerable national interest'. An overview of PRIN F21 is available at http://www.ricercaitaliana.it/prin/dettaglio_prin-2004020419.htm. For the part of the programme regarding the Pavia group, under the scientific direction of Prof. Paolo Mascheretti, see http://fisicavolta.unipv.it/didattica/SeqAttr/xxx.html and http://www.ricercaitaliana.it/prin/unita_op-2004020419_006.htm.

> show how this is a subject of current interest and study. It also makes it possible to provide simplified but effective insight into the issues regarding the subject, while learning about its complexity, linked to the diversity of materials and situations, and the theoretical uncertainties, revealed in interpretative controversies which have not yet been entirely resolved.

Additionally, the Pavia group has produced *the Pavia Project Physics – Gateway for the Circulation of Scientific Historical Culture* (http://ppp.unipv.it). The research carried out by the group is divided into three areas:

- Science history and philosophy: to position research on scientific knowledge within its cultural, institutional and social contexts and the context of the philosophies of nature that scientists explore and to more correctly contextualise the products of science
- Science education: research and experimentation with constructivist methodologies of teaching-learning which stimulate students' ability to formulate and resolve problems and to be active creators of their own scientific culture
- Digital technologies: the construction of hypermedia with differentiated approaches for different levels which facilitate the proliferation and personalisation of learning paths in physics

The products created by the group include:

- The analysis of *case studies* of the history of physics from Galileo to the modern day, with particular interdisciplinary focus on the relationships between scientific concepts and philosophical, religious and epistemological concepts
- Restoration and appreciation of primary sources, including the work of identifying and cataloguing collections of scientific tools and library collections
- Development and testing of learning activities for various scholastic levels on the basic concepts of physics, also through the use of ICT tools and multimedia, along with the production and testing of teaching modules for training physics teachers
- The creation of websites and teaching hypertexts with simulations of scientific experiences and the use of two-dimensional and three-dimensional presentations and animations to illustrate the theoretical principles of physics or how tools used in this field work
- A series of books, including essays, studies, catalogues of collections and teaching guides, also available on CD-Rom, exhibits, teleconferences and television programmes

These projects and products were tested as part of the course in physics, chemistry and the natural sciences for high school teachers.

University of Rome 'La Sapienza': Dipartimento di Fisica

Other important contributions in this direction are the activities of the research group of Dipartimento di Fisica of University of Rome 'La Sapienza' about the history of thermodynamics (Tarsitani and Vicentini 1991). Of particular interest is the didactic and research activity of Carlo Tarsitani, professor of the foundations of physics, regarding the history and philosophy of physics (developments in the field of physics in the nineteenth and twentieth centuries, history of quantum physics, conceptual foundations and the philosophical implication of quantum mechanics) and didactics of physics (the study of the conditions that could make possible the effective teaching of the physics of the twentieth century, in the final years of secondary school) (Tarsitani 2009).

University of Bologna: Physics Department

The Bologna group is identified around the didactic and research activity of Silvio Bergia, Grimellini Tomasini and Olivia Levrini. Here, we intend to focus on their considerations regarding the history and philosophy of science as effective tools in the teaching of physics in the SSIS programme (the *teacher training specialising course for high school teachers*) of Bologna. The materials developed for the didactic activity of the SSIS of Bologna concern space-time physics (from classical mechanics to the basic ideas of general relativity) and represent the results of a process of educational reconstruction, in which subjects' aspects are integrated with historical-epistemological and cognitive considerations with the following criteria: privileging the quality of knowledge rather than the quantity of notions to be transmitted, addressing topics and questions of twentieth century physics on the basis of a 'modern teaching' of classical physics, and fostering an image of physics as a 'cultural product' characterised by a coexistence of different interpretations of the same formalism and the interconnections with other cultural fields (Grimellini Tomasini and Levrini 2003).

University of Udine

The second level interuniversity master's degree in 'Didactic Innovation in Physics and Orientation' (M-IDIFO3)[32] (De Ambrosis and Levrini 2010), with headquarters at the University of Udine, is part of the Scientific Degree Programme (PLS) and is one of the most important Italian programmes for the orientation of teachers in the didactics of physics. A part of the didactic programme is dedicated to historical content (20 h of the history of cosmology from antiquity to Einstein and 30 h of laboratory work on the historical evolution of the concept of time).

University of Bari

We want to highlight two further innovative experiences in Italy regarding the teaching of science with an historical approach. They are both projects funded by the Italian Ministry of Education, University and Research (MIUR) in the sphere of funding designated for the dissemination of scientific culture (Law 6/2000) and

---

[32] Coordinated by M. Michelini, Udine, as part of the Scientific Degree Project.

were both designed and directed by the Centro Interdipartimentale Seminario di Storia della Scienza dell'Università degli Studi di Bari 'Aldo Moro'/Centre for the Interdepartmental Seminar on the History of Science at the 'Aldo Moro', University of Bari. The seminar has, for many years, worked at training teachers, both pre-service and in-service, in the use of the historical and philosophical approach to science education.

The first project, *La storia della scienza va a scuola/The History of Science Goes to School*, was conducted during the 2009–2010 academic year and was a practical experience in introducing the history and philosophy of science into junior and senior high school classrooms in Apulia (Italy). The many schools which participated made use of the historical-scientific teaching modules through the case study approach. In the first phase, the participating teachers were trained by university tutors in how this particular teaching approach works. In the second phase, the teachers taught the modules in their classes, and, finally, these modules were presented at a concluding conference. The effectiveness of the project was also evaluated through questionnaires created specifically for this purpose.

Over 20 in-service teachers of scientific and humanistic subjects and over 400 students participated in the project.

The positive results of the research were the following: efficacy in communicating the scientific subject matter, learner (and teacher) openness to issues regarding the nature of science, the fact that the students gained a more comprehensive view of science and great student enthusiasm for publicly demonstrating the work they had done. Same critical points were the extra time and work that the teachers were required to devote to this project, on the one hand, to prepare the modules and, on the other, because of the lack of ad hoc teaching aids (Dibattista 2010). The project's products are 15 interdisciplinary didactic proposals in the form of case studies described by the teachers in a collective volume (Dibattista 2010), each one including an illustrative analytical file: the disciplines involved in the study case, the type of students it was aimed at, the prerequisites, the cognitive and metacognitive objectives, the methods and tools used, the timeframe, the proposals for verification and a bibliography.

The second project, *Il Racconto della Scienza – Digital Storytelling in Classe/The Story of Science – Digital Storytelling in the Classroom*, was conducted during the 2011–2012 academic year and was the result of a competition held in the junior and senior high schools of the Apulia region. Participants were asked to create multimedia products using the technique of Digital Storytelling to narrate a historical-scientific episode or the story of a scientist. Objectives were to promote the introduction of innovative approaches to teaching scientific disciplines, based on the history and philosophy of science, and solicit the production of highly personalised digital learning environments, created by the users themselves, starting from the specific didactic needs of each group-class and centred on narrative practice. Given the innovative nature of the methodology required to create the products, the teachers in charge of the classes entered in the competition completed a training programme on the history of science and audiovisual technologies, carried out at the University of Bari. Nineteen senior high schools and 13 junior high schools from the Puglia region participated. Over 40 teachers of scientific and humanistic disciplines and over 800 students participated in the project.[33] Twenty-four *Digital Storytelling* courses with historical-scientific content were produced by the schools. The project evaluations, carried out through the administration of questionnaires to teachers and students ex ante and ex post, are currently being processed. The project's final publication will include the description of the creation process of the winning Digital Storytelling courses, starting from the historical-scientific case study chosen as the topic; how the Digital Storytelling course fits into the framework of studies on digital learning environments; and the evaluation of the project, starting from the results of the questionnaires.

A recent project, *Performascienza. Laboratori teatrali di storia della scienza a scuola (Performascienza. Theatre Workshops of History of Science at School)*, involved historians of science and pedagogists of the University of Bari 'Aldo Moro' in the promotion of theatre workshops on history of science case studies in the junior and senior high schools of Bari and in the provinces. The project was carried out by *Scienz@ppeal Association*[34] of Bari and took place in 5 months of the school year 2009–2010. The project applied the dramatisation of *case studies* involving a wide range of actions, such as monitoring the scientific imagination of the teachers and of the students, the teaching practices of the science teachers and the receptiveness of the schools and of the territory in the diffusion of scientific culture. Finally, it involved an evaluation of the efficacy of the case study methodology, through the means of narration and drama, in building an interdisciplinary and complex *scientific literacy*. The products of the project are three videos which illustrate the process of carrying out the project in the three participating schools and a final publication (Morgese and Vinci 2010) which contains the narration of the case studies realised through theatre in the schools, the evaluation of the experience by the tutor teachers in each school, the evaluation of the project on the basis of the results of the questionnaires and a discussion of how the project fits into the framework of studies on the historical approach in science teaching.

64.2.2.2 Professional Associations of Teachers

Teacher associations listed below primarily perform guidance and training of teachers.

ANISN

The *Associazione Nazionale degli Insegnanti di Scienze Naturali/National Association of Natural Sciences Teachers* (ANISN)[35] is addressing scientific education using the historical-critical method.

---

[33] The winners received their awards on 16 December 2011 at the Bari Cittadella Mediterranea della Scienza at an event attended by over 350 students and their teachers. The list of the digital storytelling winners and the reason for which they were chosen are available at www.scienzappeal.com.

[34] www.scienzappeal.com

[35] http://www.anisn.it/

ANISN is an association of teachers, scientists and enthusiasts founded in 1979 with the aim of promoting and increasing the professionalism of natural science teachers. Today, it is an authoritative organ that interfaces with institutions to promote the quality of science teaching in Italy and the exploitation of the best teaching practices. Periodically, the association organises conferences aimed particularly at teachers and publishes information about its activities through reports, newsletters and its website, which contains a wealth of information organised in various sections. One of these sections is dedicated to the history of science[36] and its use in teaching, in the belief that many topics in the natural sciences can be effectively addressed in the classroom through the historical approach and that the history of science is of great educational value 'since it makes clear how provisional the scientific models that man has created over the years are and points out the intersections that have always existed between science and other fields of knowledge'. Additionally, it 'makes it possible to define course outlines, presenting material in a progression mirroring that which occurred in history'. It is possible to download hypertexts containing syllabuses in the natural sciences.

To make explicit ANISN's contribution to the debate on scientific training at school, we would like to cite here the report *La visione della scienza costruita nella scuola/The Vision of Science Created at School* (ANISN 2007).[37] The report is the result of a study which revealed an alarming situation in the scientific disciplines: the way students learn these disciplines at school distances them from science since it does not make its meaning and importance explicit, but, on the contrary, they are presented in an authoritarian, difficult, boring, selective form, too specifically aimed at the mechanical application of strategies for the resolution of problems. The only exception seems to be the natural sciences, which are more able than others to explain their cognitive role in young people's education.

SCI-DDC

The *Società Chimica Italiana – Divisione di didattica della chimica/Italian Chemical Society – Chemistry Teaching Division* (SCI-DDC)[38] is pursuing a project to include historical-teaching modules in the core university curriculum of the undergraduate programme in chemical sciences. The experimental phase of the programme was carried out in the 2007–2008 academic year at the University of Basilicata. During the following year, the pilot course ('chemistry and its evolution') was taught at the University of Camerino with the participation of university and high school teachers and students in the province of Macerata. The topics covered in the pilot programme were the development of electrochemistry, nuclear chemistry, organic chemistry, inorganic chemistry, toxicology and physical chemistry and

[37] This is a study on the perception of mathematics, physics, chemistry and natural sciences carried out through the administration of a questionnaire to 1,488 senior high school students in Italy.

[38] http://www.didichim.org/node/61

discussions with the students about the effectiveness of the historical approach to teaching chemistry. The initiative is an integral part of the Project Piano Lauree Scientifiche/Scientific Degree Project[39] in chemistry.

This proposal stems from the belief that the illustration of the historical depth of chemistry can notably improve the effectiveness of its teaching by showing where its concepts and practices come from and what their value is in terms of the work, organisation, time and passion of scientists in this field and critically focusing students' attention on concepts considered to be fully understood but which, instead, are unresolved.

The modules, taught by experts in history and the teaching of chemistry and science, are preceded by an introductory session on the historiography of the scientific disciplines and elements of the epistemology of the sciences. The subject matter modules are conducted as lessons logically inserted into the programme of host courses. The list of introductory lessons and subject matter modules is rich and varied. The former range from the epistemology of experimental cognitive science procedures to the historiography of science and chemistry. The latter illustrate the basic conceptual core of the subject, while taking an in-depth look at its historical development as related to the history of scientists and the social context of the scientific research.

Universities interested in this programme can sign up for a cycle of historical-teaching modules to be used on their campus.[40]

AIF

The activities of the AIF (*Associazione per l'Insegnamento della Fisica/Association for the Teaching of Physics*)[41] are also worthy of note. The AIF is a teacher's association founded in 1962 in Turin with the goal of popularising and promoting research in physics and the teaching of physics at all levels of school, from elementary school through to university. The association publishes and distributes scientific and teaching publications, organises teacher-training courses and conferences recognised by the MIUR (the Ministry of University Instruction and Research) and organises annual student competitions in physics. It is one of the implementing bodies (together with ANISN, SCI-DDC, the Leonardo da Vinci National Museum of Sciences and Technology Foundation in Milan and the City of Science in Naples) of the ISS (Insegnare Scienze Sperimentali/Teach Experimental Sciences) programme designed to monitor and carry out training initiatives for teachers in service under the form of research action for the improvement of the teaching-learning of the experimental sciences, with particular attention to teaching methodology.[42]

---

[40] The complete list of modules can be found at http://www.didichim.org/download/Moduli%20storico%20didattici%20AA%202009-2010.pdf.

[41] http://www.aif.it/

[42] http://archivio.pubblica.istruzione.it/argomenti/gst/iss.shtml

The association is organised in work groups: the history of physics work group,[43] founded in 1985, studies issues regarding the history of physics in terms of their teaching value. Part of the group's work includes the organisation of a winter teacher-training school with the collaboration of experts in the field, a seminar on the history of physics at the national AIF conference, refresher courses for teachers in the history and teaching of physics. The goal of the initiatives for teachers regarding history is, first of all, to help them to reflect critically on the historical developments in the field of physics, to point out the interactions between the various scientific disciplines and to promote the value of teaching the history of physics within a general physics course through the possibility of increasing historical knowledge about the development of physics theories. Furthermore, they aim to recognise and enhance the cultural and social value of science in its historical dimension, analyse the characteristics of historical research, reflect on the sources and social and cultural context of reference, improve knowledge of primary and secondary sources and analyse the available teaching materials.

64.3 Conclusion

Despite the excellent quality of the projects, research and the practical experiences carried out in Europe and Italy, a series of criticisms must be reported:

(a) The European and Italian documents that we have mentioned do not always clearly insist on the use of the history of science. Rather, they call expressly for a study of the IBSE or PBL scientific disciplines.
(b) Even where the document is explicit, this does not automatically translate into curricular content, given the 'indicative' nature of said documents.
(c) The same thing happens with academic research or field experiences: they are not included in the formal programming of teaching in the schools. This is due to the lack of a connection between universities, teacher associations and ministries for public instruction. In fact, most of the time research and field experiences do not involve those responsible for didactic policy and programming on the national level. Nor do the didactic materials produced in these studies have a level of formalisation high enough for their inclusion in formal curricular programming.
(d) While the introduction of HPS in teaching aims to combine knowledge and interdisciplinarity, in most cases teachers show a natural reticence to abandon their mono-disciplinary structure. Planning multi- or interdisciplinary teaching units requires the collaboration of other teachers who must dedicate a certain number of hours to this type of planning; these hours are currently not included in the school organisation. Additionally, the materials produced in the practical experience of carrying out interdisciplinary units, even if published, remain outside the circuit of manuals and textbooks. It is well known that 90 % of teachers' scholastic programming is based on the latter.

---

[43] http://www.lfns.it/STORIA/

Overcoming the difficulties listed here would require:

(1) A closer relationship between academic research, field experiences and instructional policies, involving the appropriate authorities as early on as in the planning of the research programmes.
(2) A high level of formalisation and promulgation of the teaching materials and learning units produced during the research and experimentation which would allow for their adoption in obligatory formal instruction.
(3) In any case, many studies have shown that modifying the curriculum is not very effective unless the teachers are motivated: 'It may be much more important to give teachers new frameworks for understanding what to count as learning than it is to give them new activities or curricula' (Langer and Applebee 1987, p. 87).
(4) The creation of institutional spaces in faculty meetings, specifically aimed at the planning of interdisciplinary courses.

Liborio Dibattista is a physician with a specialisation in hygiene. He also holds a master's degree in philosophy from the faculty of humanities and philosophy at Università degli Studi of Bari and a Ph.D. in the history of science. He has been lecturing history of science courses on history of biology and medicine at the faculty of humanities and philosophy – Università degli Studi di Bari – since 1997. He is professor of the history of science and technique at Scuola Interateneo di Specializzazione per la Formazione degli Insegnanti di Scuola Secondaria (University Specialisation Course for High School Teachers' Training). He currently works as university professor of history of medicine for high-level philosophy courses at Università degli Studi of Bari.

His research interests include the history of neurophysiology, with special attention to the mind-body problem. From a methodological point of view, Dibattista proposes an original model of scientific investigation of the historiographical texts based on computational linguistics. He is involved in promoting the teaching of science based on the history of science and, therefore, in a humanistic vision of training. He is a member of the History of Science Society, of Società Italiana di Storia della Scienza and of Società Italiana di Storia della Medicina. He is scientific director of a number of experimental projects for the application of history and philosophy of science to science education and teacher training in Italy.

He is the author of several contributions to journals in the history of science and computational linguistics and the following monographs: *Storia della Scienza e didattica delle discipline scientifiche* (Armando, Roma 2004), *J.-M. Charcot e la lingua della neurologia* (Cacucci, Bari 2003) and *Il Movimento Immobile. La fisiologia di E.J. Marey e C.E. François-Franck* (Olschki, Firenze, 2010). He is editor of *Gli Spaghetti di Mendel. Lezioni di Storia della Scienza per i Licei* (Cacucci, Bari 2008) and of *Storia della Scienza e Linguistica Computazionale. Sconfinamenti possibili* (FrancoAngeli, Milano 2009).

Francesca Morgese holds a master's degree in humanities from the faculty of humanities and philosophy at Università degli Studi 'Aldo Moro' of Bari and a Ph.D. in history of science; she is a connoisseur on history of science since 2009. She teaches classics in senior high schools.

Her research activities concern these following themes: European and Italian history of education and history of science education, the application of historical narrative in science learning, the relationship between science and the humanities and science communication in school. She is an experienced teacher in several projects PON-FSE of narrative practices and history of science in secondary schools. She has participated with scientific communications at several national and international conferences with papers on the history of medicine and the teaching of science. She is legal representative of the Scienz@ppeal Association of Bari and responsible for projects of dissemination of scientific culture in which there is communication between educational agencies and educational and research institutions of Apulia, first schools and university. She is a member of Società Italiana di Storia della Scienza (SISS).

Her main publication on teaching of science and science education is Morgese F. and Vinci V. (Eds), *Performascienza. Laboratori teatrali di storia della scienza a scuola* (FrancoAngeli, Milano 2010), and several other contributions in the field have appeared in edited books and journals.

Chapter 65
History in Bosnia and Herzegovina Physics Textbooks for Primary School: Historical Accuracy and Cognitive Adequacy

Josip Slisko and Zalkida Hadzibegovic

65.1 Introduction

Although the destiny of contemporary societies highly depends on sciences, the students' interest in becoming professional scientists is in alarming decline (Osborne et al. 2003). In Germany, for instance, the number of high school students who are interested in studying physics is significantly lower than the number of students that would like to spend their lives doing math, geography, art, and even politics (Hannover and Kessels 2004).

It is circular reasoning to say that for those students who somehow fell in love with physics, the science is always their first priority, being both most interesting and everywhere present. However, if one is looking for more convincing personal and social reasons why students have negative attitudes towards physics and science, then the answers point at the quality of their prior education and their interest in the subject (Mamlok-Naaman 2011), the academic plans (Crawley and Black 1992), the authenticity of science experiences in science education (Eijck and Roth 2009), the preferences of each student by nature or by the influence of teachers and/or parents, and even how they view scientists (Lee 1998). Recently, there were a few very informative review articles of the research literature related to the factors that affect positively or negatively students' attitudes towards science (Osborne et al. 2003; Krapp and Prenzel 2011).

M.R. Matthews (ed.), *International Handbook of Research in History, Philosophy and Science Teaching*, DOI 10.1007/978-94-007-7654-8_65,

From these studies and their theoretical frameworks, one can conclude that the proper way to make physics and science intellectually and emotionally more attractive to young people is to choose a proper mix of teaching goals and methodology, along with an adequate usage of textbooks and other supporting materials. In other words, the learning goals, the content of textbooks, and the way physics is taught should play an important role in changing the negative attitude of a large number of students toward physics and the learning of physics. Nevertheless, one must always keep in mind that the process of building students' motivations, from a psychological point of view, is a rather complex theoretical and experimental issue (Lavigne and Vallerand 2010).

For some decades, science and physics educators (Klopfer 1969; Russell 1981; Matthews 1994/2014; Irwin 2000) have given multiple arguments why positive change in attitude towards science might be achieved by increasing the presence of history of science in physics education, especially in the content of textbooks and learning tasks. It was known that historical information might help to predict students' conceptual difficulties, with similar meaning to both the students and the earlier scientists (Wandersee 1986), and to design adequate learning sequences (Monk and Osborne 1997). The strength of these arguments was increased by the results of classroom-based studies (Klopfer and Cooley 1963; Solomon et al. 1992; Solbes and Traver 2003).

For changing students' views of science and scientists, it is convenient to use original materials from the history of science contained in books, museum collections about famous physicists, and multimedia materials based on the history of science. Unfortunately, the traditional (and frequently, superficial) way of using the history of science in science teaching and learning has typically involved brief biographical sketches of scientists, fragmented notes on inventions, and photos or drawings of scientists and their works, all mainly serving a decorative role.

The contribution of the history of science to science teaching and learning began in the second half of the twentieth century, both by historical studies whose results might be useful in teaching (Conant 1957) and by physics textbooks which had a strong historical flavor (Holton 1952). The culmination of that initial interaction between history and physics teaching was the Harvard Project Physics (Rutherford et al. 1970; Holton 2003). In the course textbook, historical episodes and information were not presented continuously but at places where they might foster learning and positive attitude towards science. Regarding the use of science history in teaching and learning school science, one can find now a great variety of considerations, didactical proposals, and experimental results that are very promising (Kokkotas et al. 2010).

Teaching that makes use of historical knowledge for designing learning tasks and cares about their real implementations produces good results related, for example, to the nature of science (Abd-El-Khalick and Lederman 2000; Galili and Hazan 2001; Abd-El-Khalick 2002), attitudes towards science (Mamlok-Naaman et al. 2005), conceptual learning in optics (Galili and Hazan 2000), or notion of experimentation styles in electrostatics (Heering 2000). In general, any use of historically oriented material in science and physics courses should be carefully analyzed in a broader perspective, determined by cognitive, metacognitive, and emotional aims of physics education (Seroglou and Koumaras 2001). History of science is also useful in better articulation of teaching (Binnie 2001; Wang and Marsh 2002) and prospective teachers' education (Riess 2000).

A main issue for textbook authors and analysts is the quantity and form of historical aspects in physics that will be included in a textbook. Laurinda Leite (2002) proposed a useful model for potential authors or educators who want to use historical episodes in their classes. According to that model, textbook analysis should discover how the history of physics is incorporated into the textbook body, including (1) variety, way, organization, and usage of historical information as one group of analysis elements and (2) accuracy of historical information, context in which the historical information appear, textbook consistency, connection between learning activity, and history of physics and references as other groups of analysis elements. The chosen historical episodes could be set out in a context useful for all learners (compulsory part) and additionally in parts reserved for only those who want to know more or, in other words, for talented pupils.

The methodology of using episodes from the history of science in physics textbooks should be based on four basic requirements:

1. Historical accuracy (use of historical episodes according to original articles, letters, notes, and patents constructed by scientists, as authentic historical documents)
2. Cognitive adequacy (concordance of the episode content with the taught topic and desired cognitive skills of pupils)
3. Motivational potential (potential of the historical information to increase pupils' interest in physics)
4. Didactical tools for the learning of the chosen content that are included in science curriculum

65.2 Characteristics of Primary School Physics Textbooks in Bosnia and Herzegovina

65.2.1 General Information on Analyzed Textbooks and Their Use of History

Before recent curriculum and policy changes (introducing 9 years long primary schooling), primary school education in Bosnia and Herzegovina was carried out in eight grades (corresponding to pupils' ages between six or seven years and 14 or 15 years). Due to the specific administrative organization, there are 13 different curricula in Bosnia and Herzegovina brought by 13 regional ministries of education (two at entity level, one at district level, and 10 at canton/county level). However, one can suppose that there are no limitations and restrictions for the authors in relation to the different curricula when organizing textbooks.

Among many physics textbooks used in different regions of Bosnia and Herzegovina, we analyzed only those written by domestic authors or published by

Table 65.1 Basic data on analyzed textbooks

Author	Textbook title	Year of publication	Total number of pages	Acronym
Esad Kulenovic	Physics for 7th grade of primary school	2006	197	A7
Esad Kulenovic	Physics for 8th grade of primary school	2006	214	A8
Nada Gabela, Hasnija Muratovic	Physics VII for 7th grade of primary school	2004	132	B7
Nada Gabela, Hasnija Muratovic	Physics VIII for 8th grade of primary school	2004	116	B8
Aziza Skoko, Kasim Imamovic	Physics 7 Textbook for 7th grade of primary school	2005	202	C7
Aziza Skoko, Kasim Imamovic	Physics 8 Textbook for 8th grade of primary school	2004	180	C8
Hedija Boskailo-Sikalo	Physics 7 Textbook for 7th grade of primary school	2004	205	D7
Hedija Boskailo-Sikalo	Physics 8 Textbook for 8th grade of primary school	2005	151	D8

domestic publishers. We carried out an analysis of four textbooks for 7th grade and four textbooks for 8th grade pupils used in primary school curricula in one of the Bosnia and Herzegovina entities – the Federation of Bosnia and Herzegovina (leaving out the physics textbooks in Republika Srpska) in the school year 2010/2011. Basic information about the analyzed textbooks is given in Table 65.1.

Textbooks A7 and A8, authored by Kulenovic, are now in their sixth edition. Textbooks B7 and B8, written by Gabela and Muratovic, are now in their second edition. The remaining four textbooks C7, C8, D7, and D8 are in their first edition.

It is important to stress that the primary school physical science syllabus in BiH does not explicitly require the usage of historical content to support physics learning. The presence of such information depends exclusively on authors' and editors' decisions.

Therefore, it is not surprising that textbook authors used various forms and amounts of historical elements. A quantitative analysis of textbooks, following the checklist by Laurinda Leite (2002), revealed a total of 15 different ways of using historical episodes of physics. These ways are presented in Table 65.2.

The largest number of historical elements was found in the C8 and C7 textbooks (25 % and 21.5 %, respectively). Notes about scientists had mostly a decorative role. Heterogeneity of historical information was noticed in textbooks C and D, whose authors belong to a younger generation of authors.

Table 65.2 Total number of contents in the textbooks for the seventh and eighth grade that take into account the criteria established in the checklist

	Count by grade level		
Historical content/information	7th	8th	Sum
Independent sections on the history of physics in some chapters	6	5	11
Historical notes integrated in the text	50	52	102
Note on the name of the units under the name of the scientist	11	9	20
Short biographical sketches of scientists (up to three lines of text)	17	43	60
Longer biographical sketch of the scientist	28	50	78
Scientists' pictures or drawings	47	65	112
Prominent scientific contribution (discovery, theory, law…)	43	26	69
Original documents/texts	13	1	14
Photograph or drawing of the invention or the experiments	12	19	31
Photograph of laboratory	3	5	8
Painting of historical episodes	5	3	8
Comical drawings of historical episodes	5	0	5
Legends as supposedly historical episodes	6	1	7
Other representations of historical episodes (stamps, banknotes…)	0	5	5
Historical episodes for those who want to know more	0	1	1
Overall historical content used	246	285	531

The most frequent historical elements were in a pictorial form integrated into the body text. Only one author gave references for such depictions. Notes, photos, and drawings of the same scientists (Galileo, Newton, Tesla, and Einstein) were present in the total sample of the analyzed textbooks. Historical information was generally intended to be used by all the pupils, whereas only one author planned to use historical data in a particular section titled "If you want to know more" (textbook A8).

Talented pupils could benefit from historical information that could lead to the formation of an idea, designing and carrying out an experiment, and formulating and applying a law or a theory. There were no instructions on how to obtain additional information about famous scientists, most influential experiments, theories, or original text, although such an information is relatively easy to be found today due to the Internet.

The comparison of the textbooks in relation to their inner consistency of historical elements showed that textbooks A and B are homogeneous, whereas C and D are heterogeneous in their presentations. Only textbook D provides references related to the materials used during their preparation. This can be seen as a generation difference because younger authors use more historical elements and materials.

Although there are important differences in the amount and type of historical episodes, the use of history of physics is generally reduced to superficial biographical notes that do not introduce pupils to the process of knowledge production in physics. Representation of the historical contents used in the analyzed textbooks in terms of percentages is given graphically in Fig. 65.1.

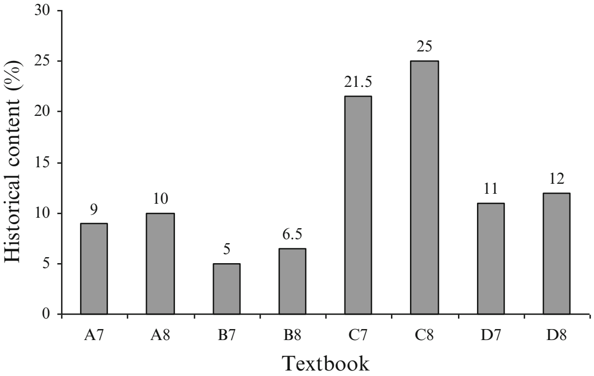

Fig. 65.1 Percentages of the overall content on history of science by analyzed textbooks

According to Fig. 65.1, it can seen that textbooks C7 and C8 contained remarkably higher amount of historical content compared to others, whereas textbook B7 had the smallest amount of historical content.

65.2.2 *Some Specific Examples of History Usage in the Analyzed Textbooks*

The elements of the history of science in the eight textbooks are used in a rather fragmented and superficial way. Mostly, they are biographical short texts describing the roles of physicists or of their inventions in very general terms. Frequently, texts are accompanied by physicists' pictures or other types of visual representation data, such as drawings, paintings, stamps, and banknotes.

The most important finding is that there are no explicit and meaningful learning tasks based on the history of science in these textbooks. The following presentation of the elements that appear most frequently will serve as an illustration of these not-for-learning-science uses of the history of physics in analyzed textbooks.

65.2.2.1 Biographical Portraits of Scientists

Sixty (11 %) short biographical sketches of scientists (up to three lines of text) have been counted. Basically, they provide the following information: birth and death year, nationality or country of origin, and the domain in which the scientist contributed by invention, law, or theory. Pictures or drawings that can be easily found on the Internet often accompany them.

Biographical information about scientists is usually included in a special position in the textbook page and always within a covered theme that is associated with the work of the scientists. There were three basic forms of presenting the life of physicists. The first is used in 32 % of the biographical notes, where scientists are presented in only one sentence associated with a picture or a drawing situated in a separate box containing a minimal amount of information: name and surname of the scientist, birth and death year, nationality or citizenship, and belonging to a scientific discipline (a physicist, astronomer, mathematician, chemist, or philosopher).

In the second form, textbook authors provide biographical notes about scientists ranging between two and five sentences (11 %), adding together data about their discoveries or inventions, or about their importance for civilization. In the third form, more informative data about scientists (57 %) are presented such as some short stories from their lives and works, ranging from 200 to 450 words. Such biographical stories about Newton, Galileo, Tesla, and Franklin can be found in the textbooks written by Skoko and Imamovic and by Boskailo-Sikalo.

65.2.2.2 Notes on Eponymous Names of Fundamental or Derivative Physical Units

In many instances, the history of science is used to inform about the origin of the names of units. From a total of 20 examples, the following two examples are presented (Boxes 65.1 and 65.2):

Box 65.1 The Origin of the Unit Name "watt" (D7, p. 150)

The unit of power is named the watt. Its symbol is W. This name was given in honor of the engineer Watt.

Box 65.2 The Origin of the Unit Name "coulomb" (B8, p. 9)

In the international system (SI) the unit of electric charge is the coulomb (symbol C). The unit is named after the French physicist Charles Coulomb who discovered the law of interaction of charges.

However, there was no information regarding neither the units that were used before the introduction of the International System of Units (SI) nor the reasons for introducing these new units. That curricular stand might be understood for those former units, like gauss, which are mainly out of use today. Nevertheless, some information about the usage of the mile, mile/hour, inch, or Fahrenheit degree as matter-of-fact units in some parts of the world (England, the USA) might be in place because students live and act in a globally connected world. This omission causes difficulties on students' understanding of Internet information and, further, could cause problems in their intercultural identification and recognition.

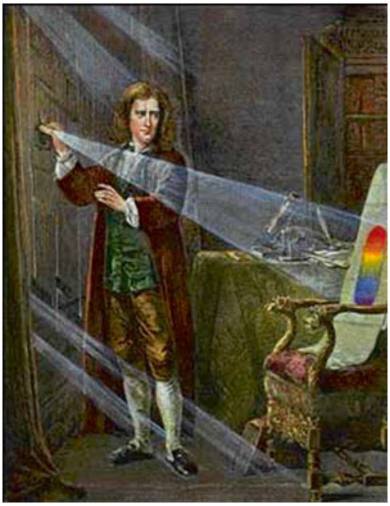

Fig. 65.2 Visual representation of Newton's famous prism experiment (D8, p. 149)

65.2.2.3 Short Historical Information About Experiments

Some important physics experiments, like Newton's prism experiment, are presented as a sentence-long information accompanying a picture (Fig. 65.2).

The text under this picture reads:

> Newton got a color spectrum by passing white light through a glass prism.

The picture used in the text is identical to the one available on-line at http://www.biographyonline.net/scientists/isaac-newton.html (accessed 10 November 2012).

This information is useless for the students' learning of the nature of light since Newton's main contribution was not the color spectrum but demonstrating via many cleverly designed experiments that the Aristotelian theory of light was wrong.

65.2.2.4 "Legendary History" of Physics

The "legendary history" of Physics is also presented in the analyzed textbooks. The following is one common example about Galileo and the Leaning Tower (Fig. 65.3):

> According to the legend, Galileo Galilei tried to calculate free fall time, observing a body falling from the Leaning Tower of Pisa. At that epoch, the time could not be calculated precisely as it happens nowadays with chronometers. Something like that was impossible. He discovered the law of uniformly accelerated motion by letting the ball rolling down an inclined plane as we indicated earlier. (C7, p. 102)

Fig. 65.3 The Leaning Tower of Pisa and Cathedral (C7, p.102) Available at URL: http://www.7wonders.org/europe/italy/pisa/leaning-tower/ (accessed 10 November 2012)

In this extract the authors incorrectly describe both the legend and the real experiment carried out by Galilei. The legend says that Galilei disapproved Aristotle's idea that "heavier bodies fall faster" by dropping two cannon balls of different weight, which hit the ground at the same time. So, "calculation of time" is not part of the legend.

Galilei's "inclined plane experiment" (Galilei 1954) was a highly discussed theme in the history of science. Repeating Mersenne's critique, Koyre (1968) claimed that Galilei neither carried out this experiment nor other experiments he described in his published books. Nevertheless, thanks to Drake's ground-breaking investigations of Galilei's handwritten notes (Drake 1973, 1975), it is now generally believed that Galilei did actually carry out his experiments.

Taking into account Galilei's description of the theory that became the basis for the "inclined plane experiment" (Galilei 1954), it is necessary to stress that Galilei didn't design that experiment to discover the law of uniformly accelerated motion, as it is claimed in the text above, but to check out if that motion is a motion with constant acceleration. For such a motion, Galilei knew the theoretical relation between distance covered and time elapsed: the covered distance is directly proportional to the square of time elapsed.

Galilei's worldview led him to believe in such a possibility for free fall, and he wanted to have experimental evidence. He repeated the experiment increasing progressively the inclinations. The data he got were the expected ones according to the theoretical model (distance covered directly proportional to the time squared). This made him to infer that very likely free fall (motion down the plane with 90° inclination) is also a uniformly accelerated motion.

Even more erroneous treatment of Galilei's "thought experiment" regarding the logical possibility of forceless motion has been found in the analyzed textbooks. This thought experiment was given in the form of Socratic conversation between Salviati and Simplicio in "Dialogue concerning the two chief world systems" (Galilei 1967). Salviati led Simplicio to accept that (a) a ball rolling down an inclined plan increases its speed; (b) the same ball rolling up an inclined plane decreases its speed. After that Salviati formulated a very disturbing question for Simplicio (a person advocating the Aristotelian view of motion):

> Now tell me what would happen to the same movable body placed upon a surface with no slope upward or downward. (Galilei 1967, p. 147)

Two different treatments of this "thought experiment" by Galilei are presented below. The first example is extracted from the A7 textbook and the second from the D7 one (Boxes 65.3 and 65.4). The illustration showed in Fig. 65.4 is one similar to the A7 and D7 illustrations:

Box 65.3 Textual Description of the Experiment (A7, pp. 93–94)

When a small ball is rolling down an inclined plane of a certain height, it will continue to move uniformly in a horizontal surface, and then climb up another inclined plane to the same height from which it started. In the absence of friction, this climbing will be independent of the distance traveled horizontally and the slope of the inclined plane along which the ball climbs. On this basis, Galileo concluded that the body moving at a certain speed on a horizontal surface in the absence of friction and other resistant forces will continue to move uniformly forever. This conclusion is known as Galilei's principle of inertia.

Box 65.4 Textual Description of the Experiment (D7, p. 121)

Galileo Galilei observed the movement of the ball rolling down a double inclined plane in which the slope of the right part can be changed. If we reduce the slope of the right inclined part, and the ball rolls down from the same position, then the ball rolls up the right inclined part to the same height but the distance it must go along the slope is greater. The maximum distance is achieved when the ball moves in a horizontal surface at the right side.

Every body persists in its state of rest or uniform motion in a straight line unless it is compelled to change that state by forces impressed on it.

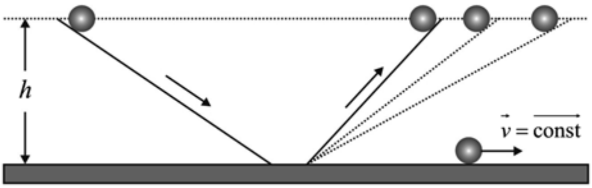

Fig. 65.4 An illustration of Galilei's "thought experiment" on inertial motion (A7, p. 94, and D7, p. 121)

> We describe Galilei's experiment and his conclusion…(A7, p. 93)

As it can be seen, both treatments erroneously suggest that this "thought experiment" was a real experiment, carried out by Galilei.

Erroneous and superficially simplified presentations of physics history in textbooks, especially of those important episodes that are connected to research-based historical facts, are not an exotic syndrome of the authors from Bosnia and Herzegovina. On the contrary, it is a rather global phenomenon, as recent Niaz's books (2008, 2009, 2010) show convincingly. This unsatisfactory situation is caused, on the one hand, by the weak quality control in physics teaching and textbook writing (Slisko and Hadzibegovic 2011), which makes possible the invention of (erroneous) historical information due to the ignorance of the authors, reviewers, and users. This invented information enters and stays in the textbooks. On the other hand, there is an inclination of the research community towards the "backwards written history," which is common in the way "normal science" is presented in physics textbooks (Brackenridge 1989).

Backwards written history refers to special classes of falsified history in which historical episodes are presented in a way that leaves the impression that modern concepts and procedures were used when, in fact, they didn't exist in that particular time. So, it is not a physics history as it really was, but a physics history as it might have been but was not. One paradigmatic example of *backwards written history* is the known (erroneous) claim in the physics textbooks that Cavendish measured the value of the gravitational constant, although his research question and reasons were different, and the very idea of the gravitational constant did not yet exist (Slisko and Hadzibegovic 2011). A misleading interpretation of the Greek atomism as an anticipation of the modern scientific atomic theory is also common in philosophical literature (Chalmers 2009).

Among 531 examples of use of historical information detected in the analyzed physics textbooks for primary school in Bosnia and Herzegovina (BiH), one example was chosen, found in the D8 textbook, to explore how primary school students (pupils) make sense of superficial and incomplete presentations of an historical episode. Up to date, this is the first study of this kind related to the uses of history in BiH physics textbooks.

Our objective is to show by some initial data that such presentations are not cognitively adequate for pupils. Namely, the pupils as sense-making persons try to provide the missing information to establish the story coherence. This process, as it will be shown later, is potentially damaging for the pupils' learning because the missing information they provide may take forms that neither correspond to the historical facts nor is physically possible.

65.3 Chosen Historical Episode for Research with Primary School Students: The Measurement of the Speed of Sound in Water

The chosen historical episode is the measurement of the speed of sound in water, carried out by Jean-Daniel Colladon in 1826 at Lake Geneva (Colladon 1893). That measurement was very important for checking whether the theoretical formula for the speed of sound in combination with the measured value of the water

Fig. 65.5 The boat with underwater bell and mechanism for sending light signal

compressibility would predict a correct value of the speed of sound in water. That research was planned and successfully accomplished by Colladon and Sturm. For that particular research they received the first award of the French Academy of Science. Although these contextual details would be very important in analyzing textbook presentations of the Lake Geneva Experiment at higher educational levels, we will not deal with them in the analyzed accounts for younger students (grade VIII in Bosnia and Herzegovina and grade IX in the UK).

65.3.1 Design and Results of the Original Experiment

The basic ideas of the experiment design at Lake Geneva were as follows: An assistant of Colladon (Sturm was then in Paris and did not take part in the experiment!), being in one boat, sent simultaneously an underwater sound signal and a light signal in air. The sound signal was produced by striking an underwater church bell with a hammer. A complicated mechanism simultaneously ignited the gunpowder and struck the bell on the first boat (Fig. 65.5).

Colladon himself was in the second boat with a long horn immersed in the water, attached to his left hand (Fig. 65.6). The immersed end of the horn had an elastic membrane that would vibrate when reached by the underwater signal, making possible for Colladon to hear the sound of the bell. He activated a chronometer (stopwatch) using his right hand when he saw the light signal coming from the first boat and stopped it when he heard the sound of the bell that came through the water.

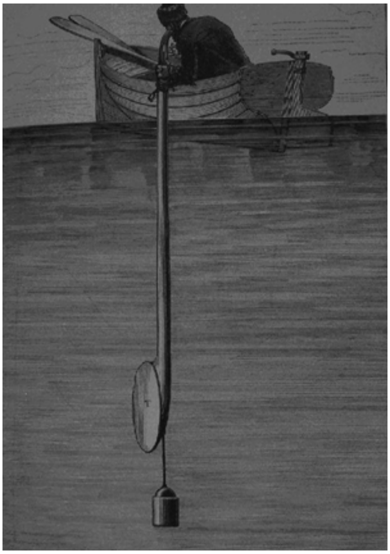

Fig. 65.6 The boat with underwater horn is used to hear the sound produced by bell

The distance between the two boats was carefully measured by triangulation methods and it was found to be 13,478 m. The mean time the sound needed to travel through water between the bell and the horn was 9.4 s. These values result in a value of 1,435 m/s for the speed of sound in water.

65.3.2 A Textbook Presentation of the Lake Geneva Experiment in Bosnia and Herzegovina

Only one textbook (D8) presented the experiment carried out by Colladon at Lake Geneva, combining verbal and visual information. The textual part is as follows:

> A physicist and his assistant were in two boats 1,500 m away from each other. A bell on a rope was immersed in the water from the first boat with the assistant in it. His task was to hit the immersed bell with a hammer and simultaneously send a light signal. The physicist with a long horn was in the second boat. One end of the horn was immersed in water, while the other end of the horn was held by the physicist near his ear. The moment he saw the light signal, the physicist switched the chronometer on and measured the difference of time between the moment he saw the light and the moment he heard the sound. The delay of the sound signal was one second. The physicist concluded that the sound needed 1 s to travel 1,500 m through water, and that the speed of sound in water was 1,500 m/s. (D8, p. 102)

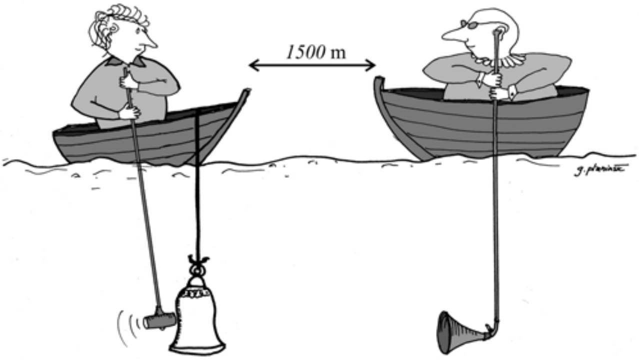

Fig. 65.7 The drawing of Colladon's experiment, similar to the picture in D8, p. 102

The visual representation of the experiment is a drawing of the situation (Fig. 65.7)

This example is analyzed from two perspectives. The first one is its historical accuracy or, in other words, whether the description of the particular episode is precise enough. It is easy to see that the author presents false experimental data, giving for distance and time the values of 1,500 m and 1 s, respectively.

The second, even more important one is the cognitive perspective: Is the presentation structured in a cognitively adequate way giving thus pupils an opportunity to learn how physics in its experimental domain works, without inducing students to accept some erroneous ideas?

Comparing verbal and visual descriptions, it is possible to detect incoherence between them, which would be a learning obstacle for all students who try to comprehend fully the way the experiment was carried out. Namely, the drawing gives students no idea of how the light signal was sent as, according to the drawing, assistant's both hands are employed to hit the underwater bell by the hammer. The other, potentially enigmatic part for students, is how the physicist can switch on and off the chronometer if, again, both of his hands are used to hold the horn under water.

So, the above textbook presentation of the historical experiment in which the speed of sound in water was measured is:

1. Historically inaccurate (the values of the distance and time are arbitrarily invented)
2. Depersonalized (Colladon became an anonymous physicist)
3. Cognitively inadequate (neither the text nor the drawing gives students an opportunity to comprehend fully how the experiment was carried out)

65.3.3 Another Textbook Presentation of the Lake Geneva Experiment

To put this particular textbook presentation in a broader international perspective, it is instructive to look at another presentation of the same experiment which comes from the UK:

> Newton's work predicted that sound should travel faster in water than in air.
>
> This was proved by an experiment on Lake Geneva in 1827. An underwater bell was rung at the same time as some gunpowder was lit. On another boat 14 km (9 miles) away, the flash was seen (at night) and the sound was heard through the water by a large ear trumpet dipping into the water (Johnson et al. 2001, p. 82, italics added).

The follow-up tasks for the students are:

1. Think about the Lake Geneva Experiment, and sketch what you think the apparatus looked like on each boat.
2. With a distance of 14 km the sound took 10 s. What was the speed of sound in water? (Johnson et al. 2001, p. 82, Question 3)

Regarding historical accuracy, the UK textbook authors present rounded values of the distance and time that are close enough to the original ones. The year of the experiment is not the correct one and corresponds to the year the results were initially published.

It is very good that the authors asked students to calculate the speed of sound in water instead of giving them its value (task b).

It is also a good idea to suggest students to sketch how the experiment was carried out (task a), although it might be a very demanding drawing task for students due to the fact that the verbal description is really incomplete and hardly can lead any student towards necessary technical details of the design (see Figs. 65.5 and 65.6). In addition, the impersonal form of the narrative about the experiment might be a serious obstacle for students' sense making and learning.

Being inspired by the drawing task (1) in the UK textbook presentation, in our research, described in the next section, we explored how students visualize and make sense of incomplete verbal and visual information of the chosen textbook presentation of the historical experiment for measuring the speed of sound in water.

To make our discussion of the process followed by the students as they try to understand a given text more understandable, it is necessary to remind readers of the ideas of Kintsch (1998) and Kintsch and van Dijk (1978) regarding text comprehension. They claim that two basic steps are important in order to understand a text: the construction of the text base and the construction of the corresponding situation model. The text base is drawn from the propositions of the text, and it expresses its semantic content, both globally and locally. The situation model is constructed by integrating the textual content in the reader's knowledge schemes. Any text for which the reader is unable to construct a correct situation model is not understandable. If the text is taken from a textbook, then such a text is not cognitively adequate for students learning.

The research procedures to find out details of the situation models students construct for a textbook presentation might be word based or drawing based. As already indicated, the second option was selected. This option is used in research on students' science learning (Benson et al. 1993; Edelson 2001; Köse 2008; Shepardson et al. 2011), students' comprehension of scientific texts (Schwamborn et al. 2010; Leopold and Leutner 2012), and students' images of scientists (Farland-Smith 2012) or mathematicians (Picker and Berry 2000).

Up to date, as far as we know, this is the first research using pupil's drawings as a tool to assess comprehension of textbook presentation.

65.4 Basic Research Description: Participating Pupils, Worksheet Design, and Evaluation

65.4.1 Participating Pupils

A group of 151 pupils participated in this research. The locations of the schools and pupils' gender characteristics are given in Table 65.3.

Locations of the PS1–PS3 were situated in Sarajevo Canton, whereas location PS4 was situated in Central Bosnia Canton. It is worthy to mention that these two Cantons were randomly selected and have different education policies.

Pupils were given text worksheets (Box 65.5) containing only written information on the Lake Geneva Experiment from the textbook D8 and four tasks. The original picture showed in the D8 textbook was not attached.

65.4.2 Worksheet Design and Evaluation

The first task was to make a drawing based on the information given in the text worksheet. The second task was to explain in textual form all the difficulties they encountered in the first task. After that, the students were given the original drawing from the D8 textbook, and they were told to complete the third and fourth task.

Table 65.3 Distribution of pupils by school, number of class unit, and gender

School	N (Classes)	Female	Male	N (Pupils)
PS1	1	11	11	22
PS2	1	13	6	19
PS3	3	22	28	50
PS4	3	30	30	60
Total	8	76	75	151

Box 65.5 The Content of the Worksheet

(WS)Pupil’s Code:

Speed of Sound in Water

The following text describes the experiment used to measure the speed of sound in water in the nineteenth century:

A physicist and his assistant were in two boats 1,500 m away from each other. A bell on a rope was immersed in water from the first boat with the assistant in it. His task was to hit the immersed bell with a hammer and simultaneously to send a light signal. The physicist with a long horn was in the second boat. One end of the horn was immersed in water, while the other end of the horn was held by the physicist near his ear. In the moment he saw the light signal, the physicist switched the chronometer on and measured the time difference between the moment he saw the light and the moment he heard the sound. The delay of sound signal was one second. The physicist concluded that the sound needed one second to travel 1,500 m through water, and that the speed of the sound in water was 1,500 m/s.

Questions/Tasks

1. Insert into the box below your own drawing according to the given text.

2. If any part of the given text is not presented in your drawing, then describe that part by your own words. Explain why it is important to understand this experiment, and why it might be difficult to draw it.
   Answer:

3. Describe your feelings and thoughts about your own drawing and the drawing from the textbook that has been shown to you.
   Answer:

4. Express your opinion here about your today learning experience.
   Answer:

The third task asked the students to give feedback on their thoughts and emotions after the presentation of the original drawing. The feedback was given verbally in a classroom in the presence of one of the researchers (Z. H.). Finally, the students were asked to complete the fourth task by expressing their attitudes towards active and passive physics learning and to compare this classroom experiment with the standard education they received previously.

The first task was used to assess the ability of pupils to construct an adequate situation model according to Kintsch's terminology.

To track pupils' achievements, a scoring scheme was developed specifically to evaluate pupil's understanding of the given text. According to this, each of the following scoring rubric elements was graded with one point (seven points in total):

1. Any drawing according to in-class reading (given text)
2. Drawing similar to the D8 (the same number and choices of drawing elements)
3. Device for sending light signal from the first boat
4. Instrument/device for time measurement placed in the second boat
5. Sound wave representation in sinusoidal shape
6. Data of distance (1,500 m)
7. Velocity value (1,500 m/s).

65.5 Results and Analysis

The statistical data based on the results of the 151 pupils who responded to the questions and solved the tasks in the WS were analyzed. Achieved scores within different groups of pupils (male or female and pupils from different cantons) were tested for normality of distribution with Kolmogorov-Smirnov and Shapiro-Wilk tests. Since the distribution was not normal, the scores were expressed as median and compared within different groups with Mann-Whitney test. Pupils reached the median value of four points.

There were no significant differences in scores between pupils from different counties (Mann-Whitney U: 2602.5, $p = 0.62$) or between male and female pupils (Mann-Whitney U: 2,740, $p = 0.68$). However, the minimum score achieved by the male pupils was 2, whereas the female pupils had a minimum score of 0 (Table 65.4).

A maximum score of seven was accomplished by five (3.3 %) pupils. Pupils were classified into five groups according to the number of achieved points as follows:

Group I: 0–3 points
Group II: 4 points
Group III: 5 points
Group IV: 6 points
Group V: 7 points.

The distribution of the pupils among the above mentioned groups is shown in Fig. 65.8.

Pupils' results that scored according to the seven expected drawing elements (items) are presented in Table 65.5.

The most important result of this research was the opportunity for each pupil to actively participate in drawing and after-drawing discussions. According to their

Table 65.4 Basic statistical data

	Male, N = 75	Female, N = 76	Total, N = 151
Median	4	4	4
Range	5	7	7
Minimum	2	0	0
Maximum	7	7	7
Achieved/total points (%)	61	62	61

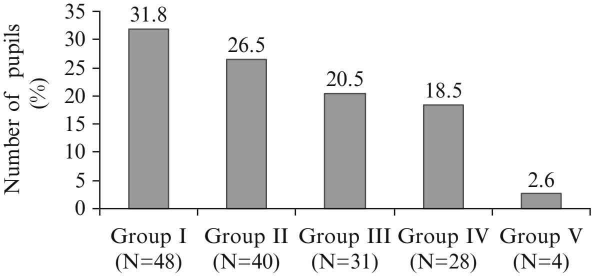

Fig. 65.8 Distribution of pupils' groups by achieved points

Table 65.5 Percentage of pupils that scored in each item

Expected drawing item	Grading point	Frequency (%)
Any drawing according to the text	1	99.3
Drawing identical to the D8	1	28.5
Device for sending light signal from the first boat	1	11.3
Instrument/device for time measurement placed in the second boat	1	15.2
Sound wave representation in sinusoidal shape	1	58.9
Data of distance (1,500 m)	1	79.5
Velocity value (1,500 m/s)	1	18.5

teachers' testimonies, many of them find common activities in physics classrooms to be boring and uninteresting because of their passive roles.

Surprisingly, the number of pupils who used sound wave representation in sinusoidal shape was high (58.9 %). This is interesting because in the primary school curriculum, they do not meet graphical representation of the sine function or analytical representation of wave phenomenon. Obviously, this is an influence from their out-of-school experiences.

Among the 151 pupils, 79.5 % considered the sound velocity value as an important detail that they needed to include in their drawings. However, it was discovered in a posterior class discussion that around 60 % of them believed that the sound velocity in air is greater than in water.

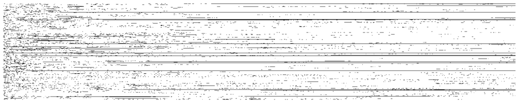

Fig. 65.9 A pupil's drawing with both light-sending and time-measuring devices

Data analysis is separated into four parts.

Part A
Basically correct drawings were given by 39 % of pupils, with *both light signal sending and time-measuring devices* being inserted into drawings that were similar to the one from the D8 (Fig. 65.9). Although their devices do not correspond to the actual devices used in the experiment, it is interesting that four out of 10 students were able to construct an adequate situation model from the given text. So, despite that some of the primary school students (from 14 to 15 years old) feel bored by the common physics learning activities, they grasped the experimental situation in a more accurate way than the artist who created the textbook drawing and the editor and reviewers who approved it!

Part B
Some pupils (11 %) revealed an abovementioned "backwards written history" approach to the reconstruction of the historical episode by drawing contemporary devices, such as lasers or digital watches. They can be hardly blamed for this "error" because that was their solution to the problem of cognitively inadequate narrative, which is unclear about the light-sending procedure or mentions time-measuring instruments that might be unknown to pupils (chronometer).

Part C
Only eight pupils (5 %) answered the second WS question. Such a poor participation can be understood within the context of classroom culture: these pupils are rarely asked to express and describe in their own words their thinking as well as the learning obstacles they encounter. This explains why it was preferred to use the drawing mode instead of the verbal mode to explore the students' comprehension of the text.

Nevertheless, what these eight pupils wrote is very informative. Five of them indicated that they did not know how to present sound after the light signal was sent. Two students wrote down that they found difficult to draw a "broken" thing (hammer, bell, horn). It is a nice example of how complex a drawing task might be for students who would like to apply their prior knowledge from optics. One student wrote that he did not know how to represent the situation of the physicist in the second boat seeing the light signal.

Part D
The students finally had the chance to observe the textbook's drawing and make comparison between the textbook's and their own drawing. This resulted to a series of different comments. According to the comments and expressed emotions, the pupils can be divided into three groups: satisfied, frustrated, and indifferent.

The first group (G1) consists of 78 satisfied students (52 %) who expressed positive emotions and gave affirmative comments after comparing their drawings with the textbook drawing shown to them by the researcher (Z. H.). The most prevalent keywords they used were "happy, satisfied, and pleased."

The second group (G2) consists of 10 frustrated pupils (7 %) who had negative comments and emotions about their drawings after the comparison with the textbook drawing. They used keywords like "disappointed, sad, frustrated, and embarrassed."

The third group (G3) consists of 63 indifferent pupils (41 %) who had no written comments or opinion presented in the WS.

In G1 four different subgroups of pupils can be distinguished who used different descriptions of their drawings as follows:

G1-a: "My drawing is *similar* to the drawing from the textbook" was stated by 61 pupils (72 %).
G1-b: "My drawing is *the same* as the drawing in the textbook" was stated by 7 pupils (8 %).
G1-c: "My drawing is *different* from the drawing in the textbook" was stated by 11 pupils (13 %).
G1-d: "My drawing is *better (richer)* than the drawing from the textbook" was stated by 4 pupils (5 %).

It is interesting to note that in the G1-a subgroup, there are pupils whose drawings include the same elements as the drawing from the textbook (case of 28 of pupils). Twenty pupils drew both signal devices, while the drawing from the textbook does not show any signal. Seven pupils used a light source (lamp, laser, sun-mirror) in their drawing, and six pupils had the time-measuring device in the boat with the physicist.

In the G1-b subgroup some pupils' drawings actually were different. Two pupils used two assistants in the boat; others drew a signaling device in the physicist's boat.

In the G3-c subgroup the pupils explicitly stated why their drawings were better or richer than the drawing from the textbook:

> My drawing is better because I have a lamp and a timepiece which is not included in the original drawing.
>
> My drawing is a better one. In the drawing from the textbook the light is not shown, the sound visualization is not found and the distance between the two boats is poorly represented.

Pupils from G2 believed that their drawings differed from the textbooks' drawing because they did not draw the physicist and his assistant (boats without people, for example). This is a very important detail, because both persons were mentioned

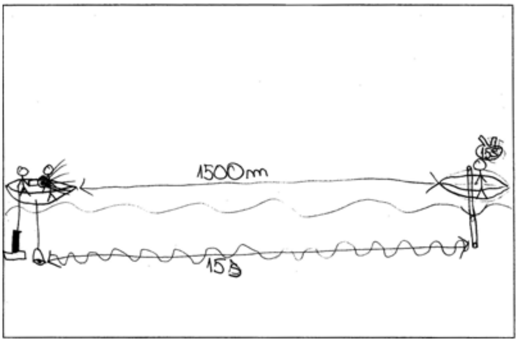

Fig. 65.10 Two experimenters in the first boat

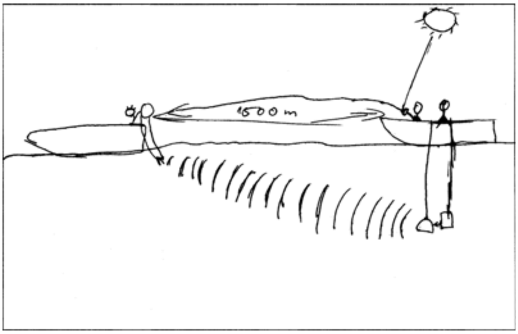

Fig. 65.11 Two experimenters in the first boat, one sending light signal by a mirror that reflects a ray from the sun

explicitly in the text. So, if some pupils omit in-text-mentioned persons in their drawings, then it is very likely that this situation model without persons will be found more frequently in pupil/student-generated drawings for the narrative given in the UK textbook (Johnson et al. 2001) that does not mention the persons who carried out the experiment.

65.5.1 Some Comments on Selected Pupils' Drawings

Pupils' sense making of the textbook verbal information about the Lake Geneva Experiment is a subtle process. It can be derived from pupils' drawings, which are their visual representations of the corresponding situation model.

In order to solve the problem how the two simultaneous events (i.e., hitting the bell and sending the light signal) were carried out, some pupils added the second experimenter in the first boat. One experimenter hits the bell and the other sends the light signal using a light source. Two different approaches were used to show the way the signal was sent. According to the first one, the signal was sent from a light source (Fig. 65.10). According to the second, the light signal consists of the solar light beam reflected by a mirror (Fig. 65.11).

A further difference appears in the second boat. Although in both cases the experimenter used the tube to receive the sound signal through the water, in the first case no

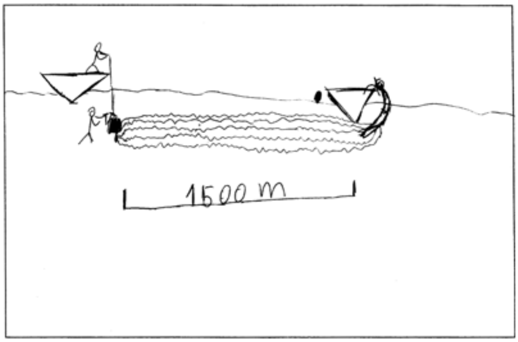

Fig. 65.12 One experimenter in the first boat and the second underwater

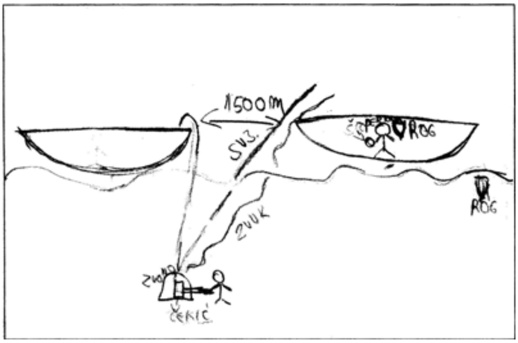

Fig. 65.13 An experimenter with two busy hands in the second boat

time-measuring device is presented, while in the second a watch is floating in the air near the experimenter. Obviously this pupil did not know the way the device operated.

Two experimenters are imagined in other drawings, too (Fig. 65.12). In the first boat one experimenter stands holding the rope with the bell, while the other experimenter is under the water hitting the bell. Obviously, for this pupil the only way to hit an underwater bell is to have somebody under the water to do it.

The same idea of hitting one underwater bell was adopted by another pupil (Fig. 65.13). Curiously, this pupil was able to imagine that the physicist in the second boat could use the right hand to hold the chronometer and the left hand to operate the tube.

Another pupil applied the two-busy-hands idea for the experimenter in the first boat (Fig. 65.14). The first experimenter uses his right hand to send the light signal from a battery lamp and the left hand to hit the underwater bell by a hammer. Interestingly, this pupil did not apply the same idea for the second experimenter who holds the tube but not the digital chronometer.

One pupil drew both experimenters with two busy hands (Fig. 65.15). The experimenter in the first boat uses one hand to hit the underwater bell and the other hand to hold a mirror to send the light signal (in the form of reflected solar rays).

The experimenter in the second boat holds with both hands the timepiece, while the tube is attached to his left ear.

The mirror as light-sending device appeared in another drawing, too (Fig. 65.16). This pupil suggested a pendulum as time-measuring device.

65.6 Conclusion

A great part of the historical information found in physics textbooks for primary school in Bosnia and Herzegovina is useless for learning about the nature of science because it is too short and rather incomplete. In the case of the Lake Geneva Experiment, a longer description of the historical episode was both historically erroneous and cognitively inadequate.

Cognitive adequacy was studied in relation to the textbook verbal description of the Lake Geneva Experiment aiming to measure the speed of sound in water. The task for the pupils was to make sense of the corresponding text by drawing the situation model concerning the specific experiment. In Kintsch's theory of text comprehension, the quality of the constructed situation model reveals the level of understanding.

Although 40 % of the pupils were able to draw an acceptable situation model with both light-sending and time-measuring devices that are absent in the textbook drawing, many pupils experienced difficulties in imagining how the experiment was done. Obviously, the text describing the experiment does not contain enough verbal clues to help these pupils construct a correct visual representation of the experimental situation. For them the textbook presentation of the experiment is incomplete and, in consequence, is not cognitively adequate.

In their sense-making efforts, some pupils suggested solutions (like underwater experimenter hitting the bell) that are erroneous. This fact shows that incomplete and superficial historical information is potentially misleading for pupils' learning.

Almost all pupils actively participated in the drawing activity, but very few provided written comments on the difficulties they experienced in thinking about how the experiment was done. The alarming absence of written pupils' notes about their thinking is very likely related to the classroom culture in which they rarely are asked to express what they think.

In the post-drawing discussion (with Z. H.), pupils commented that they enjoyed this novel activity (i.e., first draw the experimental situation and then compare their drawings with the textbook drawings) very much. It seems that most pupils prefer to talk about their ideas rather than to write about them, which is maybe a result of a rigid and more traditional education system in Bosnia and Herzegovina.

Up to date, this was the first study of the pupils' sense making of an incomplete textbook presentation of the Lake Geneva Experiment. Consequently, there are possibilities for future research. Some interesting questions are:

Would a "group drawing activity," following individual drawing attempts, improve the sense-making process of the same incomplete text?

Would a more complete verbal description of the historical episodes lead to better quality pupils' drawings?

Would impersonal account of the experiment, like the one in the UK textbook, be more difficult for pupils' drawing?

Acknowledgements We are very grateful to Prof. Gorazd Planinšič (University of Ljubljana) for his artwork in Fig. 65.7. Our thanks also go to Prof. Dewey I. Dykstra, Jr. (Boise State University), Prof. Chris Moore (Coastal Carolina University), and Dr Ioannis Papadopoulos (School of Primary Education, Aristotle University of Thessaloniki) for their kind help in improving the English.

Josip Slisko (B.Sc. in physics, M.Sc. in philosophy of physics, Ph.D. in philosophical sciences) teaches courses on physics and mathematics education at Facultad de Ciencias Físico Matemáticas of the Benemérita Universidad Autónoma de Puebla. His research interests include students' explanatory and predictive models of physical phenomena, students' strategies for solving untraditional physics and mathematics problems, presentation of knowledge in textbooks, and design of active learning sequences which promote cognitive, metacognitive, and emotional development of students. Josip Slisko is author or coauthor of 80 journal articles and 12 physics textbooks. Since 1994 he joined the Sistema Nacional de Investigadores (National System of Researchers), a program of the Mexican government through which scientific production of one is evaluated and a stipend is paid to recognized scientists. He is member of American Association of Physics Teachers and serves in editorial boards of various educational journals (Latin American Journal of Physics Education, European Journal of Physics Education, Metodicki ogledi and Eureka). Since 1993, every last week in May, he is the president of the committee that organizes an international workshop called New Trends in Physics Teaching.

Zalkida Hadzibegovic (B.Sc. in physics, M.Sc. in history and philosophy of science, Ph.D. in physics) teaches courses on general physics, astronomy, and philosophy and history of science at the University of Sarajevo, Bosnia and Herzegovina. Zalkida Hadzibegovic created and implemented a new course curriculum in the Second Bologna Study Cycle in the field of philosophy of science for prospective physics teachers and researchers and has been offering a few master work themes which will begin research related to the role of history and philosophy of science in Bosnian elementary and high school education. She established in 2009 the first science education research group (Sarajevo Chemistry and Physics Education Research Group) which conducts research on integrated chemistry, physics, mathematics, and history and philosophy of science knowledge and focused on active learning approach. Her research interests include the applications of history and philosophy of science in science education and students' scientific literacy and creativity at the university and high school level especially for talented students. Zalkida Hadzibegovic is author or coauthor of several physics textbooks. She published a few articles related to different topics of physics education participating as author or coauthor at the GIREP (Groupe International de Recherche sur l'Enseignement de la Physique/International Research Group on Physics Teaching) conferences, ESERA (European Science Education Research Association), BPU (Balkan Physical Union), and WCPE (The World Conference on Physics Education) conferences, and at the SEAC (European Society of Astronomy in Culture) conferences in the field of astronomy.

Chapter 66
One Country, Two Systems: Nature of Science Education in Mainland China and Hong Kong

Siu Ling Wong, Zhi Hong Wan, and Ka Lok Cheng

66.1 Introduction

An understanding of NOS has been widely recognised as an essential component of scientific literacy and has been included as a curriculum goal in science curriculum standards documents in many developed regions of the Western world.[1] Driver, Leach, Millar and Scott (1996) have crystallised from the literature five arguments in support of developing students' NOS understandings:

1. Utilitarian – understanding NOS is necessary for making sense of the science and managing the technological objects and processes in everyday life.
2. Democratic – understanding NOS is necessary for making sense of socioscientific issues and participation in decision-making process.
3. Cultural – understanding NOS is necessary for appreciation of science as a major element of contemporary culture.
4. Moral – understanding NOS can help develop awareness of the norms of the scientific community that embodies moral commitments which are of general value.
5. Science learning – understanding NOS can support successful learning of science content.

M.R. Matthews (ed.), *International Handbook of Research in History, Philosophy and Science Teaching*, DOI 10.1007/978-94-007-7654-8_66,

Although NOS has been one of the extensively researched areas in science education, there is not a unified way to define the term NOS in the literature. Some authors (Abd-El-Khalick and Lederman 2000; Lederman 2007) delimit NOS to aspects related to epistemology of science. In this chapter, we adopt a broader meaning of NOS in common with definitions adopted by Clough (2006), Irzik and Nola (2011), Osborne and his colleagues (2003) and Wong and Hodson (2009, 2010). The phrase NOS used in their work encompasses the nature of scientific inquiry, the nature of the scientific knowledge it generates, how scientists work as a social group and how science impacts, and is impacted by, the social context in which it is located.

Science education in both the mainland China and Hong Kong has undergone major curriculum reform since the beginning of the twenty-first century. One of the common new aims introduced in curriculum standards documents is the development of students' appreciation of nature of science (NOS).

Prompted by the soaring economy in recent years, which has brought tremendous changes in people's lives, the mainland Chinese government started to look for strategies to sustain long-term development of the country. These strategies include reforming education that can nurture and prepare the future generations for its development. Within science education in mainland China, there is a transition from a more elite to a more 'science for all' curriculum with an emphasis on the promotion of scientific literacy (Wei and Thomas 2005). NOS has hence started to become an important topic in some science curriculum reform documents (e.g. Ministry of Education [MOE] 2001a, b), Chinese academic articles,[2] as well as textbooks for training science teachers (e.g. Liu 2004; Yu 2002; Zhang 2004).

Science education in Hong Kong has also undergone considerable changes since the implementation of the revised junior secondary science curriculum (grades 7–9) (Curriculum Development Council [CDC] 1998). It was the first local science curriculum that embraced certain NOS features, e.g. being 'able to appreciate and understand the evolutionary nature of scientific knowledge' (CDC 1998, p. 3) was stated as one of its broad curriculum aims. In the first topic, 'What is science?', teachers are expected to discuss with students some features about science, e.g. its scope and limitations and some typical features about scientific investigations, e.g. fair testing, control of variables, predictions, hypothesis, inferences and conclusions. Such an emphasis on NOS was reinforced in the revised secondary 4 and 5 (grades 10 and 11) physics, chemistry and biology curricula (CDC 2002). Scientific investigation continued to be an important component, while the scope of NOS was slightly extended to include recognition of the usefulness and limitations of science as well as the interactions between science, technology and society (STS). In the recently implemented senior secondary curricula of the science subjects (CDC-HKEAA 2007), there is a further leap forward along the direction of earlier curriculum reforms in the curriculum and assessment guides. The importance of

---

[2] See, for example, Chen and Pang (2005), Liang (2007), Xiang (2002), and Yuan (2009).

promoting students' understanding of NOS is explicitly spelt out together with its perceived benefits to students.

Although understanding of NOS has become a key curriculum aim in the science curriculums in both mainland China and Hong Kong, under the policy of the 'One Country, Two Systems', Hong Kong has retained its autonomy to decide on its own policies. There have been some distinctive differences of NOS education in both places as reflected in the (1) official curriculums, (2) textbooks, (3) teacher training and (4) school teachers' implementation of NOS teaching. This chapter provides an overview of the situations about NOS education in both places for these four areas.

66.2 NOS as Portrayed in Official Science Curricula

In a recent study, Cheng and Wong (in print) have examined the NOS ideas included in the two recent official senior physics curriculum documents used in mainland China (MOE 2004, thereafter known as '*CHN-Standards*') and Hong Kong (CDC-HKEAA 2007, '*HK-Guide*'). Ten NOS ideas are identified as listed below:

1. Laws as generalisations and theories as explanations of the generalisations
2. Creative elements of the scientific processes
3. Tentative and developmental nature of science
4. Distinction and relationship between science and technology
5. Theory-laden nature of scientific processes
6. Empirical nature of scientific knowledge
7. Different ways of performing scientific investigations
8. Interactions between science, technology and the society
9. Moral and ethical dimensions of science
10. Scientists as a community

Among them, some are similarly represented in both Hong Kong and the mainland China, including 'Laws as generalisations and theories as explanations of the generalisations', 'Tentative and developmental nature of science', 'Empirical nature of scientific knowledge' and 'Scientists as a community'. However, some of these NOS ideas, including 'Different ways of performing scientific investigations', 'Interactions between science, technology and the society' and 'Moral and ethical dimensions of science', are presented with significant differences.

66.2.1 Methods of Scientific Investigations

There is a dedicated chapter on scientific investigations in *CHN-Standards* in which the 'components of scientific investigations' are listed in a table as shown in Table 66.1. The seven components are stunningly similar to *the* stepwise scientific method as one of the myths about NOS highlighted by McComas (1998).

Table 66.1 Components of scientific investigations as presented in *CHN-Standards* (pp. 10–11)

Components of scientific investigations	Basic skill requirements for scientific inquiries and physics experiments
Question formulation	Able to discover physics-related problems Express these problems clearly as physics problems Aware of the significance of problem discovery and question formulation
Speculation and hypothesis formation	Propose problem-solving methods and solutions to problems Predict the results of physics experiments Aware of the importance of speculation and hypothesis
Experiment planning and design	Develop plan according to the experimental objectives and conditions Attempt to select the appropriate experimental methods, set-ups and instruments Consider the experimental variables and their control Aware of the role of planning
Experimentation and data collection	Collect data using a variety of methods Perform experiments according to guidelines and able to use common instruments Faithful recording of experimental data and aware of the meaning of the duplicated collection of experimental data Being safety-conscious Aware of the importance of objective collection of experimental data
Analysis and reasoning	Analysis of experimental data Attempt to develop conclusion according to the observations and data Explain and describe the experimental data Aware of the importance of analysis and reasoning to experiments
Evaluation	Attempt to analyse the differences between hypotheses and experimental results Attend to the unresolved issues in the inquiries and discover new problems Improve the inquiry plan with reference to the experience gained Aware of the significance of evaluation
Exchange and co-operation	Able to write reports for the experimental inquiries Upholding principles while respecting others during co-operation Be co-operative Aware of the importance of exchange and co-operation

In the *HK-Guide*, 'scientific investigation' is a subsection under Skills and Processes,[3] where the intended learning targets that could be acquired through conducting scientific investigations are listed. Students are expected to:

- Ask relevant questions
- Propose hypotheses for scientific phenomena and devise methods to test them
- Identify dependent and independent variables in investigations
- Devise plans and procedures to carry out investigations
- Select appropriate methods and apparatus to carry out investigations
- Observe and record experimental observations accurately and honestly
- Organise and analyse data and infer from observations and experimental results
- Use graphical techniques appropriately to display experimental results and to convey concepts
- Produce reports on investigations, draw conclusions and make further predictions
- Evaluate experimental results and identify factors affecting their quality and reliability
- Propose plans for further investigations, if appropriate

(HK-Guide, pp. 9–10)

It is noteworthy that among all nine subsections under Skills and Processes, 'practical work' shares a few similar learning targets as 'scientific investigations', for example, students are expected to:

- Devise and plan experiments
- Select appropriate apparatus and materials for an experiment
- Interpret observations and experimental data
- Evaluate experimental methods and suggest possible improvements

(HK-Guide, p. 10)

By listing the expected learning targets related to Skills and Processes expected to be achieved through scientific investigation instead of spelling out the 'Components' of Scientific Investigations as presented in *CHN-Standards*, the *HK-Guide* might give a lesser impression of a rigid stepwise method of doing scientific investigations.

66.2.2 Interactions Between Science, Technology and Society

While the specifications on the discussion of the positive aspect of the technological applications of science are found in both documents as expected, *CHN-Standards* attends to the societal development brought by technological advances to a larger

---

[3] The learning targets of the Hong Kong physics curriculum are categorised into three domains: Knowledge and Understanding, Skills and Processes and Values and Attitudes.

extent. Students are required to appreciate 'the roles of the widespread use of heat engines in bringing about the changes towards science, *social development and the mode of living*'. (p. 22, emphasis added), while the specification in the *HK-Guide* requires students to understand 'how major breakthroughs in scientific and technological development that eventually affect society are associated with new understanding of fundamental physics' (p. 49).

The *HK-Guide* also pays more attention to the controversies that can be caused by new technologies, for example, in the topic of Wave Motion, students are expected to develop understanding of the 'controversial issues about the effects of microwave radiation on the health of the general public through the use of mobile phones' (p. 38). Also, in the topic of Radioactivity and Nuclear Energy, students are 'to be aware of different points of view in society on controversial issues and appreciate the need to respect others' points of view even when disagreeing; and to adopt a scientific attitude when facing controversial issues, such as the use of nuclear energy' (p. 51).

On the other hand, the *CHN-Standards* only generally states that students should be 'aware of the social problems that are brought about by the technological applications of Physics' (p. 2); it is less emphasised on, if not silent, about controversial issues related to use of technologies. For example, in the topics of Energy Sources and Development of Society, it is suggested that students 'investigate the common pollutants causing air pollution' (p. 23) and 'understand the development and application of nuclear technology as well as its outlook' (p. 23). Yet contested views about the use of nuclear energy are not brought up.

The lack of suggested learning and teaching activities for discussion of controversial socioscientific issues in the *CHN-Standards* is strikingly consistent with the absence of the democratic argument as a reason for teaching NOS as stated by the Chinese science teacher educators reported by Wan and colleagues (2011). As the authors said,

> [T]he absence may be explained in terms of the political context in China… a socialist country governed by Chinese Communist Party. In such a less decentralized system, general public has relatively little voice in the public decision on social issues. (p. 1118)

66.2.3 Moral and Ethical Dimensions of Science

The only relevant content related to the moral and ethical dimensions of science in the *CHN-Standards* is about the positive image of scientists. The *CHN-Standards* suggests textbooks to 'use vivid information to exhibit their scientific spirit and their determined devotion to science' (p. 58). Scientists are to be honoured for their respectable character and selfless commitment to the development of science. The *CHN-Standards* also explicitly spells out the intention of using examples to illustrate such scientific spirit in order facilitate character building of learners.

In comparison, the perspective adopted by *HK-Guide* is more balanced and reflective. Students are suggested to discuss 'the roles and responsibility of scientists and the related ethics in releasing the power of nature' (p. 52) and address to the 'moral issues of using various mass destruction weapons in war' (p. 52). Unlike *CHN-Standards*, scientists as portrayed in the *HK-Guide* are not simply 'heroes' to be appreciated; the moral and ethical consequences of the technologies resulted from their endeavour are to be examined.

66.3 NOS as Portrayed in School Science Textbooks

Two sets of corresponding physics textbooks from each city, including the one published by People's Education Press (Centre for Research and Development on Physics Curriculum Resources of PEP 2004, 'PEP') and the one by Guangdong Education Press (Editorial Group for Physics Textbooks, Guangdong 2004, 'GEP') from Guangzhou, and the set published by Oxford University Press (Wong and Pang 2009, 'OUP') and by Longman (Tong et al. 2009, 'Longman') in Hong Kong, were studied.

Almost all NOS ideas that are commonly found in the official curriculums in the West (McComas and Olson 1998) are embedded in the textbooks used in both Hong Kong and the mainland China. It seems that the absence of corresponding NOS ideas in the official curriculums has not resulted in their absence from the textbooks. For instance, the text segments that could be deployed to exhibit the 'theory-laden nature of scientific processes', absent in *CHN-Standards*, could be found in the historical episodes included in the textbooks used in the mainland China. Similarly, while the 'creative elements of the scientific processes' are not included in *HK-Guide*, the use of analogical thinking in scientific process could be found in a small dose in the textbooks of Hong Kong. Considerable differences of NOS ideas presented in the textbooks of both sites are again from the three aspects described above.

66.3.1 Methods of Scientific Investigations

The implied message on the universality of scientific method is translated into concrete form in the textbooks of the mainland China. In PEP, a shortened sequence of the processes listed as 'key components of scientific investigation' (pp. 10–11, *CHN-Standards*) is diagrammatically presented as the common method to be used in science (Fig. 66.1). To illustrate such a sequence, the work of Galileo in the study of free-falling object is reconstructed and 'moulded' into the fixed sequence of steps shown in the diagram.

However, the textbooks in Hong Kong, unlike their mainland counterpart, do not produce a similar list in their texts for a less than impressive reason though: Both OUP and Longman mostly consist of 'cookbook'-type practical activities with the key purposes of facilitating students to learn the relevant target concepts and to practise experimental skills, which will be examined through written and

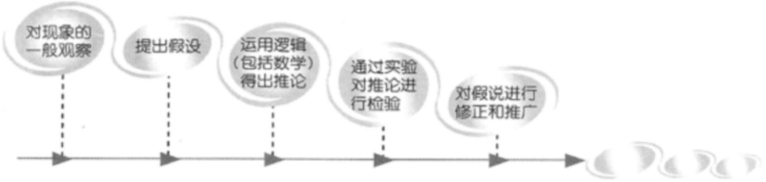

Fig. 66.1 Picture in one of the textbooks used in the mainland China (PEP 2004, Physics-1 p. 48) showing the steps of 'the scientific method' (The phrases in the picture, from left to right, mean 'General observation of phenomena', 'Hypothesizing', 'Obtaining corollary using logic (including mathematics)', 'Evaluation of the corollary through experiment' and 'Amendment and extension of the hypothesis')

practical examinations, respectively. The full detailed procedures of each practical activity are provided in the experimental workbooks, whereas the textbooks only provide an abridge version for reminding students the key features of the practical activity. The practical activities are more like heavily guided scientific investigations. Students can perhaps tell from the variation of the procedures of each practical activity that scientific investigations do not consist of a fixed set of stepwise procedures.

66.3.2 Interactions Between Science, Technology and the Society

The focus on the role of scientific and technological advances to the societal development in *CHN-Standards* is translated into textbooks in the mainland China. For example, the societal impact of the Industrial Revolution including that 'the venue of production changed from dispersed family production [houses] for agriculture and handcrafts to factories for centralized production', 'self-sufficient natural economy had evolved into market economy in which production and consumption are separated' and 'the development of cities facilitated the advancements of science, technology, education and cultural industries. Human society [were going] into the era of industrial civilization' (PEP 2004, Elective 1–2, p. 77) can be found in the textbooks.

The particular attention paid to the statements on 'the rise of manufacturing and service industries' and 'rise of market economy and capitalism' may be the result of the influence of the Marxist idea on historical periodisation, as similar influence of Marxism on the science teacher educators in the mainland China can also be found in Wan and colleagues (2012) and in the previous section of this chapter.

While textbooks are required to cover on the societal problems brought about by the products of science, the negative consequences of these applications are downplayed in PEP. For instance, safety problems stemmed from the use of nuclear energy are simply stated to be issues that 'are continuously being attended to'

(PEP 2004, Elective 1–1, p. 58), while two major nuclear meltdowns (the Three Mile Island accident and Chernobyl disaster) are just touched on (pp. 59–60) without any discussion of the related controversy.

However, GEP is not equally silent on socioscientific controversies, for instance, in the nuclear pollution problems brought by the Chernobyl disaster and the worries of the people on the use of nuclear power, which are natural results, are being mentioned (GEP 2004, Elective 2–3, p. 89). However, it is still attempting to contain students' worries by providing information like 'the nuclear reactors use low-enriched uranium… As such, reactors will not explode like nuclear bombs.' (GEP 2004, Elective 1–2, p. 50) to ensure students will not overreact towards the possible nuclear hazards.

On the other hand, for the societal implications of science and technology, the controversy about the use of nuclear energy is included in the OUP, and this corresponds well to the specifications in *HK-Guide*. In its discussion, the authors deploy a cartoon showing two demonstrations organised by pro- and anti-nuclear camps to represent the conflicting views presented on both sides (Radioactivity p. 90). Besides being told that there may be controversies, students are guided to study them. For instance, in the discussion of the possible harmful effects brought by the overhead power cables, students are required 'to find out … action taken by pressure groups and the response of electricity companies' (Electricity p. 280). The socio-scientific conflicts among different stakeholders and groups are being investigated.

However, in *Longman*, the impacts of science and technology on the society are superficially covered. Moreover, socioscientific controversies are mostly replaced by scientific findings on the possible health effects, as in the case of the overhead power cables. Socioscientific controversies are reduced to scientific colloquia:

> Some researches indicate that exposure to changing electric and magnetic fields from transmission lines may incur a number of health problems. These include leukaemia, cancer, miscarriage, clinical depression, etc. However, these conclusions are solely based on statistical studies … The detailed mechanism is still unclear. (*Longman* Vol. 4, p. 440)

66.3.3 Moral and Ethical Dimensions of Science

The particular specification on the need for the textbooks to portray scientists as good models of students results in the narratives in *PEP* that describe scientists as extraordinarily moral such as the despise of wealth and title as presented through the example of Faraday and having the 'courage' in making the difficult decision to suggest the use of atomic bombs (which is unlikely to be presented as such in the curriculum artifacts of the West):

> Some scientists, especially those escaped from the Fascist persecution, had a premonition about the threat of atomic bombs especially after they had heard that Germany had accelerated the research on chain reactions… On July 1939, nuclear physicist Szilard and others found Einstein and wished he could use his status to urge United States to produce atomic bombs before Germany had done so… (PEP 2004, Elective 3–5, pp. 84, 85)

Similar narratives of scientists' advocacy on the use of atomic bombs to counter the possible threats can be found in the chapter of atomic physics in *GEP*. However, a more reflective stance is taken. The text initiates a discussion on whether scientists should be free from the moral consequences of their work:

> Should people develop nuclear technology if both the pros and cons are taken into account? Some say scientists should care about science *per se*, while the impacts of science and technology to the society should be under the care of sociologists. Do you agree? (*GEP* Elective 3–5 p. 88)

The textbooks in Hong Kong also invite students to reflect on the moral responsibility of scientists. The deaths, injuries and sicknesses resulted from the use of atomic bombs in World War II are mentioned, and rhetoric that attempts to identify scientists' responsibility of using atomic weapons was used (*OUP*, Radioactivity p. 96).

In *Longman*, the moral and ethical aspects are pointed out but not discussed in depth. For example, while 'international race of nano-weapons' and the 'technology of changing and even constructing DNA' are said to cause much impact on ethical values (Atomic World, p. 149) and nuclear energy is said to be able to 'destroy our civilization if it is misused' (Radioactivity, p. 108), no further discussion is following these brief mentions.

From the comparison of the official curricula in both sites, it can be seen that there are differences between mainland China and Hong Kong regarding their inclusion of NOS ideas in the official curricula. There are also significant differences in terms of the inclusion and the focus of the NOS ideas in the textbooks. It is obvious that some messages (overt and covert) in the official curricula could (and sometimes fail to) influence the corresponding textbooks. Given the important status of textbooks in the science classrooms in both mainland China and Hong Kong, a follow-up study in identifying how other factors, on top of the official curricula, play their roles in shaping the NOS ideas found in the textbooks is being conducted.

66.4 Preparing Science Teachers to Teach NOS in Mainland China

Although NOS has appeared in the revised science curriculum documents in mainland China, the training is mostly dependent on the initiative of science teacher educators in Normal (teacher training) Universities. There are no large-scale teacher professional development projects funded by the government in developing in-service teachers to achieve a critical number of teachers in implementing the new curriculum goals. It appears that the current priority for science education reform of the Chinese government is more concerned with promoting inquiry-based science teaching and learning. Nevertheless, as reported in recent studies (Wan 2010; Wan et al. 2011, 2012), there are a number of Chinese science teacher educators teaching NOS to prospective science teachers in their courses for the bachelor degree of science education.

The study by Wan and colleagues (2012) revealed the influence of Marxism on these educators' conceptions. Although, during the interviews in this study, the factors influencing Chinese science teacher educators' views of NOS had not been intentionally asked, three science teacher educators explicitly stated that their NOS views are influenced by Marxism, especially dialectical materialism, which had been taught since their school time:

> My understanding of NOS is influenced by my early education of dialectical materialism. I had been taught of Marxism when I was in the school. It is common for the people grown up under the Red Flag[4] like me. Although it is too politicized in China, I feel most of its arguments are right, especially for those on natural philosophy…When I started to read the literature on NOS, I made use of my knowledge of dialectical materialism to understand it. (Wan et al. 2012, p. 16)

In addition to such general arguments, the influence of Marxism on Chinese science teacher educators' conceptions in NOS content to be taught is reflected in some specific aspects of the findings in the study.

66.4.1 Realist Views of Mind and Natural World

It is rather rare to find realist statements in the Western literature on NOS instruction. Even when it is found in *Science for All American* (American Association for the Advancement of Science [AAAS], 1990), one of few found by the authors, the tone adopted to present it is very assumptive:

> The world is understandable…Science *presume*s that the things and events in the universe occur in consistent patterns that are comprehensible through careful, systematic study. Scientists believe that through the use of the intellect, and with the aid of instruments that extend the sense, people can discover patterns in all of nature. … Scientist also *assumes* that the universe is, as its name implies, a vast single system in which the basic rules are everywhere the same. Knowledge gained from studying one part of the universe is applicable to the parts. (AAAS 1990, p. 2, authors' emphasis)

Wan et al. (2012) found that realist understandings of mind and natural world were considered by more than half of Chinese science teacher educators as scientific worldview and suggested by them as NOS content to be taught:

> One aspect of NOS is some basic thoughts guiding scientific investigation, including basic understanding of matter, motion…These scientific worldviews included understandings that … *the world is material*, all matters in world are *connected*, such connections are universal, *matters are in constant motion*, there are rules underlying such motion, and all these connection and rules are knowable to human being. (p. 14)

---

[4] Red Flag means the flag of Chinese communist party. Actually, red is the colour of all communist parties. The people grown up under the Red Flag refer to the people that are under influence of communist party.

The statement cited above reflects several core elaborated realist arguments:

(a) The existence of an external world that is independent of the observer
(b) The universality and constancy of connection in the world
(c) The possibility of our mind to know the external world and connections within it

These three statements are the prerequisites to arrive at the final and core argument of realism, i.e. the existence of the corresponding relationship between scientific knowledge and natural world. Without the existence of an independent material world, it is meaningless to discuss the relationship between scientific knowledge and natural world. The major form of the scientific knowledge is the universal and constant connection between variables, so if it is believed that there is no such universal and constant connection existing in the real world, the natural conclusion will be that such corresponding relationship cannot possibly exist between scientific knowledge and natural world. Even with the conditions of (a) and (b), if we do not admit that we can, through the use of the intellect and with the aid of instruments that extend the sense, discover such connection in the world, such a corresponding relationship is still problematic.

Indeed the choice of the words and the tone adopted by the Chinese science teacher educators are rather affirmative. This tendency is consistent with Marxist tradition, where realist epistemology is believed by Marxists as the right philosophy or worldview to guide scientists. Actually, on the basis of their materialist ontology, Marxists hold the realist epistemology (Curtis 1970; Farr 1991; Murray 1990), which admits the knowability of the material world. In Stalin's formulation: 'The world and all its laws are fully knowable … there are no things in the world which are unknowable, but only things which are as yet not known' (Stalin 1985, p. 18). He was elaborating Engel's contention that:

> natural scientists may adopt whatever attitude they please, they will still be under the domination of philosophy of science. It is only a question whether they want to be dominated by a bad, fashionable philosophy or by a form of theoretical thought with rest on acquaintance with the history of thought and its achievement. (Engels 1976, p. 558)

For Marxists, such theoretical thought includes the realist epistemology described before.

Although the core meanings of the excerpts are similar to the popular realist statements, there is still some difference as reflected in the emphasised words. First, emphasising that the world is material may reflect a materialist tendency, which is not necessarily held by realists – many realists grant the existence of nonmaterial things (fields, etc.). Second, the concepts of connection and change, which are not commonly included in the popular realist statements, are obviously emphasised in the above excerpts. However, the concepts of connection and change are the basic points of dialectics in Marxism, so some popular Chinese textbooks of Marxism integrate them with materialism and realist arguments to make a summary of Marxism principles. Hence although the possibility may not be totally excluded that the appearance of this NOS element and its high frequency is the result of the influence of other philosophical theories, the above clues indicate that it might more probably be the outcome of the influence of Marxism.

66.4.2 Truth-Approaching Nature of Scientific Knowledge and Science as the Pursuit of Truth

There are also other two realist NOS elements found in the study, i.e. truth-approaching nature of scientific knowledge and science as the pursuit of truth, whose meanings are very similar. The first believes that 'scientific knowledge as *relative truth*…Although it may never arrive at the state of *absolute truth*, its development is a process of continuous progression towards the truth in the objective world' (Wan et al. 2012, p. 16). The idea that science cannot obtain final truth but nevertheless can progressively obtain better approximations to the truth was enunciated by Karl Popper and called 'verisimilitude'. At the same time, the second argues that 'the goal of scientific investigation is to pursue truth, to reflect the real picture of the objective world…Science is unlike art. Art aims to pursue aesthetics, which allows departure from the fact and reality. But science investigation does not allow it' (Wan et al. 2012, p. 15). Although they were not suggested as frequently as the scientific worldview, if we count together the number of educators who have suggested them, there will be a total of ten. However, these two elements are hardly found in most recent science education curriculum in the West and academic publications on NOS studies. Such a feature in Chinese educators' conception is consistent with Marxist realist epistemology introduced before.

It can be also found that the terms *relative truth* and *absolute truth* were used as a pair by Chinese science teacher educators to describe truth-approaching nature of scientific knowledge. Truth is an important issue in many other branches of philosophy, but it is uncommon to couple these two terms to discuss the nature of knowledge in their literature. On the contrary, since being used by Lenin in his work *Materialism and Empirio-criticism* (Lenin 1977), this pair of terms has been popularly used among Marxists:

> Human thought then by its nature is capable of giving, and does give, absolute truth, which is compounded of a sum-total of relative truths. Each step in the development of science adds new grains to the sum of absolute truth, but the limits of the truth of each scientific proposition are relative, now expanding, now shrinking with the growth of knowledge. (Lenin 1977, p. 135)

Similar statements can be found in almost all the Chinese books on Marxism. Therefore, the appearance of this pair of terms is another indication of the influence of Marxism on Chinese science teacher educators' conception.

66.4.3 Logical Thinking in Scientific Investigation

Logical thinking in scientific investigation was considered by 15 Chinese science teacher educators as important for a scientific worldview and suggested by them as NOS content to be taught. It was depicted by a chemistry teacher educator:

> Induction and deduction are both important logical methods in scientific investigation. Deduction is from the general theory or concepts to the specific conclusion or facts…On the contrary, induction is the reasoning from the specific conclusion or facts to the general theory or concepts…I feel human understanding of the world is an endless process from the specific to the general, and then to higher level of the specific. It is a spiral process. (Wan et al. 2012, p. 12)

On the contrary, this NOS element is uncommon in the Western literature on NOS instruction. And even it is found, little elaboration is made. The caution about elaborating this element in the West may be due to the controversies between inductivism and deductivism in the philosophy of science. However, as reflected in the data, Chinese science teacher educators did not seem to concern conflicts between them. On the contrary, deduction and induction were considered as something like a unity of the opposite. This point is rather similar to Marxist view. ‘Induction and deduction belong together…Instead of one-sidedly raising one to the heavens at the cost of the other, one should seek to apply each of them in its place, and that each completes the others’ (Engels 1976, p. 519).

66.4.4 Empirical Basis of Scientific Investigation, General Process of Scientific Investigation and Progressive Nature of Scientific Knowledge

As indicated in the paper, except realist understanding of mind and natural world, the other four NOS elements suggested by more than a half of the educators in this study as NOS content to be taught are all NOS elements related to empiricism, i.e. empirical basis of scientific investigation, logics in scientific investigation, general process of scientific investigation and progressive nature of scientific knowledge.

The empirical basis of scientific investigation emphasises the role played by observation and experiment in the process of scientific investigation. As stated by one educator, ‘empirical method is one of major features of scientific investigation since whether the results or arguments in science will be accepted or not will depend on the result of testing through observation or experiment’ (Wan et al. 2012, p. 10). The origin of the empirical nature of scientific investigation can be traced back to the empiricism in the philosophy of science, emphasising the crucial role of human senses in the generation of scientific knowledge. Just relying on the empirical data cannot give a full explanation of the development of the scientific knowledge. In order to establish the validity of the scientific knowledge, it is necessary to provide a method to bridge between empirical data and scientific knowledge. The empiricist philosophers of science suggested that logic would serve such a purpose. Therefore, logics in the scientific investigation are also an empiricist NOS element.

General process of scientific investigation means a set of elements of conducting scientific research. It usually ‘starts with a question, proceeds then with proposing some hypotheses or arguments to the question, testing such hypotheses or arguments through observation or experiment, drawing some conclusions and at the end communicating such conclusion so as to convince people of the conclusions’ (Wan et al. 2012, p. 13). The discussion on general process or method of science can find its origin in empiricist philosophy of science. Both inductive empiricists and deductive empiricists were concerned to provide a scientific method. For inductive empiricists like Francis Bacon (1562–1626), the scientific method generally consists of four steps: observation and experimentation, classification, generalisation and testing. But deductive empiricists, like Karl Popper (1902–1994), think that the only logic that science requires is deductive logic. The method of science advocated by Popper is known as hypothetic-deductive method, which consists of the following steps (detailed description of Popper’s methodology is given in Popper 1959):

(a) Formulate a hypothesis (H).
(b) Deduce an empirical consequence (C) from H.
(c) Test C directly.
(d) If C is acceptable under the scrutiny of sense experience, return to step (b) and obtain another C for the further testing of H.
(e) If, on the other hand, C is rejected, H should be rejected as a consequence of modus tollens.

Regardless their differences in the specific steps included in the process of scientific investigation, the inductive empiricists and deductive empiricists are common in believing that there should be a general process of scientific investigation.

Chinese science teacher educators argued that ‘science accumulates and progresses in its own self-correcting process. Most of other subjects do not have such a feature…The typical example is art. If anyone wants to revise de Vinci’s Mona Lisa, who can produce a one better than the original?’ (Wan et al. 2012, p. 14). Stating the development of scientific knowledge is an accumulative or a progressive process is a typical stance originating in empiricism philosophy of science. The empiricists commonly conceive the development of science as a process that the replaced theories are reduced (and thus absorbed) into the replacing theory. For example, they take Newton’s theory as being reduced to Einstein’s theory. On the basis of such kind of understanding, the development of scientific knowledge is naturally considered as cumulative and continuous. In contrast with the understanding of the development of scientific knowledge as a process of replacement and absorption, it was thought by Kuhn (1970) that *scientific revolutions* also exist in the development of scientific knowledge, during which a process of replacement and displacement happens, rather than replacement and absorption.

Some interview data indicated that the popularity of Chinese science teacher educators’ inclusion of empiricist NOS elements in their instruction may also be partly caused by Marxism. As explicitly stated by two educators during the interview:

> I believed dialectical materialism since I was young…I think it’s consistent with the realist and empiricist philosophy of science, so I choose to focus on these classical NOS elements in my teaching. (Wan et al. 2012, p. 18)

Practice is the crucial concept in Marxism, which is considered as the starting point, the basis, the criterion and even the purpose of all knowledge (Mao 1986).[5] As stated by Marx (1976), 'the question whether objective truth can be attributed to human thinking is not a question of theory but is a *practical* question … the dispute over the reality or non-reality of thinking that is isolated from *practice* is a purely scholastic question' (p. 3) (authors' emphasis). Here, *practice*, in plain words, means the activity of applying mind into reality. For example, when some hypotheses are generated during the process of doing scientific investigation, we need to predict what phenomena are to be observed if the hypotheses are correct. On the basis of such predictions, appropriate scientific experiments are designed. The results of the scientific experiments are the evidence of supporting or refuting such hypotheses. The action of designing and doing experiments is a process of applying ideas into reality, so it is a kind of *practice*.

During the process of teaching, we use a certain kind of educational theory to guide the design of our teaching activities. If we find that students learn better, such a result is the evidence to support this educational theory. This kind of teaching activity is also *practice*. In fact, during the process of applying our mind into reality, we can, at the same time, get the responses from the reality through our sense experience, which can be not only empirical evidence to support or refute our mind, but the resources of generating new ideas. It is not difficult to note that empirical evidence, which is emphasised by empiricist epistemology, is implicitly integrated into the concept of *practice* in Marxism. Thus it is believed that Marxist philosophy, to a large extent, is consistent with empiricist epistemology (Creaven 2001). Of course, except the logics in scientific investigation, no addition clue in the wording can be found for the other three NOS elements to link their origin of Marxism. They may be influenced by Marxism in a more indirect manner.

Unlike the West where most science teacher educators focus on the contemporary views of NOS, most Chinese science teacher educators participated in Wan's (2010) study tend to put greater emphasis on realist views of science, though many of them are also knowledgeable about the contemporary views of NOS.

66.5 Preparing Science Teachers to Teach NOS in Hong Kong

In stark contrast to mainland China, Hong Kong science teacher educators have received continuous funding and support from the Education Bureau (EDB) of the Hong Kong Government in conducting a series of teacher professional development (TPD) and research projects to prepare teachers to develop students' understanding of NOS. As said in the previous section, science teacher educators and teachers in

---

[5] Mao Zedong first elaborates the concept of practice in his classic article 'On Practice: on the relation between knowledge and practice, between knowing and doing' written in July 1937, which is collected in various versions of Selected Works of Mao Zedong. The specific article cited here is this one included in Mao (1986).

mainland China put the highest priority in practising inquiry-based teaching and learning in science classrooms. Most teacher seminars and national teaching competitions are mainly centred at promoting teachers' pedagogical skills in carrying out inquiry-based teaching and learning. Most resources are allocated to equip the school laboratories with modern apparatus and equipment for conducting inquiry activities. It may be a reason why there have been no reports about the regular practice of teaching NOS in school classrooms in mainland China.

For Hong Kong, learning science through laboratory-based activities has been common at school level (albeit the activities are often carried out through 'cookbook' approach). School-based assessment on practical work or investigative studies have also been implemented in the 1980s starting from chemistry, followed by biology in the 1990s and physics in the 2000s. The emphasis on hands-on practical activities in school science was largely a result of the influence of the British educational system in which the Nuffield Curriculums had been influential since the 1970s until 2012 when the Hong Kong Advanced Level Examination[6] was replaced by the Hong Kong Diploma of Secondary Education Examination. Thus the school laboratories are mostly well equipped already. For the recent reform in science education which aims to promote students' scientific literacy, NOS turns out to be an area that most science teachers are unfamiliar with and hence EDB sees an urgent need to provide funding in support of TPD projects along the direction of the new curricular goals.

In this section, we review the decade of efforts by the group of science educators of the University of Hong Kong (HKU) in promoting teachers' understanding of NOS and pedagogical skills in implementing NOS teaching in their classrooms. Our sharing will situate in the 8-year experience in learning to teach NOS of a physics teacher, Henry. Henry first started learning about some general NOS ideas since 2003 when he studied for his Postgraduate Diploma in Education (PGDE) course, major in physics at HKU. Through the reflection on Henry's learning journey based on the detailed records of his learning and our TPD programs, we highlight some critical stages of his learning journey. We hope our in-depth reflection will provide insights on the design of effective TPD for similar future initiatives.

66.5.1 A Decade of Effort in Preparing Teachers for the Reformed Curricular Goals

In response to the curriculum reform in Hong Kong, science teacher educators have initiated a series of research and TPD projects since early 2000 to support pre-service and in-service science teachers to teach NOS. We are cognisant of the

---

[6] The examination was similar to the British General Certificate of Education Advanced Level Examination except that it was much more competitive due to the very low university admission rate in Hong Kong.

numerous problems and challenges identified in the West. Lederman's (1992) critical review came to a disappointing conclusion that both students and science teachers have inadequate understanding of NOS (Lederman 1992). There is however empirical evidence that can inform ways to improve NOS understandings. Explicit and reflective approaches and strategies using historical account of scientific development and/or through scientific inquiry in teaching NOS can support learner development of sophisticated NOS ideas (Abd-El-Khalick and Lederman 2000; Khishfe and Abd-El-Khalick 2002). Yet, teachers with good understanding in NOS still face many constraints including concerns for student abilities and motivation (Abd-El-Khalick et al. 1998; Brickhouse and Bodner 1992), lack of pedagogical skills in teaching NOS (Schwartz and Lederman 2002) and lack of teaching resources (Bianchini et al. 2003) particularly those in local contexts and language (Tsai 2001). Effective NOS teaching also depends on teachers' belief in the importance of teaching NOS (Lederman 1999; Tobin and McRobbie 1997) and their conception of appropriate learning goals and teaching role (Bartholomew et al. 2004).

66.5.1.1 Inadequate NOS Understanding: Missing the Target NOS

In support of the implementation of the revised junior secondary science curriculum, Tao, Yung, Wong, Or and Wong (2000) wrote a new series of textbooks which included four science stories on penicillin, smallpox, Newton's Law of Universal Gravitation and the treatment of stomach ulcers. Although these stories were designed such that teachers could highlight the NOS aspects through an explicit approach (Abd-El-Khalick and Lederman 2000), it was found that students' learning of NOS based on these stories was disappointing (Tao 2003). In fact many teachers, including Henry, considered the stories good for arousing student interest without attending to the primary purpose of teaching relevant NOS idea, as shared by a junior science teacher who came to realise his oversight after he attended the NOS sessions in our PGDE courses in early 2000s:

> I found the story on stomach ulcers very interesting....Marshall tested his hypothesis by trialing out himself....Students all enjoyed the story… I only realise now that there are deeper meanings behind the story and other important learning outcomes to be achieved through it and other stories.

We learnt from this experience that availability of teaching resources would not by itself result in teachers making use of the materials to teach NOS unless teachers had the ability to understand and appreciate the intended learning outcomes of the instructional materials. It is likely that they would overlook the targeted learning objectives (McComas 2008) and cling onto the parts which were more appealing to them (dramatic stories which promote students' interest). We also reckoned that there were some inadequacies of these relatively 'old' stories. Teachers and students expressed that though these stories aroused their interests, they happened quite a while ago. Those who did not have the historical and cultural backgrounds of the scientific discoveries and inventions would fail to develop an in-depth understanding of, and hence appreciate, the thought processes of the scientists related to what they encountered at their time.

66.5.1.2 Effective Learning of NOS Contextualised in the SARS Story

In summer 2003, when the crisis due to the severe acute respiratory syndrome (SARS) in Hong Kong was coming to an end, we saw a golden opportunity to turn the crisis into a set of meaningful instructional resources which might help address the issues raised above. The SARS incident was a unique experience that everyone in Hong Kong had lived through and the memories of which would stay for years. At the beginning of the outbreak, the causative agent was not known, the pattern of spread was not identified, the number of infected cases was soaring, yet an effective treatment regimen was uncertain. It attracted the attention of the whole world as scientists worked indefatigably to understand the biology of the disease, develop new diagnostic tests and design new treatments. Extensive media coverage kept people up to date on the latest development of scientific knowledge generated from the scientific inquiry about the disease. As anticipated we identified many interesting aspects of NOS based on our interviews with key scientists who played an active role in the SARS research, analysis of media reports, documentaries and other literature published during and after the SARS epidemic.

The SARS incident illustrated vividly some NOS features advocated in the school science curriculum. They included the tentative nature of scientific knowledge, theory-laden observation and interpretation, multiplicity of approaches adopted in scientific inquiry, the interrelationship between science and technology and the nexus of science, politics, social and cultural practices. The incident also provided some insights into a number of NOS features less emphasised in the school curriculum. These features included the need to combine and coordinate expertise in a number of scientific fields, the intense competition between research groups (suspended during the SARS crisis), the significance of affective issues relating to intellectual honesty, the courage to challenge authority and the pressure of funding issues on the conduct of research. The details on how we made use of the news reports and documentaries on SARS, together with episodes from the scientists' interviews to explicitly teach the prominent features of NOS, can be found in Wong et al. (2009). Since January 2005, we have been using the SARS story in promoting understanding of NOS of hundreds of pre-service and in-service science teachers. The learning outcomes have been encouraging (Wong et al. 2008).

66.5.1.3 Integrating NOS Teaching into Teaching of Science

While the SARS story has been effective in promoting NOS understanding, there was still a lack of NOS instructional materials closely related to the school science curriculums. We also planned to produce instructional materials grounded in more local contexts and in both English and Chinese language to suit the need of local schools using either English or Chinese as the media of instruction. Thus, in September 2005, we embarked on a 2-year project, Learning and Teaching about Science Project (LaTaS), which aimed to produce local NOS curriculum resources[7] and prepare teachers for teaching NOS. We took the advice of Hodson (2006) that:

> Curriculum materials need to have a "street credibility" that can only be gained when they are developed *by* teachers *for* teachers. (p. 305)

Thus we deliberately involved teachers at the beginning stages of the design process of teaching materials. More than 50 senior secondary science teachers worked together with the university team members to develop 12 sets of teaching resources which integrate NOS knowledge with subject knowledge for the new senior secondary biology, chemistry and physics curricula (CDC 2007). Efforts were made to include as many local examples as possible on top of some classic stories of science. The topics included development of teaching materials on topics including *Disneyland in Hong Kong* to be integrated in the teaching of ecology, an abridged version of the *SARS Story* to be integrated in the teaching of infection diseases, *Nature of Light* to be integrated in the teaching of wave properties of light, *Ban of Eating Shark Fin* to be integrated with the teaching of reaction rate, etc. By specifically choosing relevant socioscientific issues or well-known classic stories of science, teachers would be more ready and willing to practise NOS teaching by making use of the materials developed by the project team in their own science classrooms. Teachers' classroom practice helped us refine the teaching materials.

Henry was among one of the teachers who helped to try out the set of instructional materials on LASIK. Like other teachers, Henry found the in-depth analysis of the lesson video of their own practice most valuable in addressing some areas for improvement. Henry noted that he had missed a number of golden opportunities in receiving student good answers on questions related the interaction of science-technology-society (STS). Unlike the usual discussion on physics questions in which teachers would guide his students to come to 'the solution', in the discussion of questions related to STS, there could be many reasonable responses. Although he was not satisfied with his implementation of the NOS activities, he was pleased to have identified the areas of improvement and was confident that he could do a much better job in his next NOS teaching. An important encouraging factor for Henry to continue NOS teaching was his realisation of students' ability and interest in learning NOS as evident in the good responses by the students (though missed by him during the trial lessons).

Henry further expressed that he found his students liked the hands-on activity that simulated the LASIK surgery[8] (Wong 2004) very much, but he found it awkward (so was his students) to have another whole lesson following the LASIK surgery to cover its related NOS and STS activities. Henry said, 'it wasn't the style of my physics teaching and my students' style of learning physics'.

---

[7] Curriculum materials developed in this project are accessible at http://learningscience.edu.hku.hk/

[8] Notes to technician/teacher on the preparation of the 'cornea' and the set-up can be found in the LASIK instructional materials at http://learningscience.edu.hku.hk/

Henry's reflection told us that it was likely that the ambition in having as many NOS activities trialled and refined within the limited project period might have given teachers an impression that an NOS lesson has to be heavily loaded with NOS activities. Henry's sharing also reminded us that we should not take it for granted that teachers could naturally integrate the NOS materials with the science knowledge covered in the textbook (written before the new curriculum) in a meaningful manner. Good integration of NOS activities with the subject knowledge also requires careful planning and practice by the teacher to match with his own teaching style and his students' learning style. Just like teaching of a science topic using a textbook, each teacher could have his own style in integrating the NOS materials developed in the LaTaS project into his science classroom.

66.5.2 Modifying and Enriching Available NOS Resources

Henry, as many other participating teachers, continued to practise NOS teaching in his lessons even after the LaTaS project ended in late 2007. There are various reasons for teachers to continue their endeavour: (1) prepare students for possible questions assessing on the NOS understandings in public examination, (2) students show interest in learning NOS, (3) aware of students' ability in learning NOS and (4) positive experience in support of the 'science learning argument' by Driver and her colleagues (1996).

In Henry's further attempts in teaching NOS in 2008, he decided to address the areas of improvement identified in his trial of the LASIK materials. Firstly, instead of cramming in too many NOS ideas in one or two lessons, he infused NOS at appropriate places in a series of three double lessons each of 80 minutes during the teaching of *Nature of Light* and *Electromagnetic Wave*. Secondly, instead of bringing up each NOS idea in a fragmented way, he organised the NOS ideas in an interrelated manner. Thirdly, inspired by the experience of further learning about NOS through the SARS story, Henry included some NOS ideas which are not commonly introduced in textbooks, e.g. competition among scientists and peer review, establishment of scientific knowledge as an outcome of consensus reached by scientists and model-building as one of the typical activities of scientists in their endeavour in the pursuit of understanding of the nature. Lastly, instead of just focusing on the widely cited seven NOS aspects advocated by Lederman (1992), he went beyond the list and introduced some apparently contrasting NOS features by situating them in relevant historical contexts.

In the first double lesson, he planned to review the four wave properties, introduce Young double-slit experiment and explain the interference pattern. He tailored some NOS activities developed in the *Nature of Light* materials in the LaTaS project. He made use of the controversial arguments between Newton and Huygens about the nature of light to highlight some 'relatively negative' features about the subjectivity in science. For example, he elaborated that (i) scientists could be very 'stubborn' in holding on their beliefs due to their beloved models in explaining the natural phenomena (theory-laden observation/inference/explanation), (ii) there were two camps of scientists (one supported particle model of light and the other supported the wave model of light) and so more than one scientific models might be found coexisting in explaining a specific observation or natural phenomenon and (iii) Newton was the 'winner' as a result of submission to authority even among scientists (when both models could explain reflection and refraction of light).

In the second double lesson, he planned to review interference of light and introduce single-slit and its associated concept about diffraction. He attempted to balance the 'relatively negative' NOS features with the 'relatively positive' NOS features by highlighting the empirical evidence of Young in support of wave theory of light. He enriched the existing materials by adding the story of Poisson's challenge to Fresnel's wave theory of light. Poisson, who was a believer of particle theory of light, challenged Fresnel's arguments towards wave theory due to the lack of experimental evidence of diffraction effect of light. However, when hard experimental evidence was produced by Fresnel with the help by Arago, Poisson had to convert his belief about the nature of light based on the convincing experimental evidence.

In a subsequent double lesson, Henry then made use of the story of the discovery of DNA as one of the applications of X-ray to highlight the competitive nature of scientists and building of models through scientists' imagination and creativity. Towards the end of the series of lessons on Light Wave, he even linked all the NOS aspects covered in the topic in the form a mind map to strengthen students' appreciation of the interconnectedness of NOS features. Figure 66.2 gives a reproduction of his summary on the blackboard during the last lesson of the series on *Nature of Light* and *Electromagnetic Wave*.[9]

66.5.3 Learning from Henry's Professional Growth in Teaching NOS

Through active and persistent reflection upon each attempt of NOS teaching, Henry, as other teachers having similar commitment, has come a long way from the learning of NOS to successful design and implementation of the lessons that teaching physics as well as NOS ideas in an interconnected manner. His exemplary teaching has received recognition by different stakeholders, including science teachers who are preparing themselves to teach NOS. EDB and University colleagues have also invited him for sharing the lesson series designed by himself. To him, the greatest reward of the long journey of professional development is probably the learning of his students. It was not difficult to tell from Henry's smile when his shared students' responses received in later lessons showing their good understanding of some

---

[9] Video episodes of the three series of lessons can be accessed at http://web.edu.hku.hk/knowledge/projects/science/qef_2010/d1/1b2_training_workshop.html

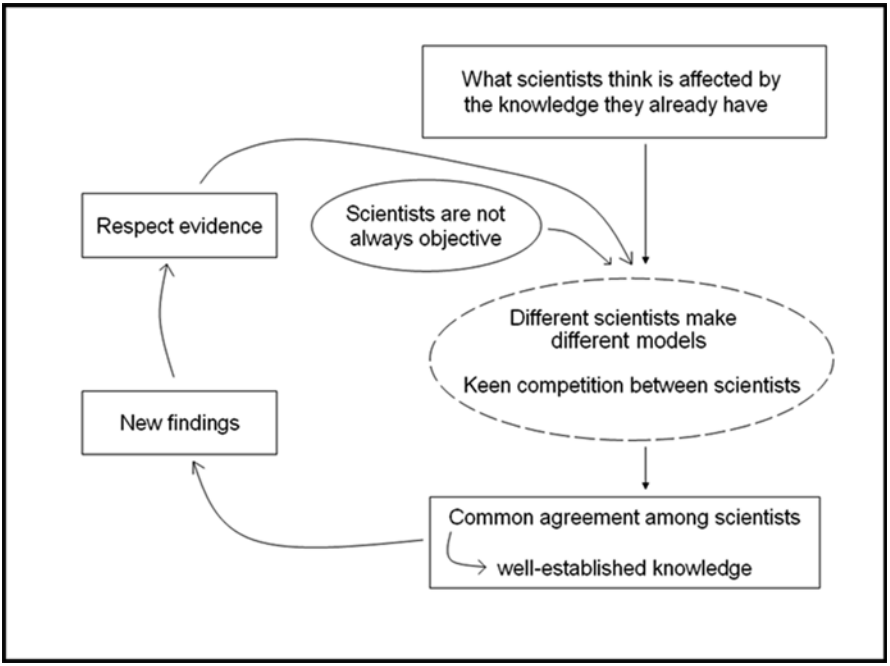

Fig. 66.2 A summary of the interconnectedness of NOS features given at the end of the lesson series

difficult NOS ideas like theory-laden observation. In his word, '*[NOS can] promote student interest in learning the content knowledge*' and '*students do learn NOS*'.

A year after the completion of the LaTaS project, EDB further supported us to conduct another 2-year project from 2008 to 2010 with a focus on the enhancement of teachers' pedagogical content knowledge (PCK) of teaching NOS. We have noted from Henry's 'revolutionary jump' in his learning curve when he attempted to plan his own lessons. Thus in the PCK project, at the outset of the project, we encouraged teachers not to simply modify and adapt the available teaching resources, but to proactively design their own instructional materials. This is indeed a goal that we wish teachers could ultimately achieve. We further explained our intention to the teachers by a Chinese proverb, (授人以魚,三餐之需;授人以漁,終生之用。). In English, it says 'Give a man a fish and you feed him for a day. Teach a man to fish and you feed him for a lifetime'.

66.6 Conclusion

In this chapter, we have compared the NOS ideas as portrayed in the curriculum standards documents, NOS ideas as portrayed in the textbooks and the teacher training for preparing teachers towards their teaching of NOS. We have also shared an exemplary lesson series conducted by a Hong Kong teacher in his classroom. Although there are variations of a few NOS aspects as portrayed in the official curriculum standards documents and school science textbooks as well as those taught in teacher training institutes, most prominent differences occur at the school classroom implementation. There are currently no reports on the implementation of NOS teaching in school science classrooms in mainland China regardless the similar degree of emphasis placed on NOS education in the official curriculum. On the other hand, the NOS teaching has taken root in Hong Kong science classrooms. The key difference mainly originates from the support and resources input from the government in realising the intended goals. We do see a related emphasis on learning science through inquiry-based approach which has taken off in science classrooms in many cities as evident in the annual national competition in mainland China since early 2000s. Schools with teachers gaining the awards will also receive funding as encouragement. In Hong Kong, the support from the government is provided to all schools through supporting institutes with experts in the area of focus and the most relevant and appropriate research and teacher professional development plans.

Siu Ling Wong is an Associate Professor and Assistant Dean (Programme) in the Faculty of Education at the University of Hong Kong (HKU). She received a B.Sc. in Physics and PGDE Major in Physics from HKU and received her DPhil in Physics from the University of Oxford. She had worked as a Croucher Foundation Postdoctoral Fellow in the Clarendon Laboratory and a Lecturer at Exeter College, Oxford. She is a National Research Coordinator of the Trends in International Mathematics and Science Study (TIMSS) for Hong Kong. She is a founding and executive member of the East-Asian Association for Science Education. She is also the leading author of the most popular physics textbook in Hong Kong. Her current research interests include nature of science, socioscientific issues and teacher professional development.

Zhi Hong Wan is an Assistant Professor in the Department of Curriculum and Instruction at the Hong Kong Institute of Education. He received a B.Sc. of physics education from the Jingdezhen Institute of Education, a M.Phil. in educational psychology from Soochow University, and a D.Phil. in science education from the University of Hong Kong. Before starting his research in science education, he had taught middle school physics in Mainland China for 5 years. Zhi Hong's research focuses on how nature of science instruction is conducted and perceived in different social-cultural backgrounds and assessment for learning. He has authored more than 20 articles.

Ka Lok Cheng is a lecturer and Project Manager in the Faculty of Education at the University of Hong Kong. He previously worked in the Education Bureau of the Hong Kong SAR Government and facilitated the provision of school-based professional support services to teachers. He served as a school teacher of Chemistry for 6 years formerly. He earned his B.Sc. and M. Phil. in Chemistry and is currently a doctoral candidate in Science Education at the University of Hong Kong. He teaches sociology of education courses for student teachers at BEd and PGDE levels. His main research interest focuses on the history of science and nature of science ideas in the official curriculums and textbooks.

Chapter 67
Trends in HPS/NOS Research in Korean Science Education

Jinwoong Song and Yong Jae Joung

67.1 Introduction

The HPS/NOS in the science education plays roles in stimulating students' motivation, in illustrating humanistic aspects of science (Jung 1994; Matthews 1994), and in helping the understanding of scientific methods (Lederman 2007; McComas and Olson 1998; Matthews 1992). In the recent days, the National Science Curriculum of Korea also highlights the promotion of students' scientific literacy which requires students' understanding of HPS and NOS (MEST 2007b; MEST 2011).

Historically, HPS and NOS have largely been of a minor attention in Korean science education. Following its liberation from Japanese occupation following the World War II, Korea's modern school education considers science as one of the core school subjects. After the Korean War (1950–1953), along the continuous national policies for industrial rebuilding and economic development, science education has continued to be the subject of national attention and public's concern. Because of this relationship with national development, science education in Korea used to focus more on practical usefulness and manpower-building-oriented approaches. In other words, school science education has often been the sources of scientific and technical majors in earlier years and of more advanced and creative scientific and engineering specialists in recent years. As a result, in Korea, HPS and NOS have largely been of a minor attention.

Science education has been a subject of systemic research activities since the establishment of Korean Association for Science Education (KASE) (formerly

known as Korean Association for Research in Science Education: KARSE) in 1976. For the last 35 years, KASE has played the central role in researching, developing, and implementing issues of science education, mainly through its official journal, *Journal of Korean Association for Science Education* (JKASE) (formerly known as *Journal of Korean Association for Research in Science Education*: JKARSE) and biannual conferences. Beginning in 1978, JKASE was published every other year. In 1984 JKASE began publishing twice a year. Currently, eight issues (six issues in Korean and two issues in English) are published every year. As the most comprehensive and highly recognized journal, JKASE covers a whole range of areas of science education, i.e., informal as well as formal education and from preschool to tertiary levels.

Besides KASE, there are also several academic societies related to science education which target more specific groups of audience: for example, the Korean Society for Elementary Science Education (KSESE) established in 1970 and its official journal, *Journal of Korean Elementary Science Education*; the Korean Society of Biological Education (KSBE) established in 1968 and its official journal, *The Korean journal of Biology Education*; the Korean Earth Science Society (KESS) established in 1969 and its official journal, *Journal of Korean Earth Science Society*; the Korean Science Education Society for the Gifted (KSESG) established in 2008 and its *Journal of Science Education for the Gifted*; and the Korean Society for School Science (KOSSS) established in 2006 and its journal *School Science Journal*.

Similar to many countries and perhaps more strongly, science curriculum and science education research in Korea have been influenced by those in the United States. The aims of the National Science Curriculum and research trend of science education were largely similar to a decade's earlier versions of US ones. Nevertheless, the practice of school science in Korea has been inevitably dependent on social and educational conditions of the time in Korea. For example, exam-oriented, teacher-centered, and government-driven (science) education are the most prevalent conditions currently influencing Korean science education. These conditions, directly or indirectly, influence the practice and research activities of Korean science education, including HPS/NOS-related aspects. The Korean social environment that emphasizes students' hard work and high scores for entering good schools/universities makes difficult for school science education to be free from knowledge-oriented teaching and learning. And this environment would discourage for students to have ample experience to think and discuss the nature of and the historical content of science.

In this chapter, the status quo of HPS/NOS-related aspects of Korean science education are outlined, beginning with a brief summary of the history of National Science Curriculum which is the basic foundation of school science education. Next, the change of research trend of science education will be analyzed using the HPS/NOS-related papers published in JKASE for the last three decades. Finally, to find out how HPS/NOS has been incorporated in the practice of science education, HPS/NOS-related aspects in science textbooks and science teacher education will be explored.

67.2 A Brief History of National Science Curriculum of Korea

Korea has a centralized education system firmly based on its National Curriculum (Kim 2001). The National Curriculum is provided in the form of official document by the Ministry of Education, Science and Technology of Korea (MEST), and is mandatory to all schools from kindergarten to high schools. The National Curriculum of Korea has been revised regularly by the government since the first revision in 1954 (Park 2011). On average, the National Curriculum has been revised every 6–7 years (Kim 2001). At present, 2007 National Science Curriculum (MEST 2007a) is being applied to primary and middle school science education, and 2009 National Science Curriculum (MEST 2011), which is recently revised, is being applied to high school science education and will be implemented to primary and middle school after 2013.

The past curriculum reforms can be historically divided into three periods: the periods of Teaching the Syllabus (1945–1954), Course of Study (1954–1963), and Formal Curriculum (1963–present) (Kwon 2001). The period of Teaching the Syllabus was from 1945, the year of Korea's liberation from Japan, to 1954. During this period, the Korean government was the temporary government under the control by the US army. In this period, the curriculum (i.e., syllabus) was just a list of teaching items (e.g., "the existence of air," "space occupation by air," "the weight of air," "thermal expansion of air," and "compression and the use of air") without having objectives or any suggestions on teaching methods and evaluation. The syllabus of science contained not only science content but also practical arts content. Despite the inevitable influence from Japanese curriculum during the colonial rule, the school teaching during this period in large focused on the basic content and abilities of the subjects and also on overcoming the Japanese vestiges in people' spirit and everyday life.

The period of Course of Study (1954–1963) was officially named the first Korean curriculum, although there have been some debates over whether or not the Course of Study constitutes a formal curriculum. The objectives of science in this period were categorized into scientific knowledge, scientific inquiry, and attitudes toward science. The titles of content were expressed as questions (e.g., "How do the weather and seasons influence our everyday living?"). The Course of Study, however, did not include any suggestions on teaching and evaluation.

The period of Formal Curriculum can be further divided into three periods of school science curriculum: experience-centered curriculum (1963–1973), discipline-centered curriculum (1973–1981), and humanistic curriculum (1981–present). The experience-centered curriculum, that is the 2nd National Curriculum, was the first well-formalized curriculum which included objectives, content, and suggestions for teaching methods. The subjects on science were "Nature" for elementary school, "Science" for middle school, and 7 subjects (Physics I, II; Chemistry I, II; Biology I, II; and Earth Science) for high school. This curriculum was based on American progressive philosophy and emphasized everyday experience and science content.

The discipline-centered curriculum (1973–1981) was also influenced by the US science education innovation movement. The philosophy, objectives, content, and methods of teaching of the existing curriculum, i.e., the experience-centered curriculum, were changed completely. The new National Science Curriculum profoundly accepted the philosophy of discipline-centered curriculum proposed by J. S. Bruner and the Woods Hole Conference. This curriculum reorganized the content to reflect the basic concepts of science, changed the methods of instruction from rote memory to inquiry, and emphasized the teaching of science through discovery and problem-solving, students' voluntary involvement, and students' inquiry process skills. The science content of this curriculum included the five basic concepts: matter, energy, interaction, change, and life.

The humanistic curricula (1981–present) includes the 4th (1981–1987), 5th (1987–1992), 6th (1992–1997), 7th (1997–2007), 2007 Revised Curriculum, and 2009 Revised Curriculum.[1] The humanistic curricula were influenced mainly from the movements of "Science for All" and Science Technology and Society (STS). The discipline-centered curriculum had been criticized on the ground that the content was isolated from real-life situations and problems that students confront in everyday life and was too abstract and difficult for most students to understand (Kim 2001). The attention to "Science for All" and STS increased with such critiques. However, in the 4th curriculum, science content did not overcome the discipline-centered philosophy although new slogans, "Science for All" and STS, were introduced into Korean science education. The STS spirit did not explicitly appear in the objectives until the 5th curriculum. Since the 5th curriculum, "Science for All" and STS spirits were continuously strengthened until the present curriculum. One of the important changes in this period was the creation of a new combined or integrated high school science subject: "Common Science" in the 6th curriculum and "Science" in the 7th curriculum for G10, both emphasizing everyday science and decision-making. Another important change was the emphasis on scientific literacy including recognition of the relationship between STS and rational decision-making in the context of everyday life. In the 2007 and 2009 Revised Science Curricula, the terminology "scientific literacy" was expressed explicitly as the objectives of science education (MEST 2007a, 2011).

The 2007 Revised Science Curriculum, the latest curriculum applied to schools with textbooks, aims to help students understand the basic concepts of science through inquiry with interest and curiosity toward natural phenomena and objects. Students are expected to be able to develop the scientific literacy necessary for solving the problems of daily life creatively and scientifically (MEST 2009). In this curriculum, the content of "Science" includes the domains of motion and energy, materials, life, and earth and space, linking basic concepts with inquiry processes across grades and domains. In addition, these include Free Inquiry, which would provide students with the opportunities to select their own topics based on their interests, to enhance their interest in science, and to develop creativity.

---

[1] After the 7th Curriculum, the revision was to be made upon its demand, thus the new Curriculum was named with the revision year instead of calling 8th or 9th.

In addition, in this Curriculum, science learning is centered around various inquiry-based activities including observing, experimenting, investigating, and discussing. Learning emphasizes independent as well as group activities for nurturing scientific attitudes and communication skills, including criticism, openness, integrity, objectivity, and cooperation. Learning also stresses the comprehensive understanding of basic concepts, rather than acquisition of fragmented knowledge, and the ability to scientifically solve problems in daily life. The core concepts of Science are taught with a close relation to learners' experiences, and students are provided with opportunities to apply science-related knowledge and inquiry skills for problem-solving in society and their daily life. By learning about science, students are to be able to recognize the relationships between science, technology, and society as well as the values of science. The particular goals of the 2007 Revised Science Curriculum are as follows:

> The Science Curriculum aims to help students understand the basic concepts of science through inquiry into natural phenomena and objects with interest and curiosity and the development of scientific thinking and creative problem solving abilities. As a result, students will be able to develop the scientific literacy necessary for solving creatively and scientifically the problems of daily life. The objectives of the Science Curriculum are to educate students so they will be able:
>
> (a) To understand the basic concepts of science and apply them to solve problems in daily life.
> (b) To develop the ability to inquire about the nature scientifically and to use this ability for solving problems in daily life.
> (c) To enhance curiosity and interest toward natural phenomena and science learning, and develop an attitude to scientifically solve problems in daily life.
> (d) To recognize the relationship between science, technology, and society. (MEST 2009, pp. 12–13)

In 2011, the 2009 Revised Science Curriculum (MEST 2011) was introduced, in which the main objective was to raise students' scientific literacy for creative and rational problem-solving. In addition, 2009 Revised Science Curriculum emphasizes the fusions among science disciplines (i.e., physics, chemistry, biology, and earth science) as well as different fields (i.e., science, technology, engineering, arts, and mathematics – often called STEAM).

Since the middle of 1980s, the description related to HPS/NOS in Science Curricula has been gradually increased. The 5th Science Curriculum, announced in, began to express the attention to NOS by declaring as its objective "… through the experience with the nature, students are expected to have interest in science and scientific literacy." The 6th Science Curriculum announced in 1992 included STS education in its objectives by saying "… students are expected to know that science influences technological developments and has close links with our everyday life." And its section for Teaching and Learning Methods stated "… to appreciate the relationship between science and life by using things available around our daily life, and to make use of what they learned during science classes in their daily life." This kind of STS-related descriptions has appeared ever since the 6th Science Curriculum. The 6th Science Curriculum also began to include HPS/NOS-related descriptions, such as "… to stimulate students' interest in and curiosity toward science through the appropriate introduction of content related to science, scientists, and current issues…." Furthermore, 2007 Science Curriculum, the curriculum focused on "scientific literacy" and creativity, presented more clearly HPS/NOS-related descriptions, such as "… to prepare the list of science books for the effective teaching of writing and discussion on the basis of materials on cutting-edge science, scientists, the history of science" (MEST 2007a, p. 25), "… to guide students to read materials on science and scientific issues, and, through the writing and discussion based on the materials, to improve their skills of scientific thinking, creative thinking, and communication" (MEST 2007a, p. 25), and "… by introducing content on cutting-edge science, scientists, current issues, to stimulate students' interest in and curiosity toward science" (MEST 2007a, p. 25).

In 2009, the National Science Curriculum (MEST 2011) emphasized scientific literacy, creative and rational problem-solving, and integrated approach, similar descriptions on HPS/NOS. For instance, the objectives included elements of scientific attitudes (such as critical ability, openness, honesty, objectivity, and cooperation) and communication skills. In particular, for G7-9 level, there is a part called "What is science?" through which students learn about science and its relevance to everyday life and develop their interest and curiosity in science. In addition, another part, "Science and Human Civilization," is included to understand scientific contributions to human civilization based on historical facts and to develop a viewpoint to see science in connections with technology, engineering, arts, and mathematics (MEST 2011, p. 66). Furthermore, its Guidance for Teaching and Learning suggests "to teach with appropriate examples the content of NOS-related issues, such as the tentativeness of science, multiplicity of science methods, feature of scientific models, the difference between observation and inference" (MEST 2011, p. 68) and recommends to introduce stories of scientists, history of science, and current scientific issues.

As illustrated so far, in general HPS/NOS-related content in Korean Science Curricula have been largely included in connection with STS approach and became recently to include a wider range of content.

67.3 HPS/NOS in Research Papers in Korea: Based on the Analysis of Papers Published in JKASE

The *Journal of the Korean Association for Science Education* (JKASE, http://www.koreascience.org/) began in 1978 and, ever since, has been the most representative science education journal in Korea, publishing the largest number of research papers on science education in Korea across the whole range of science education. In this section, the results of analysis of the trends of HPS/NOS-related papers published in JKASE for the last three decades will be reported and discussed. JKASE publishes eight times annually. Currently six of these issues are written in Korean and two issues are written in English. The papers analyzed here were from issues in both languages.

67.3.1 Types of HPS/NOS-Related Papers and Classification Method

The HPS/NOS-related papers that appeared in JKASE were classified according to its four dimensions, that is, research theme, research method, target subject, aims, and results. Referring to existing literatures which have collections of HPS/NOS-related papers (such as, *The History & Philosophy of Science in Science Teaching* (Herget 1989), *More History & Philosophy of Science in Science Teaching* (Herget 1990), *The Nature of Science in Science Education: Rationales and Strategies* (McComas 1998)), a rough category framework was developed for the classification. Based on this rough category framework, each paper was classified and then checked to see if the paper properly fit that particular category. In doing so, the framework was repeatedly revised by further dividing or combining together categories. In the process of classifying the papers, a paper could be identified with more than one category, which would provide a more comprehensive understanding of the distribution and features of the papers. As a result, eight categories in the dimension of research theme, six categories in the dimension of research method, and ten categories in the dimension of target subject for the analysis of HPS/NOS-related papers were established (Table 67.1).

When a paper was classified according to this category framework, the decision was made based on a wide consideration of not only its title or keywords but also its abstract, theme, aim, and results. Through this comprehensive process, it was found that HPS/NOS-related papers could be largely grouped into two groups: (a) researches which investigate or discuss “about” themes or theories related to HPS/NOS and (b) researches which applied ideas “based on” the results of HPS/NOS-related studies. All studies belonged to the former group, (a), were identified as HPS/NOS-related studies, whereas some belonged to the latter group were not identified as so. For example, if there is a study which investigated an effective instruction method for students’ conceptual change, it is ultimately related to HPS/NOS because instruction for conceptual change is too somehow related to philosophical arguments of science such as the nature of concept, constructivism, and knowledge development to some degree. If this kind of papers was included, in principle there would be no study which is not related to HPS/NOS. Thus, to avoid this situation, when making a judgment on papers of (b) kind, the paper was checked to see if it met the following criteria:

- Does this paper have explicit connects with HPS/NOS-related theories or concepts?
- Does this paper investigate how people think or perceive the nature of, not just simple interest in, science or scientific method or scientific concepts?
- Does this paper discuss explicitly target subject’s concept or the nature of their behaviors in terms of HPS/NOS, not just investigate their concepts or behavior?
- Does this paper make the participants or subjects to think about the nature of theories or concepts of science education and about theories or concepts related to HPS/NOS?

Table 67.1 Categories in each dimension

Dimension	Symbol	Categories
Theme	T1	Research on the trends of theories and ideas related to HPS/NOS
	T2	Research on history or historical episodes related to HPS/NOS
	T3	Research on concepts/terminologies and their nature related to HPS/NOS
	T4	Research on historical figures' life, works, and theory related to HPS/NOS
	T5	Research on social issues related to HPS/NOS
	T6	Research on curriculum and educational policies related to HPS/NOS
	T7	Research on participants' views and attitudes related to HPS/NOS
	T8	Research on instructional strategies, program, and textbooks related to HPS/NOS
Method	M1	Investigation of historical materials
	M2	Theoretical review
	M3	Quantitatively analysis on quantitative data
	M4	Quantitatively analysis on qualitative data (drawings, narrative answer, etc.)
	M5	Qualitative research
	M6	Experimental research
Participants/subject/objects	S1	Literature (published paper, historical materials, textbooks, etc.)
	S2	Kindergarten/primary students
	S3	Secondary students
	S4	University/Graduated students
	S5	In-service teachers
	S6	Experts (professor of science education, scientist, etc.)
	S7	Publics
	S8	Gifted students
	S9	Underachieve/disabled students
	S10	Facilities

– In case of studies which deal with instruction methods or programs, does this paper pay attention to their nature and change, rather than to obtaining scientific knowledge or to improving scientific skills?

67.3.2 Results of the Analysis

67.3.2.1 General Trend

Among a total of 1,362 papers published in JKASE between 1978 and 2010, the number of HPS/NOS-related papers was 246 which is 18.1 % of the total papers. Figure 67.1 shows the distribution of the HPS/NOS-related papers across the period.

As can be seen from Fig. 67.1, the number of HPS/NOS-related papers increased gradually until mid-2000s when the number started to decline slightly. However,

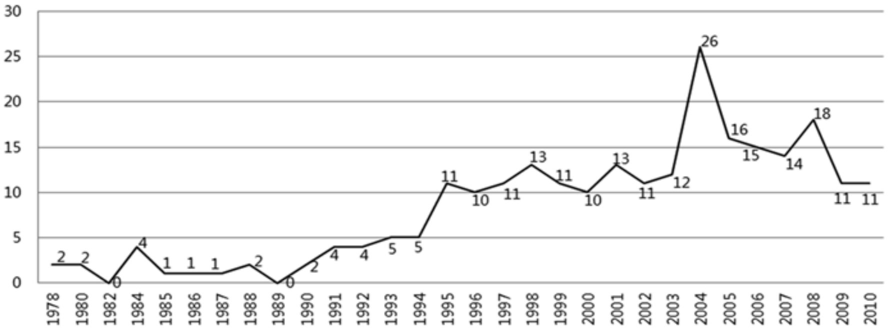

Fig. 67.1 Frequency of the papers related to HPS/NOS published in the JKASE

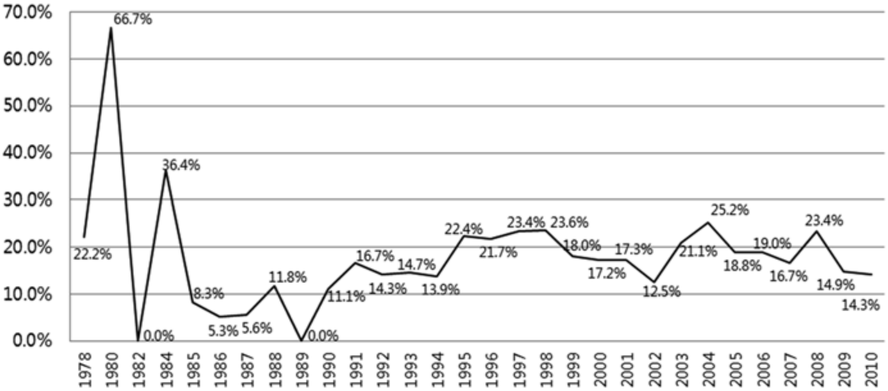

Fig. 67.2 Proportion of the papers related to HPS/NOS to the whole papers in the JKASE

since the number of total papers published by the journal itself has been increased (that is, 12 in 1978–1980, 24 in 1981–1985, 89 in 1986–1990, 171 in 1991–1995, 267 in 1996–2000, 408 in 2001–2005, 391 in 2006–2010), it is not appropriate to just compare the number of HPS/NOS papers over the periods. Figure 67.2 shows the percentage of HPS/NOS-related papers among the total papers published in JKASE in each year.

Based on Figs. 67.1 and 67.2, the proportion of HPS/NOS papers increased until the end of the 1990s, with the exception of the late 1970s and early 1980s when the total number of paper itself was very small. During this period of time when the proportion of HPS/NOS papers were increasing, Korea's 5th (1987–1992) and 6th (1992–1997) National Science Curricula were in practice. These National Science Curricula were based on the critical reflection of the previous National Science Curriculum in which too much emphasis was given to the discipline-centered approach and introduced the ideas of "Science for All" and STS in which not only scientific knowledge and process skills but also scientific attitudes and everyday scientific inquiry were emphasized at the level of the National Science Curricula (MEST, 2007a). It seems that these emphases of the National Science Curricula encouraged studies on the reconsideration of inquiry or concepts (e.g., Cho 1988; Cho 1990), on the needs and implementation methods of STS (e.g., Kwon 1991; Ha 1991; Cho 1991), and on the discussion and surveys of science-related attitude (e.g., Kwon and Park 1990; Hur 1993). In addition, following the first paper on constructivism in JKASE (Cho 1984), active research activities on the nature of science, scientific knowledge, scientific concepts, and scientific method (e.g., Cho 1988; Cho 1992) and on survey studies related to these aspects (e.g., Song and Kwon 1992; Kwon and Pak 1995) were carried out throughout the period. During the 1990s, there had been many empirical survey studies on NOS (e.g., Kwon and Park 1990; Song 1993), which made use of various newly developed instruments (such as, TOSRA, VOSTS, DAST, Nott & Wellington). The abovementioned trend during this time contributed to the growth of HPS/NOS-related papers during the 1990s.

The total number of authors of the 246 HPS/NOS-related papers in JKASE was 580, thus the average number of authors per paper was 2.4. Breaking down the period into three segments, the average author number was 1.5 during 1978–1990, 2.1 during 1981–1990, and 2.6 during 2001–2010. It is clear that the degree of co-studying for papers has been increased over time. Nevertheless, among the 580 authors of HPS/NOS-related papers, there were only 13 foreign authors, suggesting that the international collaborative research work has not been active.

Among the HPS/NOS-related papers, there were only 36 papers, i.e., 14.6 %, which were related to the history of science. Nevertheless, if we compare the numbers of history-related papers over the three decades, there was a noticeable increase: 1 paper during 1978–1990, 10 papers during 1991–2000, and 25 papers during 2001–2010.

67.3.2.2 Analysis Results of the Dimension of "Research Theme"

Table 67.2 shows the results of the analysis of the whole 246 HPS/NOS-related papers in terms of the dimension of research theme, whereas Fig. 67.3 shows the comparison of the results during the three decades.

Among the eight categories of the dimension of "research theme," the most popular one was "T7 Research on participants' views and attitudes related to HPS/NOS" with 43.9 % (i.e., a total of 108 papers). For example, like "Middle school science teachers' philosophical perspectives of science (Soh et al. 1998)" in which the authors found that the teachers predominantly held inductivistic views regardless of their major, gender, and career. Studies on students' and teachers' perceptions on the nature of science, philosophical aspects of science, STS, scientific attitudes, and science concepts occupied almost half of the HPS/NOS-related papers. Together with studies on "T8 Research on instructional strategies, program, and textbooks related to HPS/NOS" (22.8 %), this result indicates that studies on educational application and implementation of HPS/NOS were very popular. The second most popular category (27.2 %) was "T3 Research on concepts/terminologies and their nature related to HPS/NOS," suggesting that Korean science educators' attention has also been given to the

Table 67.2 Dimension of "research theme"

Symbol	Category	N	(%)	Example
T1	Research on the trends of theories and ideas related to HPS/NOS	12	4.9	Science education: constructivist perspectives (Cho and Choi 2002)
T2	Research on history or historical episodes related to HPS/NOS	14	5.7	Historical review in Foundation of London Loyal Society and France Loyal Academy (Kim 1978)
T3	Research on concepts/terminologies and their nature related to HPS/NOS	67	27.2	The role of deductive reasoning in scientific activities (Park 1998)
T4	Research on historical figures' life, works, and theory related to HPS/NOS	13	5.3	John Tyndall (1820–1894), who brought physics and the public together (Song and cho 2003)
T5	Research on social issues related to HPS/NOS	4	1.6	Brief discussion on the scientific creationism critiques (Yang 1987)
T6	Research on curriculum and educational policies related to HPS/NOS	25	10.2	An investigation into "Science-Technology-Society" curricula (Cho 1991)
T7	Research on participants' views and attitudes related to HPS/NOS	108	43.9	Middle school science teachers' philosophical perspectives of science (Soh et al. 1998)
T8	Research on instructional strategies, program, and textbooks related to HPS/NOS	56	22.8	The influence of small group discussion using the history of science upon students' understanding about the nature of science (Kang et al. 2004)
Total		299		

analysis and examination of existing theories or concepts related to HPS/NOS. For example, Park (1998) attempted to clarify the logical structure of the scientific explanation, prediction, and the process of hypothesis testing using syllogism and various concrete examples in his paper, "The role of deductive reasoning in scientific activities."

On the contrary, there were only small numbers of studies on social issues (1.6 %), on persons (5.3 %), and history or episodes (5.7 %) related to HPS/NOS. It would be quite natural that there were so many studies on the educational application or implementation of HPS/NOS in science education. However, too much emphasis on educational application could overlook the critical analysis of existing theories or perspectives and the suggestion of new theories or perspectives.

According to the comparison among the three decades (shown in Fig. 67.3), the proportions of T3 and T6 categories decreased, whereas the proportion of T8 category increased. In other words, studies on terminology/concepts/features of HPS/NOS became less popular, while those on instructional methods/programs/

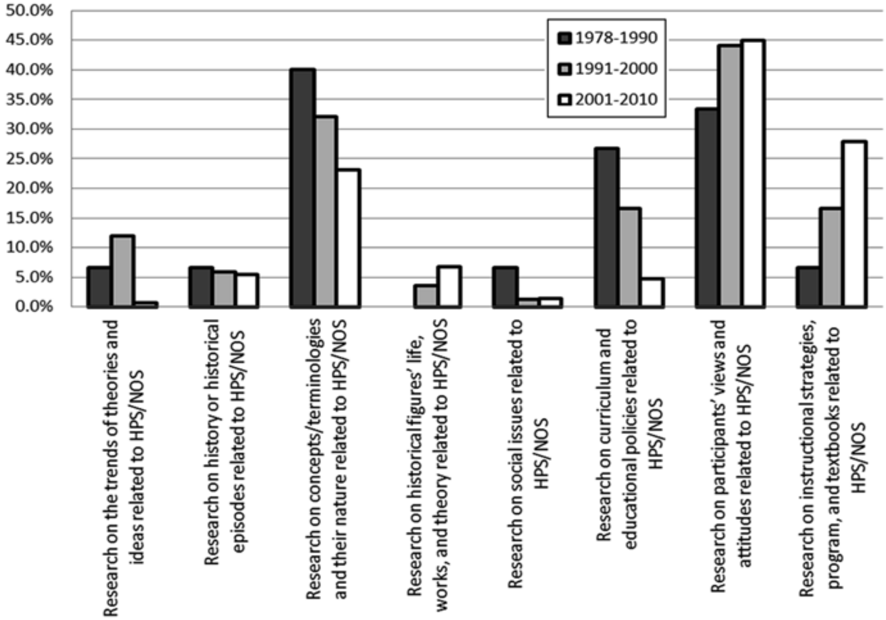

Fig. 67.3 Proportion of each "theme" to the whole HPS/NOS papers in three decades

textbooks became more popular. It seems that this trend reflects the history of Korean science education where in earlier years there were needs to carry out theoretical discussion and educational arguments for introducing HPS/NOS ideas, whereas after the 1990s there were needs to pursue more practical and concrete instructional methods and programs based on earlier more theoretical studies and on the introduction of the National Curricula emphasizing STS approaches and scientific literacy. This overall trend is also reflected in the very low proportion of "T1 Research on the trends of theories and ideas related to HPS/NOS" (only 0.7 %), like "Science education: constructivist perspectives (Cho and Choi 2002)" in which the authors described the characteristics of constructivism through reviewing the literatures from a few schools of constructivism, during the period of 2001–2010. Meanwhile, as discussed earlier, it is presumed that the continuous increase of "T7 Research on participants' views and attitudes related to HPS/NOS" was facilitated by the wide use of various newly developed instruments (such as, TOSRA, VOSTS, DAST, Nott & Wellington).

67.3.2.3 Analysis Results of the Dimension of "Research Methods"

Table 67.3 shows the result of the analysis of HPS/NOS papers in terms of research method, whereas Fig. 67.4 shows the comparison of the results during the three decades.

Table 67.3 Dimension of "research methods"

Symbol	Category	N	%	Examples
M1	Investigation of historical materials	20	8.1	The activity of an interpreter on science education during the enlightenment period in Korea: Focus on Hyun Chae (Park 2009)
M2	Theoretical review	92	37.4	A philosophical study on the generating process of declarative scientific knowledge: Focused on inductive, abductive, and deductive process (Kwon et al. 2003)
M3	Quantitative analysis on quantitative data	98	39.8	Teachers' and students' understanding of the nature of science (Han and Chung 1997)
M4	Quantitative analysis on qualitative data (drawings, narrative answer, etc.)	53	21.5	Teachers' images of scientists and their respected scientists (Song 1993)
M5	Qualitative research	18	7.3	An intensive interview study on the process of scientists' science knowledge generation (Yang et al. 2006)
M6	Experimental research	28	11.4	The effects of decision-making-centered STS (Science-Technology-Society) classes on the students' attitudes toward science and perceptions about STS (Hong 2001)
Total		309		

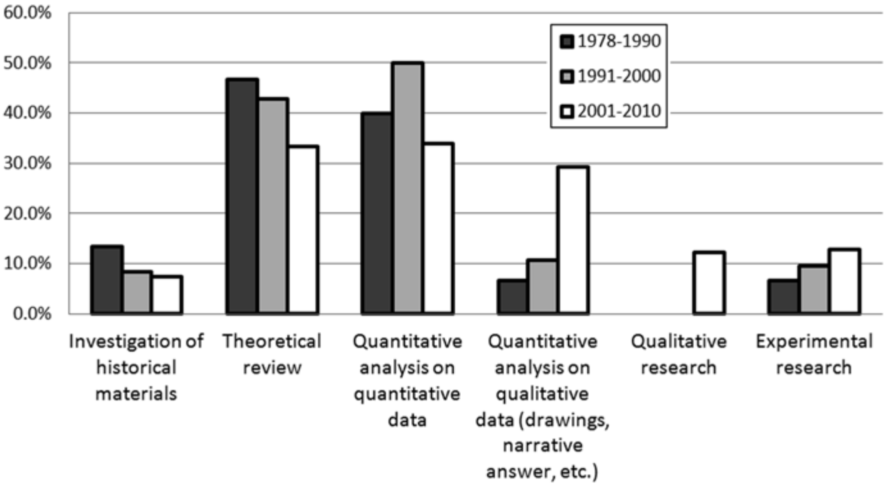

Fig. 67.4 Proportion of each "methods" to the whole HPS/NOS papers in three decades

Through the analysis of HPS/NOS-related papers in terms of research method, the most popular categories were “M3 Quantitative analysis on quantitative data” (39.8 %) and “M2 Theoretical review” (37.4 %). “M4 Quantitative analysis on qualitative data (drawings, narrative answer, etc.)” (21.5 %), exemplified by “Teachers’ images of scientists and their respected scientists (Song 1993)” in which the author explored through Draw-A-Scientist Test and analyzed the drawings with frequencies, was also relatively popular. On the contrary, “M1 Investigation of historical materials” (8.1 %) such as “The activity of an interpreter on science education during the enlightenment period in Korea: Focus on Hyun Chae (Park 2009)” and “M5 Qualitative research” (7.3 %) like “An intensive interview study on the process of scientists’ science knowledge generation (Yang et al. 2006a)” was not popular. This may illustrate that HPS/NOS-related studies in Korea during the last three decades focused more on reviews or analysis of existing relevant studies or with interpretation or investigation through the analyses of data (esp. quantitative). However, examining the trend along the timeline, a different picture of recent research methods becoming more diverse can be seen.

As shown in Fig. 67.4, recently, the two dominant methods (i.e., M2 and M3) became less popular, whereas M4 and M5 which included qualitative data and analysis became more popular especially during the 2000s. This trend of widening research methodology seems to reflect that from the 1990s Korean science education researchers began to pay attention to the weaknesses of quantitative research methods (e.g., for the investigation people’s understanding of the nature of science by Aikenhead and colleagues (1989)) and to advantages of more open and qualitative data analysis (e.g., Merriam 1988).

67.3.2.4 Analysis Results of the Dimension of “Research Subjects”

The results of the analysis of HPS/NOS-related papers in terms of the dimension of research subjects are shown in Table 67.4, whereas the comparison of the results during the three decades is shown in Table 67.5.

In terms of research subjects, the most popular categories were “S1 Literature (published paper, historical materials, textbooks, etc.)” (43.8 %) and “S3 Secondary students” (41.5 %). Conversely, the least popular categories were “S7 The general public” (1.2 %), “S9 Underachieving/Disabled students” (0.8 %), and “S10 Facilities” (0.8 %).

As shown in Fig. 67.5, as the subjects of the studies, teachers became less popular in the 2000s, whereas secondary students became much more popular from the 1990s. It is reasoned that this change was brought about by the increased research interest in students’ thinking and ideas influenced by constructivist approach from the end of the 1980s in Korea.

In case of “S8 Gifted students” like “The effects of explicit instructions on nature of science for the science-gifted (Park and Hong 2010)” in which the authors invited 20 science-gifted students as participants, there had been almost no studies until the 1990s, but then suddenly there was a sharp increase in the 2000s. This was mainly because that the Gifted Education Act was passed in 2000 and as a result,

Table 67.4 Dimension of "subjects/participants/objects"

Symbol	Category	N	%	Examples
S1	Literature (published paper, historical materials, textbooks, etc.)	108	43.8	The images of science education illustrated in the books written by modern philosophers of science (Song et al. 1997)
S2	Kindergarten/primary students	22	8.9	Perceptions about science and scientific activity of students in kindergarten and primary school (Kim and Cho 2002)
S3	Secondary students	102	41.5	Perception survey on characteristics of scientific literacy for global Science-Technology-Society for secondary school students (Ryu and Choi 2010)
S4	University/graduated students	29	11.8	Preservice science teachers' understanding of the nature of science (Nam et al. 2007)
S5	In-service teachers	29	11.8	A study on Korean science teachers' points of view on nature of science (Cho and Ju 1996)
S6	Experts (professor in science education, scientist, etc.)	8	3.3	Aims of laboratory activities in school science: A Delphi study of expert community (Yang et al. 2006)
S7	The general public	3	1.2	Science-related attitudes of Korean housewives (Kim et al. 2004)
S8	Gifted students	12	4.9	The effects of explicit instructions on nature of science for the science-gifted (Park and Hong 2010)
S9	Underachieving/disabled students	2	0.8	A investigation of the attitudes toward science and scientific attitude for the underachievers (Yi and Kim 1984)
S10	Facilities	2	0.8	Developing active role of science museum in educating on ethical issues on science and technology: Four case studies (Choi 2004)
Total		317		

government administrative and financial supports were put in place, such as establishing Gifted Education Institutions in universities and local education offices. This might show that studies related to HPS/NOS can also be influenced by national policies and governmental supports.

In sum, the analysis of HPS/NOS-related papers published in JKASE (*Journal of Korean Association for Science Education*) from 1978 to 2010 shows that HPS/NOS-related studies have been continuously carried out largely on HPS/NOS-related people's ideas/views/attitudes, on instructional methods or programs, and on terms/concepts/features of HPS/NOS. In general, although there has been some concentration on specific areas in terms of research method, research subjects, and purpose and results, recently research with diverse purposes and methods became more and more popular.

67.4 HPS/NOS in Textbooks in Korea

The science textbook is the most basic instructional material used in schools, particularly countries like Korea where school education is considerably centralized. Thus, the analysis of the content related to HPS/NOS in science textbooks would provide a good indication showing how much of HPS/NOS-related content are taught in schools. Existing studies on HPS/NOS content in textbooks (e.g., Cho 2008; Lee and Shin 2010; Leite 2002; Niaz 2000) also provide some meaningful references to this analysis. In this section, the analysis is done with the most recent science textbooks in Korea, which were published between 2009 and 2011 according to 2007 National Science Curriculum. It is expected that the results of the analysis illustrate the current practice of HPS/NOS-related instruction in Korean school science education.

67.4.1 The Method of Analysis

67.4.1.1 Textbooks Analyzed

This analysis was done with textbooks for G3 to G10 Science subject in Korea. The textbooks were written based on 2007 National Science Curriculum, except for G10 of which National Science Curriculum was revised once again in 2009. For G3 to G6 which are parts of elementary school years, there is only one kind of Science textbooks because there is a system of national textbooks for elementary schools in Korea (see textbooks of G3-1–G6-2 in the References). For G7 to G10 for which different kinds of Science textbooks are available through the government approval, the most two popular Science textbooks for each grade were chosen and analyzed (see textbooks G7-A–G10-B in the References).

67.4.1.2 Analysis Framework and Method

The content related to the history of science was analyzed based on the framework of Leite (2002). However, since in Korea there are no official student workbooks provided for G7 to G10 students and no separate lists of content according to learners' levels in science textbooks, it was not easy to use directly the analysis framework of Leite (2002). Thus, the frameworks of Choi, Yeo, and Woo (2005) and of Lee and Shin (2010) were consulted, which modified Leite's framework for better adjustment to Korean situation, and added some new items which were turned out to be necessary through the actual analysis. Tables 67.5, 67.6, 67.7, and 67.8 in the Sect. 67.4.2 show the framework for analyzing historical content of Korean science textbooks used in this study and the results.

There were four dimensions for analyzing historical content of the science textbooks: "Type and organization of the historical information" (see Table 67.5 in the

Table 67.6 Analysis of the content of the history of science

Sect. 67.4.2), “Content of history of science” (see Table 67.6 in the Sect. 67.4.2), “Source of history of science” (see Table 67.7 in the Sect. 67.4.2), and “Role of the historical content in science teaching and learning” (see Table 67.8 in the Sect. 67.4.2). The dimension of “Type and organization of the historical information” is to see what kinds of and how the historical information is treated in science textbooks and is consisted of two subdimensions: “Scientists” and “Evolution of science.” “Scientists” subdimension is divided further into two, “scientists’ life” and “scientists’ characteristics,” each of which is further divided into two or three items. The dimension of “Content of history of science” is to see the features of historical content in science textbooks and is consisted of three subdimensions – “Context to which historical information is related,” “Domain of science content,” and “Domain related to the purpose of science education” – each of which is divided further into several sub-subdimensions. The dimension of “Source of history of science” is to see the features of the sources of historical information and materials and is consisted of three subdimensions – “Materials used to present the historical information,” “Culture/Nations related to history of science,” and “Times related to history of science” – each of which is divided further into several sub-subdimensions. Lastly, the dimension of “Role of the historical content in science teaching and learning” is to see the actual roles of the historical content shown in textbooks in terms of science teaching and learning and is consisted of two subdimensions – “Fundamental” and “Complementary – each of which is divided further into several sub-subdimensions.

On the other hand, the content related to the philosophy of science or NOS was analyzed based on the framework of Choi, Choi, and Jin (2010). This framework is based on that of Leite (2002) but with a revision after considering VOSTS items in

in the framework of Choi, Choi, and Jin (2010), which earlier appeared in the framework for the content related to the historical content of science, were excluded. In addition, through the analysis of textbooks, it was found that there was a need to introduce a few new classifications and to make a slight revision of the framework. Tables 67.9 and 67.10 in the Sect. 67.4.3 show the framework used in this study to analyze textbook content related to the philosophy of science or NOS and the results.

The framework of analyzing philosophical/NOS content in science textbooks is consisted of 6 dimensions: "Responsibility and role of scientists" (see Table 67.9 in the Sect. 67.4.3), "Development of scientific knowledge" (see Table 67.9 in the Sect. 67.4.3), "Scientific methods" (see Table 67.9 in the Sect. 67.4.3), "Science-Technology-Society relation" (see Table 67.10 in the Sect. 67.4.3), "Domain related

to the purpose of science education" (see Table 67.10 in the Sect. 67.4.3), and "Role of the historical content in science teaching and learning" (see Table 67.10 in the Sect. 67.4.3). The dimension of "Responsibility and role of scientists" is to check the viewpoints of the textbooks describing scientists' roles and is consisted of two subdimensions: "Personal level" and "Social level." The dimension of "Development of scientific knowledge" is to check on what basis of the model textbooks describe the development of scientific knowledge and is consisted of two subdimensions: "Model of development" and "Introduction scope of 'development of science.'" The dimension of "Scientific methods" is to check the viewpoints of textbooks toward scientific methods and is consisted of four subdimensions: "Inductive method," "Deductive method (including the method of testing hypothesis)," "Abductive method (included in generating hypothesis)," and "Social consultation method." The dimension of "Science-Technology-Society relation" is to check whether textbooks describe the positive or negative relations among science, technology, and society and is consisted of three subdimensions: "Science-Technology relations," "Science-Society relation," and "Science-Technology-Society relation." The dimensions of "Domain related to the purpose of science education" and of "Role of the historical content in science teaching and learning" are consisted of the same subdimensions as earlier in the framework used for the analysis of historical content of textbooks.

For the analysis, the frequencies of items or sub-subdimensions were checked. If a part of a textbook dealt with one discovery or event or theme (either of the history of science or of the philosophy of science or NOS), it was counted as one occasion, regardless of the number of pages. In other words, two separate historical contents can be identified from a single page or more than one page can be regarded as dealing with a single historical content. On the contrary, in case of having two or more sub or sub-subdimensions or items in a single content related either to the history of science or to the philosophy of science/NOS, the frequency was counted as many as needed. The frequency was counted as a year total. That is, in the case of science textbooks for G3–G6 where there is only one kind of government-approved textbook, the frequency was calculated as a sum for two semesters. In the case of science textbooks for G7–G10 where the most popular two textbooks were analyzed, the frequency was calculated as an average of the sums of the two textbooks for two semesters.

67.4.2 Results of the Analysis of the Historical Content of Science Textbooks

Table 67.5 shows the results of the analysis of the type and organization of the historical content of Korean science textbooks for G3–G10.

As shown in Table 67.5, in the case of “scientists’ life,” the historical content of scientists’ life was mostly on biographical data (such as their names, years of birth, or death) which appeared with 81.5 cases, while the content on the episodes/anecdotes or personal characteristics of scientists was relatively very few appearing with 10.5 cases and 0.5 cases, respectively. This result is in accordance with the results of previous studies on Portuguese textbooks by Leite (2002) and on Korean textbooks based on the previous National Science Curricula by Choi and colleagues (2005) and by Lee and Shin (2010). This result shows that the descriptions of scientists tend to provide fragmented information, rather than meaningful narrative elements, of the scientists. Nevertheless, the appearance (i.e., 10.5 cases) of the episodes/anecdotes is in fact much higher than the result of the study by Lee and Shin (2010) which showed only 0.7 cases with the textbooks (for G3–G7) based on the 7th National Science Curriculum (MOE 1997). In fact, the elementary science textbooks (for G3–G6) based on the 7th National Science Curriculum had no appearance of episodes/anecdotes. The big increase of the episodes/anecdotes in the elementary science textbooks based on 2007 National Science Curriculum was made by introducing new sections, called “Science Stories” and “Inquiry by Scientists,” to the elementary science. These sections encouraged to have ample and diverse descriptions on scientists.

In the case of “scientists’ characteristics,” scientists were described in 15.5 cases as being of different characteristics – such as with full of curiosity and endless efforts to achieve exactness or with talented ideas – from ordinary people, while there was no description of scientists as ordinary people. For example, the process of which A. L. Wegener claimed the theory of continental drift and was searching for the grounds of his claim in a very rigorous way (G6-1, pp. 188–191) and the story of which Dr. Jangchun Woo (a famous pioneering Korean scientist) saved the people from the shortage of food through his talented ideas and enormous passion (e.g., G10-A, p. 294) are some examples of scientists as persons with exceptional abilities and attitudes. This kind of the description of scientists as exceptional abilities should be reconsidered, especially if we wish to encourage people's science-friendly attitudes and students' careen guidance toward science and engineering.

For "type of evolution" in "Evolution of science," the most common items described were "mention to a science discovery" (55 cases), "linear and straightforward" (35 cases), and "description of a science discovery" (22 cases), while "real evolution" and "mention to discreet periods" were only 4.5 cases and 6.5 cases, respectively. However, compared with that (i.e., 1.3 cases shown in Lee and Shin (2010)) of the science textbooks based on the 7th National Science Curriculum, "real evolution" became more popular, and this was also due to the introduction of "Science Stories" and "Inquiry by Scientists" sections. For example, the science textbook for the 2nd semester of G6 describes the whole process of the discovery of oxygen across its four pages, which includes A. L. Lavoisier's criticism to and experiment against J. Priestley's claim, discovery of the nature of air as the mixture of various gases, and the naming process of oxygen (G6-2, pp. 162–165).

In the case of "responsible people," the description of "individual scientists" (90.5 cases) was much more popular than those of "group of scientists" (19 cases) and of "scientific community" (14.5 cases), implying that historical content in the textbooks was largely focusing on the achievements of individual scientists.

Table 67.6 shows the analysis results of the content of the history of science. Popular contexts to which historical information is related were "scientific context" (52 cases), "technological context" (29.5 cases), and "social context" (8.5 cases), while "political context" and "religious context" were rarely or no described. The only "political context" was the case of the development of the Western calendar in which the role of the rulers is described as an important factor (G8-A, p. 351). Thus, in terms of the contexts, it can be argued that the textbooks still have rather narrow descriptions of the history of science, exclusively focusing on its scientific and technological contexts.

The analysis in terms of "Domain of science content" shows that the historical content was from "earth science" (46.5 cases), physics (31 cases), chemistry (26 cases), and biology (22.5 cases). Despite a higher ratio from "earth science," the distribution across the domains of science seems not to be overly biased. One thing to pay attention is that the vast majority of "biology" domain was from G10, 17.5 out of 22.5.

In the case of "Domain related to the purpose of science education," "cognitive domain" and "STS" were found to be most common, 87 cases and 42 cases, respectively, while "affective domain" and "process skill domain" were less common, 4 cases and 6.5 cases, respectively. This result with current science textbooks is rather similar to that of the result with previous science textbooks based on the 7th National Science Curriculum (Lee and Shin 2010) (that is, cognitive domain 96.7 cases, STS

16.9 cases, process skill domain 5.3 cases, and affective domain 1 case), except for the fact that "STS" became more popular. This result shows that although historical content can be effective in stimulating students' motivation, in illustrating humanistic aspects of science (e.g., Jung 1994; Matthews 1994) and in helping the understanding of scientific methods (e.g., Matthews 1992), the treatment of historical content in science textbooks is still biased toward its "cognitive" and "STS" aspects.

Table 67.7 shows the results of the analysis of "Source of History of Science" in terms of its materials form, cultural/national background, and historical period. The most popular forms of historical information were "texts by the textbook author(s)" (34.5 cases) and "scientists' pictures" (33 cases), such as M. Faraday, G. Galilei, and R. J. E. Clausius. On the contrary, original documents/texts were little used, as is seen in only 2 cases (e.g., the chemistry textbook and a part of element table by A. L. Lavoisier – G8-A, p.54). Despite the difficulty of the translation into Korean, for the credibility of historical information, it would be better to have more original documents/texts in science textbooks. On the other hand, in the case of photos and pictures of scientists, while there was no case in the elementary science textbooks (for G3–G6) based on the 7th Science Curriculum (Lee and Shin 2010), there were 14 cases in those based on 2007 National Science Curriculum, such as C. Alessandro Volta (G5-1, p. 86), L. Pasteur (G5-1, p. 166), and M. Faraday (G6-1, p. 182).

The "culture/nation" which had been the background of the history of science turned out to be overwhelmingly Western (in total 127.5 cases) compared with those from Eastern cultures (in total 17 cases). Furthermore, among those from Eastern cultures, 14 cases were Korean while the rest (3 cases) were from the rest of the Eastern region. This distribution, heavily biased toward the Western, would reflect the situation that most of school science content is in fact rooted into the Western science. It seems that this result is somehow related to the heavy emphasis on "cognitive domain" over "affective domain" in "Domain related to the purpose of science education" (see Table 67.7). That is to say, since the purpose of introducing of the history of science was mainly to help students' understanding of scientific concepts, it might have been natural to focus on the Western history which would be more directly linked with scientific concepts, rather than the Eastern history which would be more useful in terms of affective domains.

The analysis of "Times related to the history of science" shows that those of "contemporary times (20C-)" (56 cases) (e.g., stories of Apollo 8 & 11 (G8-A, p. 320), the development of solar cells (G10-A, p. 424)) and "modern times (17C–19C)" (53 cases) (e.g., Boyle's discovery of indicator (G6-1, pp. 62–63), and Lavoisier's naming of oxygen (G6-2, pp. 162–156)) were the most popular sources of the history of science. The high appearance of "modern times" is easily understood when it is noticed that the majority of school science content are on the historical developments of that particular period of the history. The appearance of "contemporary times" is in fact higher than that (38.4 cases (Lee and Shin 2010)) of the 7th National Science Curriculum, and this seems to be the result of 2007 National Science Curriculum's emphasis on scientific literacy (MEST 2007a, 2009).

Table 67.8 shows the result of the analysis of the role of historical content. The role of textbooks historical content in science teaching and learning was found to be slightly more frequently used as “Fundamental” than as “Complementary,” although the trend was reversed at the elementary school level especially for G3–G4.

As indicated in Tables 67.5, 67.6, 67.7, and 67.8, for the most part, science textbooks for G10 appear to have much more historical content than those for other grades. This is because science textbooks for G10 were developed on the basis of the most recent curriculum, 2009 National Science Curriculum, which emphasizes the improvement of students’ scientific literacy through various materials for the teaching of meanings, values, and roles of science instead of fragmented knowledge of each discipline of science.

67.4.3 Results of the Analysis of the Philosophy of Science/NOS-Related Content

The analysis of the philosophy of science/NOS content of Korean science textbooks for G3–G10 resulted in a variety of dimensions and subdimensions. The results of the analysis for “Responsibility and role of scientists,” “Development of scientific knowledge,” and “Scientific methods” are shown in Table 67.9.

For the “Responsibility and role of scientists,” the “personal level” (29.5 cases) was found to be more popular than the “social level” (22 cases). However, at the elementary level, the trend was reversed. In elementary science textbooks, 21 cases of the “social level” were presented while 12 cases of the “personal level.” For example, there was a great deal of content on the social roles and responsibility of scientists, such as, the story of Jane Goodall’s study of chimpanzees. Jane Goodall’s study was described in details in conjunction with the activities of environmental and animal protection groups (G3-2, pp. 66–67). Another example was a description of the beneficial contributions of scientists to the development of artificial internal organs based on their knowledge on human body (G5-2, p. 54). Once again, this increase illustrates the effect of introducing the sections for “Science Stories” and “Inquiry by Scientists” in 2007 National Science Curriculum.

In the case of “Mode of development” of the “Development of scientific knowledge,” the “cumulative model” (15.5. cases) was found to be most common, followed by “evolutionary model” (8 cases), “gradual model” (8 cases), and “revolutionary model” (3 cases). This bias toward the “cumulative model” of scientific knowledge development can be an obstacle in introducing the diverse and complicate nature of scientific knowledge. Nevertheless, considering the result of the previous study by Choi and colleagues (2010) with science textbooks based on the previous 7th National Science Curriculum showing that “cumulative model” was 89.1 % and that there was no description on the model of scientific knowledge development in elementary science textbooks, it is a remarkable improvement. In addition, the current science textbooks include many more cases of “introduction of scientific developments with the background and consequences of them” (26 cases) than those of “introduction of scientific developments only” (8 cases).

In the case of "Scientific methods," "Deductive method (including the method of testing hypothesis)" (34 cases) and "Inductive method" (30.5 cases) were found to be much more popular than "Social consultation method" (1.5 cases). The extremely low description of "Social consultation method" illustrates well how current science textbooks overwhelmingly adapt traditional models of scientific development. Nevertheless, considering the result of Choi and colleagues (2010) in which, with no classification of "Abductive method (included in generating hypothesis)," "Inductive method" (84.5 %) was the vast majority compared with "Deductive method (including the method of testing hypothesis)" (15.5 %) and "Social consultation method" (no case), it can be said that the current science textbooks adapt more diverse views of scientific development. This tendency can also be found in the fact that there were 21 cases of the descriptions on "Abductive method (included in generating hypothesis)." In the case of "Abductive method (included in generating hypothesis)," the cases in which the process of abductive inference (Peirce 1878) based on similarity were mentioned or in which students were guided to have tentative explanations after observation activities were counted.

Meanwhile, in contrast to the situation that there had been no description on scientific method in the previous elementary science textbooks based on the 7th National Science Curriculum (Choi et al. 2010), the current elementary science textbooks contain 47 cases of descriptions on scientific method. It is presumed to be caused by the 2007 National Science Curriculum's introduction of "Free Inquiry" in which students are expected to carry out their own long-term investigations and thus to have experience of choosing inquiry topics, selecting inquiry methods, transforming inquiry data, and reporting inquiry results (MEST 2007a). Together with "Science Stories" and "Inquiry by Scientists," the introduction of "Free Inquiry" encourages the description of scientific methods.

Table 67.10 shows the result of the analysis of "Science-Technology-Society relation," "Domain related to the purpose of science education," and "Role of the NOS content in science teaching and learning."

For "Science-Technology-Society relation," there were 10.5 cases of "Science-Technology relation," 7 cases of "Science-Society relation," and 17 cases of "Science-Technology-Society relation." Among them, while the cases of the first two were only positive ones, 1.5 cases out of the 17 cases of the third were negative ones, such as "… the development of industry and the growth of population demand more fresh water. However, due to the environmental destruction and water pollution, the amount of usable water decreases and thus we are making a great deal of efforts to secure the water resource. We need water conservation" (G4-1, p. 125).

For "Domain related to the purpose of science education" which was further classified according to the major purpose areas stated in the 2007 National Science Curriculum, 39 cases of "cognitive domain," 30.5 cases of "process skill domain," 24.5 case of "STS," and 5.5 cases of "affective domain" were identified. Compared with that with historical content (6.5 cases), the number of cases of "process skill domain" with philosophical content/NOS here, i.e., 30.5 cases, is much higher. This is thought to be caused by the introduction of "Free Inquiry" activities in the 2007 National Science Curriculum (MEST 2007a).

For “Role of the NOS content in science teaching and learning,” there were 47.5 cases of “Complementary” which is much higher than that of “Fundamental.” This tendency was more apparent with lower grades, implying that philosophical content/NOS descriptions are treated of more importance with higher grade students.

In sum, in Korean science textbooks for G3 to G10, the historical and philosophical/NOS content is still represented with a bias in areas like the descriptions on scientists, the evolution of science, the sources of historical materials, the developmental model of scientific knowledge, scientific methods, and the roles in science teaching learning. Nevertheless, as the new 2007 (or 2009) National Science Curriculum introduced new sections like “Science Stories,” “Inquiry by Scientists,” and “Free Inquiry,” new science textbooks emphasized scientific literacy and inquiry activities and thus included more frequent and diverse descriptions of the history of science and the philosophy of science/NOS-related aspects.

67.5 HPS/NOS in Teacher Education Programs in Korea

The practice of education is heavily depending on teachers’ actions. Thus the professional development of teachers must be one of the most important elements of improving the quality of education. The teachers’ professionalism includes the speciality in teaching methods (Shulman 1987) and the specific abilities required in school practice (Castetter 1986). The professional development of teachers is considered as the starting point of a systemic innovation of education (Desimone et al. 2002; Seo et. al. 2010; Smith and O’day 1991), and the quality of science education depends on the professionalism of teachers who teach science. The professional development of teachers needs to be considered at the two different levels, preservice and in-service levels. In this respect, HPS/NOS-related practice of teaching science can also be examined with preservice as well as in-service teacher programs. Thus, this section will analyze the programs related to HPS/NOS for preservice and for in-service teacher education programs and investigate the efforts to improve the HPS/NOS-related teachers’ professionalism.

67.5.1 The Method of Analysis

67.5.1.1 Programs Analyzed

The analysis of the ratio of HPS/NOS-related preservice programs was done with the curricula of national universities. In Korea there are ten National Universities which provide preservice teacher education programs for secondary science and ten National Universities of Education which provide preservice teacher education programs for elementary science.[2] These universities are scattered evenly across the nation and thus provide a good representation of the nationwide situation.

The analysis of the ratio of HPS/NOS-related in-service programs was made with the programs provided by eight major Offices of Education (of seven metropolitan cities and one province) among sixteen regional Offices of Education. Among the eight, Offices of Education in Seoul and in Gyeonggi Province cover nearly a half of the total population of the nation, while the remaining six Metropolitan Offices of Education are scattered across the nation.[3] Therefore, the in-service programs of the eight major Offices of Education provide a good representation of the whole nation.

67.5.1.2 Analysis Method

The analysis of preservice programs was carried out with the curriculum information shown on the universities' home pages in 2011. The titles and credits of the courses which appeared to be HPS/NOS-related were identified, and the ratios of the credits of the courses out of the total credits for a successful completion of the degree (i.e., B.Sc.) were calculated. Since the information used in the analysis was obtained from university home pages, the actual practice in the universities might be somewhat different from the data obtained in this study.

Similarly, the analysis of in-service programs was carried out based on the information obtained from the home pages of the Offices of Education. Generally, there are two kinds of in-service programs: one conducted directly by the Office of Education or its official in-service training institution and the other conducted usually by schools or teacher associations or private sectors. While the former is listed in the science education plan of the Office of Education, the latter is often classified as the specialized institutions' in-service programs. For each Office of Education, the whole in-service programs were first checked, and among them science programs and HPS/NOS-related programs were identified based on their titles. During this process, in order to focus on science or science education programs, programs for teachers' general qualifications, gifted education, environment, invention, and visiting from domestic or foreign universities were excluded.

Offices of Education provide the information of their in-service programs with different levels of classification, some with broader classifications while others with narrower classifications. Thus it would be impossible to directly compare the numbers of programs provided by different Offices of Education. As a result, the analysis of HPS/NOS-related in-service programs in this session is sensible only in terms of ratio compared with the whole programs of a particular Office of Education and any comparison in terms of its number between Offices of Education would be meaningless.

---

[2] The names and URLs of the National Universities and of the National Universities of Education are listed in the Appendix.

[3] The names and URLs of the eight Offices of Education are listed in the Appendix.

Table 67.11 Titles and credits of HPS/NOS-related courses in the curricula of National Universities in Korea

Total	1421		3.5

[a] The ratio of the credits of HPS/NOS-related courses to the total required credits for graduation

67.5.2 Results of the Analysis of HPS/NOS-Related Preservice Teacher Education Programs in Korea

Table 67.11 shows the ratios of the credits of HPS/NOS-related courses in the ten National Universities which provide preservice teacher education for secondary science.

As seen in Table 67.11, all ten National Universities which provide preservice teacher education for secondary science offer some sorts of HPS/NOS-related courses, such as “History of Science for Teachers,” “Philosophy of Science for Teachers,” and “History of Physics and Philosophy of Science.” However, about a half of the universities offer only one course of two or three credits. Only three of them offer three or more HPS/NOS-related courses. The average ratio of the credits of HPS/NOS-related courses to the total required credits for graduation was only 3.5 %. Although as seen earlier HPS/NOS-related papers and content in textbooks increased over time, teaching of HPS/NOS in preservice teacher education seems still not to be popular. This tendency is even more apparent in National Universities of Education, as shown in Table 67.12.

As shown in Table 67.12, only four National Universities of Education offer HPS/NOS-related courses, and among the four three offer only one course of two credits.

Table 67.12 Titles and credits of HPS/NOS-related courses in the curricula of National Universities of Education in Korea

University	Credits for graduation	Titles of HPS/NOS-related courses (credit)	%[a]
A	140	–	–
B	144	–	–
C	152	Science in Life and in History (2) Understanding Earth Science with History (2)	2.6
D	140	–	–
E	145	–	–
F	145	History of Science (2)	1.4
G	145	History of Science (2)	1.4
H	145	–	–
I	147	History of Science (2)	1.4
J	145	–	–
K	150	–	–
Total	1448		1.9

[a] The ratio of the credits of HPS/NOS-related courses to the total required credits for graduation

In sum, the average ratio of credits of HPS/NOS-related courses to the total required credits for graduation was only 1.9 %. Furthermore these courses are only optional, not mandatory. For example, in "G" National University of Education, there are 12 departments and only about a half of the students of science education department usually take the course of History of Science, implying that only about 5 % of the students of G National University of Education take the course of History of Science. Although this analysis was only based on the information shown at the universities' home pages, which might be quite different from their actual practice, and some HPS/NOS-related content can be taught in more general courses like "Theories of Science Education" or "Methods of Teaching and Learning of Science," the fact that only less than a half of the universities offer HPS/NOS-related courses clearly shows that the teaching of HPS/NOS in Korean National Universities of Education is very limited.

Tables 67.13 and 67.14 also show that the provision of HPS/NOS-related in-service programs is also extremely limited.

As shown in Table 67.13, out of a total of 130 programs appeared in the in-service training plans for science education of the eight Offices of Education, there were 72 science-related programs, and among them "History of Science for Teachers," provided for 32 teachers schedules for 15 h, was the only program related to HPS/NOS. Similarly, out of a total of 2083 programs in special institutions' in-service training programs provided by the Offices of Education, there were 81 science-related programs, and among them "Teaching Practice of Science Ethics Lessons," provided for 25 teachers scheduled for 30 h, was the only program related to HPS/NOS. Even considering the possibility that there would be some more programs which would include HPS/NOS-related content or activities, the HPS/NOS-related content or activities in Korean preservice as well as in-service teacher education programs are very much limited.

Table 67.13 HPS/NOS-related programs appeared in the in-service training plans for Science Education of Offices of Education

Office of Education	Number of the total in-service programs[a]	Number of science-related in-service programs	Number of HPS/NOS-related in-service programs (title, target group, participants, hours)	Year
A	42	18	1 (History of Science for Teachers, Secondary Science Teachers, 32 persons, 15 h)	2011
B	17	4	–	2011
C	16	12	–	2010
D	9	9	–	2011
E	14	8	–	2011
F	15	9	–	2011
G	4	3	–	2011
H	13	9	–	2008
Total	130	72	1	

[a] Since each Office of Education provides the information of its in-service programs with a different level of classification, it would be meaningless to compare the numbers of the programs provided by different Offices of Education

Table 67.14 HPS/NOS-related programs in special institutions' in-service training programs provided by offices of education

Office of Education	Number of the total in-service programs[a]	Number of science-related in-service programs	Number of HPS/NOS-related in-service programs (title, target group, participants, hours)	Year
A	1144	54	–	2011
B	160	7	1 (Teaching Practice of Science Ethics Lessons, K-12 Teachers, 25 persons, 30 h)	2011
C	111	1	–	2010

E	264	5	–	2011
F	186	9	–	2010
G	55	1	–	2011
H	103	2	–	2011
Total	2083	81	1	

[a] Since each Office of Education does or does not provide the information of its in-service programs done by special institutions, it would be meaningless to compare the numbers of the programs provided by different Offices of Education

67.6 Conclusion

In this chapter, the status quo of HPS/NOS-related aspects of Korean science education was outlined. To do this, the historical changes of Korean National Science Curricula were summarized. Then the change of research trends of science education by analyzing the HPS/NOS-related papers published in JKASE for the last three decades was examined. After that the HPS/NOS-related aspects in science textbooks and in the programs of (preservice and in-service) science teacher education were analyzed.

Since the middle of 1980s, science in Korean National Curriculum began to have more of concrete and expressive descriptions related to HPS/NOS. The 5th National Science Curriculum announced in 1987 included "scientific literacy" as one of its major objectives, while the 6th National Science Curriculum announced in 1992 emphasized STS-related content and instruction methods. 2007 National Science Curriculum included once again "scientific literacy" as its one of major objectives and suggested to use materials related to scientists, the history of science, and to science-related or socio-scientific issues.

The analysis of the papers published in *Journal of Korean Association for Science Education* (the most representative academic journal of the field) for the last three decades shows that there has been a continuous substantial body of HPS/NOS-related studies on the areas, such as HPS/NOS-related recognition and ideas, instruction methods or programs, and the nature and features of terms or concepts. Although in general science education research in Korea has been more inclined to some specific areas (such as, quantitative studies, review studies, studies on students' or teachers' HPS/NOS-related perceptions or attitudes), recently studies with more diverse research purposes or methods or new perspectives or new theories became more popular.

The HPS/NOS-related content in Korean science textbooks for G3–G10 appeared to be biased in areas like the descriptions of scientists, the evolution of science, material of historical content, scientific method, and the developmental model of scientific knowledge and in terms of the purposes or roles in science education. However, the newly introduced sections (such as "Science Stories," "Inquiry by Scientists," "Free Inquiry") in the 2007 National Science Curriculum encouraged more and diverse HPS/NOS-related content in the textbooks.

The analyses of the HPS/NOS-related courses or programs in preservice and in in-service teacher education programs showed that there is a need to have more programs related to HPS/NOS both in preservice as well as in-service programs.

Based on the findings of the analyses reported in this paper, the following implications to Korean science education can be made.

Firstly, there is a need to have a continuous emphasis and concrete guidelines for HPS/NOS in the National Science Curriculum. As we have seen in the analyses of research papers in *JKASE* and of science textbooks, the National Science Curricula have played important roles in encouraging relevant studies and in including related content in textbooks. Especially, in a nation like Korea where a centralized education system is firmly placed, the inclusion and concrete descriptions of HPS/NOS aspects in the National Science Curriculum are vitally important in bringing real changes in research activity, in textbook content, and in teacher education programs. Although this cannot be the sufficient condition, it would be a necessary condition or an effective way for the actual change.

Secondly, there is a need to apply a wide range of methods and tools of research. As seen earlier, HPS/NOS research activities in Korea have been influenced by the available research methods and tools of the time. For example, the increase of studies on students' or teachers' perceptions or attitudes around the 1990s was possible by applying newly developed tools like TOSRA, VOSTS, DAST, and Nott and Wellington's. On the other hand, the increase of qualitative studies in Korea was affected by the worldwide trend of qualitative studies. Recently, Lederman (2007) began to combine the NOS survey tool with the qualitative approach, thus is expected to produce more comprehensive research results. In addition, since research results are influenced by their sociocultural backgrounds, the development of research tools, especially revised or newly developed in connection with Korean sociocultural context, would provide more meaningful and comprehensive results for HPS/NOS-related studies.

Thirdly, there is a need to develop and to put into practice more HPS/NOS-related programs for preservice and in-service science teachers. HPS/NOS-related programs for preservice and in-service science teachers in Korea have been insufficiently provided, especially for elementary science teaching. According to the study of Lee and Shin (2011) which carried out a survey with specialists of science education and of the history of science, the most common responses to "why is the history of science not used actively in schools?" were "no sufficient appropriate materials for teachers in schools," "teachers' ignorance of how to use the history of science," "no proper preservice education programs for the usage of the history of science," and "no proper in-service training programs for the usage of the history of science." In order to have more active teaching and learning of HPS/NOS in school education, not only its emphasis in the National Science Curriculum and in science textbooks, the development and implementation of HPS/NOS-related preservice and in-service programs are needed.

Fourthly, there is a need to have comparative studies across nations. Although in this chapter the findings of National Science Curricula, science textbooks, and teacher education programs of Korea were loosely compared with related international trends, the discussion was very limited due to the lack of the authors' understanding and information of the world trend and cases of other nations. Further studies addressing this comparative analysis are in need. In particular, regions in East Asia where much of the educational system and school practice is shared would be the easiest and should be the first area to be targeted in this kind of comparative studies.

Finally, there is a need to develop the collaboration between the communities of science education and science studies. HPS/NOS is the very area where the two (or more) different academic communities need to work closely. However, it is in fact true that the two different communities have rarely shared their expertise and experience. Perhaps like in many other countries, in Korea, many of science educators frequently refer to the theories and concepts of the history, philosophy, and communication of science but with little relevant professional training, while the historians and philosophers of science have strong interest in science education but with no relevant experience. Together with today's great demands for informal science education, PUS (public understanding of science), and science culture, the active communication and collective efforts between the two communities are called for more than ever before. In this respect, the activity of IHPST (International History, Philosophy, and Science Teaching group) and its regional activities (like 2012 IHPST Asian Regional Conference) are with high expectations.

In this chapter, the authors focused on describing the recent and current situations of HPS/NOS-related aspects in Korean science education. Thus, due to some practical reasons, it was inevitable not to discuss the issues in depth and to cover the whole range of related issues. Despite all these limits, it is hoped that this chapter will help the readers to better understand some aspects of Korean science education, in particular those related to HPS/NOS.

Acknowledgement The authors of this chapter wish to thank Jinsun Park, a doctoral student of Seoul National University, for her kind help in analyzing the data reported here.

Jinwoong Song is a Professor at the Department of Physics Education, Seoul National University, Korea. He took his BA in physics and MEd in science education at Seoul National University and received Ph.D. in science education at King's College London (1990). In addition to his previous position at Daegu University, Korea, he had opportunities to work as a visiting academic to King's College London, Institute of Education, and the University of Oxford. He served as the editor in chief of *Journal of the Korean Association for Science Education*, as the president of EASE (*East-Asian Association for Science Education*) (2009–2011), and more recently as the chair of the organizing committee of the First IHPST Regional Conference in Asia held on 18th–20th October, 2012, at Seoul National University, Korea. His research interests cover a wide range of topics in science education, including the contextual dimension of physics learning and teaching, informal science education, socio-scientific issues, science culture, the history of science education, and linking HPS with science education.

Yong Jae Joung is an Assistant Professor of Gongju National University of Education, Korea. He received his Ph.D. in science education from the Seoul National University and was a postdoctoral research fellow, 2006–2007, at Monash University. His research interests include the nature of science and scientific methods in science education, conceptual learning of science with philosophical views, and the relationship between individuals and community in science learning. Some of his recent published papers are Y. J. Joung (2008) Cases and features of abductive inference conducted by a young child to explain natural phenomena in everyday life, *Journal of Korean Association for Research in Science Education*; Y. J. Joung (2009) Children's Typically-Perceived-Situations of floating and sinking, *International Journal of Science Education*; Y. J. Joung, & R. Gunstone (2010) Children's Typically-Perceived-Situations of force and no force in the context of Australia and Korea, *International Journal of Science Education*; and H. –G. Yoon, Y. J. Joung, & M. Kim (2012) The challenges of science inquiry teaching for preservice teachers in elementary classrooms: difficulties on and under the scene, *Research in Science Education* (Online First article).

Chapter 68
History and Philosophy of Science in Japanese Education: A Historical Overview

Yuko Murakami and Manabu Sumida

68.1 Precursors

68.1.1 Science and Technology in the Edo Period

68.1.1.1 Under the Isolation Policy

Japan developed its own science and technology during the Edo period (1600–1867). At the time the government countered colonization efforts by Christian ministries by adopting a policy of national isolation (1633–1854) and by banning Christianity (1587–1858). Diplomatic ties were, however, continued with Korea, the Netherlands, and China. Such ties were nonetheless still regulated by the government. Some translators did manage, though, to import scientific knowledge from the Western world. For example, the Dutch version of Johan Adam Kulmus's *Anatomische Tabellen* was translated into Japanese (1774) with illustrations by Odano Naotake (1750–1780).

Scholars are still examining the philosophical foundations of science in the Edo period. Some principal figures in scientific thought in the period include Arai Hakuseki and Miura Baien. Tsuji (1973) points out the roles of neo-Confucianism combined with rationalism in shaping the nature and practical emphasis of Edo science where articulating the laws of nature was connected to social justice. Nakayama (1977), by contrast, argues that the influence of Chinese thought on the understanding of

e-mail: msumida@ed.ehime-u.ac.jp

M.R. Matthews (ed.), *International Handbook of Research in History, Philosophy and Science Teaching*, DOI 10.1007/978-94-007-7654-8_68,

scientific laws was political: if observation did not fit a theory, it was considered an omen requiring governmental response. There is thus no consensus on the influence of Confucianism upon Japanese science.

Research in astronomy, initially imported from China, was conducted to develop the locally adjusted calendar system for Japan. Shibukawa Harumi became the first official astronomer in 1685 responsible for a Japanese calendar. The astronomy office dealt with the importation of all scientific knowledge, including maps and translations from the Dutch. This office became the Bansho Torishirabesho, one of the origins of the University of Tokyo.

Wasan, or Japanese mathematics, was developed independently from Western mathematics. Seki Takakazu (1642–1708) discovered differentiation and developed an equivalent of Bernoulli numbers, an approximation of pi, and trigometric functions.[1] Wasan was widely accepted in Japanese society before the Meiji restoration as a form of entertainment. People from various social classes donated wasan problems to temples and shrines.

Interest in wasan reflected the notable literacy rate of the Edo period even in the general public. It is said that 50 % of males and 20 % of females were literate nationwide in late Edo period. Generally speaking, the public was eager to learn to read and write and to perform basic calculations with an abacus. Literacy of this kind was facilitated by thousands of small private schools open to the general public.

Almost everyone in the Samurai class was literate. The government operated various kinds of schools for elites. Shoheizaka Gakumonsho in Edo (current Tokyo) was the main school, which aimed to teach Confucianism. It later developed into the Kaiseisho, which in turn merged with the University of Tokyo. There were also schools for the study of China, medicine, and foreign languages. Each local government also had a school. Altogether there were 270 governmental schools in the late Edo period.

68.1.1.2 Tension Between Nationalists on Science and Technology

Discussion on Japanese isolation ended when war vessels of Russia, the British Empire, France, and the United States approached Japan (1787–1854) to negotiate unilateral treaties, forcing Japan to open its borders. Nationalists argued for “Western technology with the Japanese mind (和魂洋才),” while advocates for opening the country coined the slogan “Secede from Asia and join Europe (脱亜入欧).” Both parties recognized that Western technology and scientific knowledge were the keys to avoiding colonization and maintaining national independence. The tension between nationalists who favored isolationism and those who insisted on opening the country continued for a long time.

---

[1] Research on the meaning of wasan is ongoing. The concept, to date, has been largely misunderstood. For example, some argue that wasan lacks the notion of functions (Ueno 2006).

68.1.1.3 Technology Transfer from Europe Around the Meiji Restoration (1862–1880)

Western technology was imported to some regions in the end of Edo period. Satsuma (current Kagoshima area) introduced British cotton and sugar industries, for example. Technology transfer was extended after the Meiji restoration (1868). The Japanese government then took steps to import Western technology and scientific knowledge.

The foundation for a strong emphasis on engineering was laid by a younger generation that studied abroad before the restoration, such as the "Choshu five," five young samurais who left Japan illegally in 1862 and smuggled themselves to England in 1863. Kido Takayoshi, who was one of the main actors of the Meiji restoration and later became an important figure of the new government, supported their travel. Jardine Matheson & Co. arranged their stay in London. They first learned English and then began studying in the University College of London. Among the five students, Ito Hirobumi and Inoue Kaoru went back to Japan earlier than the other three when Choshu's fight against Europe was reported on a newspaper in 1864. They became important figures in the new government: Ito Hirobumi became the first minister of industry in 1876; and Inoue Kaoru became the second minister of industry. The other three continued their study in England. Endo Kinsuke followed them due to health problem in 1866. Inoue Masaru learned railroad systems in London. Yamao Yozo, interested in shipbuilding, moved from UCL to Glasgow. He worked at Napier shipbuilding in the daytime and studied at Anderson College at night. He met Henry Dyer there, who later came to Japan where he became the first chairperson of the new school of industry. Yamao and Inoue were called back to Japan in 1868.

It was not only Choshu who sent students abroad. Satsuma sent 19 students to England in 1865 with full financial support from the Satsuma feudal government. The Edo government also sent 17 students to study abroad with Enomoto Takeaki as its leader; he later became an admiral. Most of the students were naval cadets, but Nishi Amane and Tsuda Mamichi received training in law and political science in the Netherlands. They left Edo in 1862 and arrived at Rotterdam in 1863. Nishi and Tsuda went to Leyden and attended lectures of Simon Vissering and Cornelius Willem Opzoomer. They went back to Japan via Paris in 1865, where they met other intellectuals and the future political leaders of Japan. One of them was Mori Arinori, who later became the first minister of education in the Meiji government.[2]

After their arrival, Nishi and Tsuda were assigned to Kaiseisho, the main school of the Edo government. Kaiseisho merged with the University of Tokyo after the Meiji restoration. Nishi and Tsuda became government officers and translated many academic books as well as developing their own original philosophy. It was a critical time for Japan to integrate Western ideas to the native Japanese framework of thought. The words "Kagaku" and "Tetsugaku" were coined by Nishi to mean "science" and "philosophy."

---

[2] See Piovesana (1963).

"Kagaku" is most widely used as a general term for "science." The word "Kagaku" literally means "section-study," which reflected the Western propensity to develop specialized scientific fields in the late-nineteenth century. The literal meaning may even have precipitated sectionalism in the development of science and technology in Japan.

The word "science" is currently translated into four different words, "gakujutu," "kagaku," "rika," and "rigaku." "Gakujutu" is almost similar to academic activities or the Latin word *scientia*. "Kagaku" can be paralleled with "shakai" (society) or "gijutu" (technology) as general terms, where "rika" and "rigaku" sound inappropriate. "Rika" is currently used for the name of subject in elementary and secondary education, while "rigaku" is used for the academic area of natural science in higher education in the same level as "kogaku" (engineering) or "hogaku" (legal science). A difference is that "rigaku" often includes mathematics, while "rika" does not. "Rika" as an academic subject covers physics, chemistry, geology, and biology.

The word "rika," however, appeared first as the name of an academic field in the same level of "bunka" (humanities) and "ika" (medical), the same as the current use of "rigaku." Thus, "Rika Daigaku" meant the college of science in the early modern period of higher education in Japan. The first Education Law (教育令) (1879) specified physics, physiology, and natural history as optional subjects, i.e., the word "rika" appeared only to indicate one of specialized areas in higher education.

The word "rika" was then introduced into primary and secondary education in an 1886 ordinance of ministry of education (Ministry of Education 1986) following an 1885 amendment to educational law. The ordinance was the first official curricular guideline, and it specified "Rika" as an educational subject in upper elementary school. The contents were not explicitly stated, but the emphasis was placed on scientific phenomena in everyday life.

Such multiple meanings for the Western term "science" are indicative of the conceptual struggles at stake in adapting ideas and concepts from the Western world in Japan.

68.2 Science and Technology in the Meiji Period

68.2.1 Institutionalization of Education in Science and Technology

After the Meiji Restoration (1868), the new government was eager to introduce Western science and technology in order to maintain national independence in an age of imperialism. This decision was for the most part successful, but it neglected NOS.

The ministry of education was established in 1870. In 1871 it announced a plan for 4-year lower elementary schools, 4-year higher elementary schools, middle schools, and universities. Despite the ambitiousness of their plan, only elementary schools were inaugurated, with the number of schools growing to 26,000 within a few years. Although the ministry of education set the curriculum, most elementary schools taught only basic writing, reading, and calculation as they had in the Edo period because most teachers were unable to instruct in much more. In 1882 the ministry of education changed the initial educational system by dividing elementary schools into three levels: 3 years for the first stage, 3 years for the second stage, and 2 years for the last stage. Science was taught from the second stage onward. The first 4-year education became compulsory in 1887. The school attendance rate was about 50 % at that time and grew to more than 99 % by 1917. The majority of the population did not attend school beyond what was compulsory, however. Those who learned science, therefore, were of a relatively small number due to the position of the subject in the curriculum.

The number of middle schools grew only slowly. Curriculum guidelines for middle schools were published by the ministry of education in 1882. There were vocational-oriented middle schools and academic-oriented middle schools.

Governmental examination of school textbooks began in 1887 in order to determine compliance with national standards. This textbook examination system continues to the present.

68.2.2 The School of Engineering and the Imperial University of Tokyo

The establishment of a modern university was a main goal of late-nineteenth century educational reforms. Only one university, though, was launched by 1877 following the 1870 law governing university education. Its predecessor was the school of European culture the Edo government had established in 1855.

The basic idea behind the higher education was nationalistic. The first item of the Imperial University Law explicitly stated that Imperial Universities were for teaching and research in the arts and sciences to meet the country's needs (帝国大学令第一条　帝国大学ハ国家ノ須要ニ応スル学術技芸ヲ教授シ及其蘊奥ヲ攷究スルヲ以テ目的トス). It envisioned the Imperial Universities as contributing to national power and prestige through practical research and basic science. Consequently, certain dimensions of NOS were not emphasized, and Western notions of science and technology were still in the process of being integrated into the Japanese conceptual framework for science education.

The University of Tokyo began offering courses with four schools in 1877: the schools of law, literature, science, and medicine. The school of science had opened in 1876 with ten departments: mathematics, physics, chemistry (basic chemistry and applied chemistry), biology (zoology and plant biology), astronomy, engineering (mechanical engineering, civil engineering), and mining. Emphasis was placed on applied science and engineering at first.

With a ministry of industry opening in 1870, a school of engineering opened in 1873 before the University of Tokyo. The school of engineering began to offer classes in 1875. Yamao Yozo advocated national educational institutions of engineering.

An elementary school of industry was also proposed but unrealized. The ministry of industry planned to hire a chairperson and six lecturers from industrialized Scotland; in the end nine lecturers were hired. Henry Dyer, who learned mechanical engineering in Anderson College in Glasgow, came to Tokyo to work as the chairperson of the new school of industry in 1875 when he was 25.

Dyer crafted the school's mission: an institution with a comprehensive coverage of engineering. Thus, the school had seven departments from the beginning: civil engineering, mechanical engineering, architecture, electronics, chemistry, metal engineering, and mining. Each department offered both theoretical and practical aspects of its field. The school had a 4-year course of study, each with a modest tuition fee of ten Japanese Yen a year. Excellent students were sent to Europe after graduation.

The four departments of engineering and applied science at the University of Tokyo were separated from the school of science in 1885 to be merged with the school of engineering of the Imperial University of Tokyo and the school of engineering earlier established by the ministry of industry. Those lecturers from Scotland moved to the Imperial University of Tokyo. The school of science of the Imperial University of Tokyo had seven departments: mathematics, astronomy, physics, chemistry, zoology, plant biology, and geology. It also had a research institute of marine science and a school of agriculture. The schools of engineering and agriculture were intended to promote industry, while the school of science concentrated on basic science.

The Imperial University then invited more lecturers from European countries, while young Japanese elites were sent to European countries to study industrial systems and scientific and technical knowledge. Some of them taught in universities after coming back to Japan, but most went to the government to establish social systems. Initially students of engineering were sent to England, but later more students went to the United States. Medical students along with students in the humanities, social sciences, and physics were mainly sent to Germany.

More Imperial Universities were established after Tokyo: Kyoto, Tohoku, Kyushu, and Hokkaido. Furthermore, educational institutes for engineers were established. Tokyo Institute of Technology was established in 1881 as the Tokyo Vocational School. The name was changed to Tokyo Technical School (1890) and later Tokyo Higher Technical School (1901). In 1929, Tokyo Higher Technical School was elevated to a degree-conferring University as Tokyo Kogyo Daigaku (Tokyo Institute of Technology). The introduction of history and philosophy of science and technology as subjects of instruction had been discussed since 1930s at Tokyo Institute of Technology, whose institutional model was Massachusetts Institute of Technology.

Private schools attracted students who wished to learn modern science as well as foreign languages. Tokyo professional school, which is the precursor of Waseda University, was established in 1882 with four schools: political science and management, law, science, and English. The school of science disbanded after 3 years, but a new school of science and engineers was established in 1908.

Fujiwara University of Engineering was the first private university dedicated to science and engineering. It was established in 1939 by Ginjiro Fujiwara, the first president of Oji paper manufacturing company. He intended to donate the university to his alma mater, Keio University. It eventually merged with Keio University as a school of science and engineering in 1944.

Due to the increasing number of institutions of higher education, the number of engineers continued to grow. There were 1,500 graduates from colleges and their equivalents in 1900; 5,000 in 1910; and 55,000 in 1934. These technical graduates found employment in the government as well as in industry. The transfer for technology government to industry began around WWI.

Still, NOS and HPS remained the exception rather than the rule in Japanese higher education. Tohoku University had a position of philosophy of science in the school of science. It also planned to have a permanent position for Japanese mathematics (wasan), but budgetary limitations did not allow for it. Only a wasan archive was introduced in the university library. Tokyo Institute of Technology had HPS positions; the tradition continues to the present as a part of the department of management engineering. Those positions were considered as part of a liberal arts education for scientists and engineers, but they were always secondary to specialized fields of science and engineering.

68.2.3 Nature of Science in Japanese Literature of the Meiji Period

Although nature of science was not widely taught in Japanese education in the Meiji and Taisho periods, there were popular novels and essays which dealt with nature of science.[3] They influenced Japanese ideas of science.

Terada Torahiko (1878–1935) was a geophysicist, essay writer, and haiku poet. He taught physics in the Imperial University of Tokyo and had studied in Berlin. At the same time, he was a core member of the literary community with Natsume Soseki. He published a number of popular essays whose main topic was nature of science. Terada criticized lectures at all educational levels that crammed knowledge of science into them. “When teaching science,” he argued,

> teachers must be most careful to nurture children’s minds for research. That goal is not reached if they are merely given pieces of knowledge. Today even university students who are science majors are not motivated to do research by themselves. Their knowledge tends to be superficial. So it seems that they remember from their education in elementary schools to be content only with remembering knowledge (Terada 1918, p. xx).

---

[3] The importance of popular culture in public’s interest in science in Japan continues to the present. The atomic bomb case before and after WWII was discussed in detail in Ito (2010), for example.

Terada was close to Ishihara Jun (1881–1947), a physicist. Ishihara studied physics under Einstein at Zurich Institute of Technology in 1914 and taught in Tohoku University, where he resigned due to love affair in 1921. He then became a professional author of NOS topics to gain popularity from a wide range of audiences. When Einstein came to Japan in 1922, Ishihara served as an interpreter. He published many popular articles in which he emphasized the analysis of observations and experimentation in terms of quantification and measurement as an effective means of dealing with abstractions and new phenomena (Ishihara 1936).

68.2.4 Ashio Copper Mine Accident (1885–current)

The Ashio copper mine accident turned into a social movement that changed opinions about the value of Western science. The mine was discovered in 1550, and its operation began 1610. Its production decreased after the early seventeenth century, but the Edo government kept it open. After 1877 when its ownership moved to Furukawa Ichibei, its production grew drastically with modern technology. The amount of sulfur dioxide produced during the refinement process jumped up, and the surrounding environment was heavily polluted by 1890. Polluted water contaminated crops in widespread areas.

The pollution accident was the first civil movement against the government's role in producing pollution in Japan. Tanaka Shozo, a politician of the affected area, led residents to demand compensation from the government. They also wanted the government to stop mining in Ashio. The government kept the mine open, however, due to the first Sino-Japanese War (1894–1895), the Russo-Japanese War (1904–1905), and WWI (1914–1918).

68.2.5 Impacts of WWI to NOS in Japan

Technology was transferred from the governmental sector to industry during WWI in Japan. Scientist and engineers from universities were assigned to the industrial sector as production shifted for wartime needs. As the war escalated the government planned domestic centers for research and development. In 1917 RIKEN was established. It was the first comprehensive research institute of basic and applied science in Japan. While practical goals were emphasized due to the government's policy of industrialization, RIKEN also devoted considerable resources to basic science. It supported Japanese physicists in international research in quantum physics and particle physics especially between 1925 and 1950.

The physicist Nishina Yoshio (1890–1951) built the first cyclotron in Japan (the second in the world) at RIKEN in 1937 for nuclear physics and its application to radioisotopes in medicine and biology. Research in nuclear physics was connected to potential military applications of atomic energy: Japan's atomic bomb program in

WWII was located at RIKEN. The development of uranium mines in Japan began in 1938, but mining ended after the WWII. Nuclear development resumed for non-military purposes in 1954 as a result of the "Atoms for Peace" program. The first postwar uranium mine in Japan, the Ningyo Toge mine, opened in 1955. It produced uranium until 1987, but the amount was not enough for practical uses.

68.2.6 Kyoto School of Philosophy

The Kyoto school of philosophy,[4] represented by Nishida Kitaro (西田幾多郎) and Tanabe Hajime (田辺元), argued for the close relationship of science, technology, and philosophy. Under the influence of neo-Kantian philosophy,[5] this school developed the philosophical position that science and philosophy have connections to an epistemology based on Zen Buddhism and Husserl's phenomenology. Nishida's main work, *An Inquiry into the Good* (1911), includes an acknowledgement of the restricted nature of science as a form of knowing: "A scientist's way of explanation is slanted toward just one aspect of knowledge, whereas for a complete explanation of reality we must satisfy intellectual demands as well as the demands of feeling and the will" (Nishida 1911, p. 50).

The school of science at Tohoku University was one of the few that regularly offer courses in NOS/HPS, a practice it continued until the 1990s. Philosophers took the lead in the early period. The first lecturer of NOS was Tanabe Hajime. He began his career in the school of science at Tohoku University after graduating from the University of Tokyo. He taught NOS there and published *Saikin no Sizenkagaku* (*Recent National Science*) (1915) and *Kagaku Gairon* (*Outline of Science*) (1918). He also translated Poincare's *La Valeur de la Science* into Japanese (1916).

He moved to Kyoto and succeeded Nishida's position.[6] There he published *Suri tetsugaku kenkyu* (*A Study of Philosophy of Mathematics*). His held two views of the philosophy of science (Sawada 1997), but both were different from present notions. The first was a collection of scientific approaches to philosophy that included aesthetics and religious studies; the second was the idea that the philosophy of science was part of a philosophy whose subject was science. In the latter sense he wrote: "Science today . . . has reached the stage where scientific theory has gone beyond the position where its subjects are the entities and existents dealt with in science. Science is now in the position to realize things beyond philosophy. Science has become philosophy; philosophy is a subject to be described in a scientific theory.

---

[4] The development of HPS in Japan in its current sense is almost absent in the Kyoto School, as the school was accused of contribution to the Japanese navy after WWII.

[5] Manuscripts of Nishida and Tanabe can be examined online at the Kyoto school archive. http://www.kyoto-gakuha.info/

[6] Tanabe's position in Tohoku was taken by the philosophers Takahashi Satomi and Miyake Goichi, both of whom studied under Edmund Husserl.

In fact the new quantum theory of physics represents such a state of knowledge" (Tanabe 1963, p. 285).

Tanabe's illustrations of quantum mechanics as well as Ishihara Jun's commentaries on the theory of relativity, where their intended audiences were the general public, inspired young Yukawa Hideki, who later specialized in particle physics.

68.2.7 Science Education and NOS During WWII

Every aspect of Japanese society turned to the wartime efforts during WWII. Education was no exception. The purpose of mathematics and science in elementary schools was stated in a nationalist way: "to train the ability to think precisely and process normal events and phenomena and to apply this ability to everyday practice and to nurture rational and creative mind in order to prepare for contributions to the prosperity of the nation." (通常ノ事物現象ヲ正確ニ考察シ処理スル能ヲ得シメ之ヲ生活上ノ実践ニ導キ合理創造ノ精神ヲ涵養シ国運ノ発展ニ貢献スル素地ヲ培フコト[7])

The possibility of an exemption from military service motivated students to study the natural sciences, engineering, and medicine even in the later stages of the WWII when university students of social science and humanities were still being ordered to the front lines.

Paradoxically, though, the word "scientific" became a code word for left-wing movements and so was banned under the wartime militarism. Discussions concerning the social meaning of technology went underground during the war and stayed there for some time after the war.

At the same time, Sogensha, an Osaka-based publisher, published a series of classics of science. It includes a Japanese edited version of the Unity of Science (*Einheitswissenschaft*) work, but it was neglected.[8]

68.3 Higher Education in Japan After the WWII

68.3.1 Reform of Education After the WWII

Before and during WWII, the notion of science had been distorted to emphasize its nationalistic aspects. Every activity turned to wartime efforts.[9] Japan's surrender in 1945 led to a restructuring of the entirety of Japanese society and largely along

---

[7] Ministry of Education (1941).

[8] Sawada (1997), p. 3.

[9] Okazaki and Okuno-Fujiwara (1999) points out that the social systems of Japan during the WWII essentially continued after the war under different names.

American lines. The Japanese educational system, formerly shaped by the strong influence of the German educational system, was no exception. Reform was realized in the fundamental education act (1947), the school education law (1947), and the standards for establishment of universities (1956).

The reform was in fact an introduction of American educational system with some lead by CIE-GHQ. The Standards for the Establishment of Universities was announced 1949. The standard general education in universities as occurred in the United States—which required every student to take some courses in humanities, social sciences, natural science, language study, and physical education – was introduced to Japan. The main body of the instructors of general education, however, came from former high schools, while university professors had more power with governmental policy to enhance science and technology.

This idea of a standard general education included basic courses in the natural sciences, including for students of the humanities and social sciences. Specialists taught these natural science courses. In this context, NOS-like courses were welcomed by students in humanities and social science as courses requiring less background knowledge in the sciences.

Students studying science and technology jumped in national universities during the 1950s: the number of entering students in science and engineering increased from 142,546 in 1952 to 202,334 in 1957. Popularization of higher education in Japan occurred in the late 1960s, when baby-boomers approached college-entrance age. The number of first-year students in universities and colleges jumped up to 598,872 in 1975 from 273,098 in 1963.

While science and technology grew in national universities as a result of a concentration of investment by the ministry of education, private universities were established to meet the growing demands of higher education especially for majors of business and the social sciences. National and public universities focussed on engineering, natural science, and medical departments. Yet, each type of university – public and private – had comparable tuition and fees due to subsidies.

Many private universities did not include science and technology in their upper divisions, although they still had to offer natural science courses for students of the humanities and social sciences. They often hired historians of science for such courses on a budget smaller than that for researchers in science and engineering who required expensive laboratories and experimental equipment.

Research universities with schools of science and engineering did not put much emphasis on NOS. Scientists taught natural science courses for students of the humanities and social sciences in general education. They were not necessarily courses on NOS but basic introductory courses. Professors of the natural sciences in the upper division focussed on research more than education. The training of students in natural science and engineering emphasized research skills. This emphasis has not changed since the end of WWII.

University standards were revised in the Deregulation of University Act (taikoka) of 1992. The relaxation of regulations did not specify general education requirements, the student/faculty ratio, or the requirements for facilities. Most universities disbanded their general education divisions as a result of deregulation. Former general education teachers were moved to other departments or to a new faculty or stayed in general education. The number of universities electing retaining general education, however, was small. Hence, the number of teaching positions of general education has decreased because retired faculty members have not been replaced; the positions have moved to upper division. Faculty members appointed in the previous system (appointed in or before 1949) retired by 1992 due to age restrictions. Students are now not required to take any natural science courses, and NOS/HPS courses have been either taught by part-time lecturers or discontinued.

68.3.2 Yukawa on Science in Late-Twentieth Century in Japan

Science essays were popular even after WWII when the formal education system in Japan was under a total reform. Yukawa Hideki, a physicist and the first Nobel laureate of Japan (1949), committed himself to public awareness of science. His writings on NOS issues were influential.

For example, Yukawa (1945) asked:

> What should be done to promote science in Japan? There are two typical answers. One: practical research in short-term goals has been overemphasized in Japan; basic science should be stressed from now; for that, scientific mind must be nurtured; research and education of history of science, for example, will be effective. The other typical answer: science education has focused on theory without connection to the real world; knowledge of the facts are essential; students should act by themselves; they should first get accustomed to operate various machines although they may not fully understand principles. Those answers seem to be totally opposite. The direction of science education will be significantly affected which answer we think right.
>
> Then, what have we lacked? I would say, in short, we lacked "thought". This sort of consideration would arise various oppositions. Theoretical research and imagination will just have no relationship to sound development of science and no advantage on science. There actually are various thought in Japan. Native philosophy has grown in Japan. (Yukawa 1945, p. 10)

Yukawa was vocal in arguing against the military uses of atomic energy. He signed the Russell-Einstein manifesto in 1955 and attended the Pugwash conference in 1957. His thought on science and society resulted as the Yukawa-Tomonaga manifesto in 1979.

68.3.3 NOS/HPS Societies in Japan

Yukawa also set the stage for interdisciplinary discussion on NOS. He was one of the founders of the Japan Association for Philosophy of Science in 1954. The association publishes the Japanese journal *Kagaku Kisoron Kenkyu* (1954-) and the English journal *Annals of the Japan Association for Philosophy of Science* (1956-). The title of this association does not have the Japanese word for philosophy "tetsugaku";

its literal translation is “Association for the Foundational Studies for Science.” The reason of the name sometimes is said that some scientists did not like the word. Philosophers of science were unhappy. Uchii Soshichi explained:

> Thus, the Japan Association for Philosophy of Science started in 1954; but that was not the end of the matter. Many philosophers were frustrated. There were two groups, one with the name “American Philosophy Group,” the other with the name “Logic of Science Group;” and they decided to meet annually with the title “The Meeting for Philosophy of Science” beginning in 1957. And these meetings led, eventually, to founding another association, with the literal title of “Philosophy of Science” (in Japanese) in 1967; that is the Philosophy of Science Society Japan (PSSJ). Thus we now have two associations for philosophy of science, which is quite unusual in the world. And this reflects the relationship between philosophers and scientists in Japan. (Uchii 2002)

The Japanese Philosophy of Science Society partially overlaps with the Japan Association of Philosophy of Science in terms of memberships especially among philosophers. The latter covers analytic philosophy and philosophy in the English-speaking world in general.

Such a history led to the current situation of Japan, where HPS-related domestic academic societies currently are mixed. Most were established in the late-twentieth century and remain small to middle sized like other academic societies of humanities and social sciences in Japan. The History of Science Society Japan (1,000 members) was established in 1941 and publishes *Kagakushi Kenkyu*「科学史研究」 (Japanese) and its English journal *Japanese Studies in the History of Science* (1962), which was followed by *Historia Scientiarum* (1980-). It has offered seminars to the public since 1975.

Other national-level societies include the Japanese Society for Science and Technology Studies and the Japanese Society for the History of Chemistry. There are many other regional societies and societies of each area, such as industrial history.

68.3.4 Department of History and Philosophy of Science in the University of Tokyo

HPS was introduced to Japan as an interdisciplinary subject in the course of educational reform after the WWII by Professor Tamamushi Bun-Ichi, who visited the United States. At Harvard University in 1950, he found the strong influence of Alfred North Whitehead and George Sarton. The delegates including Tamamushi agreed that such an interdisciplinary field would be of strong social needs in restoration of the country.

Tamamushi launched the Department of History and Philosophy of Science at the University of Tokyo in 1951, as a part of trial to introduce general education in the upper undergraduate program. Another founding member was a biochemist-historian of science, Kimura Yuichi. Later the botanist-historian of science Kimura Yojiro and philosopher Omori Shozo joined. Omori was an assistant of Morton White at Princeton IAS in 1950s. Its graduate program was established in 1970.

Saegusa Hiroto (Yokohama City University) and Yajima Suketoshi (Tokyo University of Science) supported the inauguration of the department.

Nakayama Shigeru studied astronomy in the University of Tokyo and moved as a Fulbright scholar to the Department of History of Science at Harvard from 1955 to 1959. After obtaining his Ph.D. from Harvard, he went back to Japan to teach history of science at the University of Tokyo.

The HPS department in the University of Tokyo was the only institutionalized HPS department in Japan until 1993. The liberal arts section of Tokyo Institute of Technology also had philosophers and historians of science. Yoshida Natsuhiko, who translated Ayer's *Language, Truth, and Logic* into Japanese in 1955, was the main figure there to attract many students of a wide range of backgrounds from physics to management engineering.

There were other groups of philosophers of science in Japan, however.[10] For example, Ichii Saburo (1922–1989) was a philosopher of history with a physics background. He studied in University of Manchester and then studied under Karl Popper. He later adopted the British Marxist approach to history. After returning to Japan in 1954, he translated Bertrand Russell's work into Japanese. Another example is Sawada Nobushige (1916–2006), who taught philosophy of science in Keio University. He also studied at Harvard as a visiting scholar. He wrote a popular introduction to philosophy and did original research in epistemology and logic.

68.4 NOS/HPS in School Science (Rika) in Japan After the WWII

After World War II a national education standard was issued in 1947. Textbooks were authorized by Ministry of Education in accordance with the prescribed course of study. Teachers had to teach the recommended content. The course of study for elementary schools and junior high schools and the course of study for high schools have been revised eight and nine times, respectively.

68.4.1 NOS/HPS in the Early Postwar Period of School Science Education

After the war the 1947 national education standard, science was referred to as Rika. This nomenclature has not changed for the past half century. In the 1947 course of study, elementary schools and junior high schools were handled as a single unit. The initial stated purpose of science (Rika) was "to equip students with the following three qualities related to problems of the students' environments, so as to ensure that

---

[10] Sawada (1997).

all people can live a rational life and can enjoy better lifestyles": (1) the ability to look, think about, and deal with things scientifically, (2) knowledge related to the principles and applications of science, and (3) an attitude oriented toward finding and promoting the truth and creating new things. The following 13 sub-purposes were also identified (Ministry of Education 1947):

1. An attitude of being familiar with nature and an interest in scientific works
2. The ability to observe objects and phenomena in the natural world
3. The ability to think in a logical way
4. The ability to use machines and instruments
5. An interest in cultivating living things with care
6. Health-maintaining habits
7. Perseverance, willingness to help others, the habit of pursuing scientific work or research on one's own will
8. A desire to follow the truth and seek out the unknown
9. The ability to read easy science books
10. Knowledge of major scientific principles and their applications, allowing one to better understand the property of surrounding things and the relationships between them
11. Knowledge of the harmony, beauty, and bounty of nature
12. Respect for the work of scientists
13. Preparations for advanced science learning and necessary occupational preparations

Fujii (2005a) makes the following argument regarding the initial postwar purpose of science (Rika) education. The Japanese people had endured poor food, clothing, and housing conditions during the difficult years during and following World War II. Because it was a major social goal to somehow overcome these hardships and improve their living conditions, science education took on the characteristics of "Science (Rika) of everyday living." Nonetheless, it is interesting that the world "kagaku" is frequently used in the list of the purposes of Rika and that goals like cultivating "respect for the work of scientists" were included among its purposes.

The preliminary course of study for high schools, published in 1948, included separate proposals for physics, chemistry, biology, and earth science but contained no descriptions related to the science as a whole or anything related to the nature of science (Ministry of Education 1948).

In the 1951 revision, the junior high school and curriculum was coordinated with the high school curriculum, emphasizing the integrated nature of junior and senior high school education. Thus, the following were included among the purposes of science (Rika): science as a method and the use of scientific methods to solve problems, scientific attitudes and habits, the role of scientists and science in promoting human welfare and the development of contemporary civilization, and cultivating respect for specialists. These phrases applied to physics, chemistry, and biology (Ministry of Education 1951).

In the revised course of study for elementary school science prepared in 1952, science courses were expected to convey basic ideas on the nature of science, including the reality of natural phenomena and the objectivity and universality of science. Simple examples, such as the life cycle of the tadpole, were recommended as exercises suited to convey these notions. Beyond recommending the content of courses, revisions to the curriculum also specified the need for elementary children to understand the argumentative qualities of scientific knowledge, which the reforms viewed as linked to the students' engagement in simple investigations, in making predictions, in conducting experiments, and in comparing results. In this way students came to understand, the reformers believed, not only the persuasive qualities of scientific knowledge but also how new knowledge was created and competing results reconciled (Ministry of Education 1952).

68.4.2 NOS/HPS in School Science During the High-Growth Period

Japan became an independent nation in 1952 and in 1957 became a new member of the international community by joining the United Nations. This move was accompanied by developments in science and technology, including the enactment of the Vocational Education Promotion Act in 1951 and the Science Education Promotion Act in 1953. Revisions made to the course of study for elementary schools and junior high schools in 1958 and for high schools in 1955 (Ministry of Education 1955) represented an important turning point that shifted the focus of science education in Japan toward the natural sciences.

The stated purpose of elementary school science (1958) included the term "natural scientific" rather than just "scientific," and in high schools (Ministry of Education 1955), two of the four science subjects (Physics, Chemistry, Biology, and Earth Science) were made mandatory (further revisions in 1960 made four of the following courses mandatory: Physics A and B, Chemistry A and B, Biology, Earth Science). With these revisions, which can be viewed as a shift toward natural science fundamentalism, the content related to NOS was eliminated from the purposes and content of the course of study. What remained were descriptions of the "methods of natural science." It was in this revision that the term "scientific inquiry (*tankyu*)" first appeared within the stated purposes of Science (Rika) in the course of study for junior high schools and high schools.

In the revisions made to the course of study for elementary schools in 1968 (Ministry of Education 1968), for junior high schools in 1969 (Ministry of Education 1969), and for high schools in 1970 (Ministry of Education 1970), which occurred in the middle of the high-growth period, systematic learning that conformed to the systems of natural science was steadily promoted, and the emphasis was placed on understanding scientific methodology and the process of scientific inquiry. Given that the four subjects listed above were mandatory in high school science programs, a "Basic Science (Kiso Rika)" introductory course was established to ease the burden of taking the more specialized courses later on. One of the stated goals of this course was "to teach the methods of science" and "to make students aware of the contributions that natural science has made to improving human welfare" (Ministry of Education 1970).

68.4.3 NOS/HPS in School Science Education During the Stable Growth Period

As both the positive and negative aspects of the high-growth period began to be revealed, Japanese society found itself facing a variety of social problems that directly affected education. In a period of material affluence and prosperity, the issue of the pressures placed on students and student overwork – both the result of strict national standards – surfaced. At the same, Japan's low birth rate emerged as a central social issue. The keyword in the revised course of study around this time consequently was "yutori" (relaxed/pressure-free).

In the 1977 revisions to the course of study for elementary schools and junior high schools, the purpose of science (Rika) was condensed into a highly simplified form and the total class hours devoted to science reduced. For example, the purpose of elementary school science was "To cultivate the skills and attitudes needed for exploring nature through observation and experimentation, to facilitate understanding of natural events and phenomena, and to cultivate a deep sense of appreciation for nature" (Ministry of Education 1977a). In junior high school, students in all grade levels had been required to take 4 h a week in science classes up to this point, but the requirement was changed to 3 h per week for first- and second-year students. It is important to note that at this time, the word "science (*kagaku*)" was eliminated from the stated purposes of school science (Rika) in the course of study for elementary schools and junior high schools (Ministry of Education 1977a, b).

In the course of study for high schools published in 1978, science courses were completely reorganized and a standard number of credits were established (Ministry of Education 1978). These were as follows: Science (Rika) I (4 units), Science (Rika) II (2 units), Physics (4 units), Chemistry (4 units), Biology (4 units), and Earth Science (4 units). Science I – which was established to cover the content students had to learn prior to junior high school and to prepare them for further advanced learning – became mandatory, but no NOS content was included in the subject.

On the other hand, the stated purpose of Science (Rika) II, which was newly established by this revision, was "to identify issues related to events and phenomena that can be seen in the natural world and related to historical examples of science; and through scientific inquiry, to teach the methods of science and to cultivate problem-solving skills." In this revision the history of science entered into the science curriculum through the examination of historical examples of important scientific discoveries that demonstrated how principles and theories were established. Because Physics, Chemistry, Biology, and Earth Science, as well as Science (Rika) II had been made elective courses, the number of students electing Science (Rika) II was not so high compared to the number of students electing other courses.

In revisions made to the course of study for elementary schools (Ministry of Education 1989a) and junior high schools (Ministry of Education 1989b) in 1989, when the Showa era gave way to the Heisei era and educational reform for the twenty-first century was just beginning, the stated purpose of science (Rika) included terms like "the cultivation of scientific ways of looking and thinking" and "science (*kagaku*)," but statements related to NOS were still absent. In junior high school science (Ministry of Education 1989b), an elective science course, offered once a week, was established, and efforts were made to allow students with a particular interest in or passion for science to engage selectively in scientific inquiry.

Following the trend among elementary and junior high schools, major changes were made to the 1989 course of study for high schools with regard to science (Rika). The basic policy was to "establish course diversity." This change occurred in an environment where there was little freedom of selection in science courses, and courses were not able to accommodate sufficiently differences in students' skills, aptitudes, and preferred plan of study (Fujii 2005b). Thus, 13 elective courses were established: General Science (Rika) (4 units), Physics IA, Chemistry IA, Biology IA, and Earth Science IA (2 units each), Physics IB, Chemistry IB, Biology IB, and Earth Science IB (4 units each), Physics II, Chemistry II, Biology II, and Earth Science II (2 units each) (Ministry of Education 1989c).

Content related to NOS/HPS was still covered in the General Science class, but it only appeared as the "Study of cases of experiments in scientific history," which was one of three items in a list of "Research Topics." Considering the scope and level of the content, it was noted that "regarding important discoveries in the history of science, students should learn about the process by which principals and theories are established through the repetition of experiments and review of the scientific literature." Miyashita (2006) proposed using an earth science textbook with emphasis of history on geology and NOS for high school students and first-year college students. His idea was that the history of plate tectonics – a twentieth-century discovery – gave students a good grasp of how geological ideas had developed and, by implication, how science operated. The textbook also covered topics of national importance, including astronomy during the Edo period and the development of seismology as a native Japanese science.

68.4.4 NOS/HPS in School Science Education in the New Century

The key phrase found in the revised course of study of 1998 (elementary and junior high school) and 1999 (high school), at the dawn of the new century, was "a zest for life (*ikiru-chikara*)." Schools were asked to cultivate in students a rich sense of humanity and the ability to learn and think on their own. While descriptions of the purpose of science at the elementary school and junior high school levels included the usual wording concerning "carrying out observations and experiments," it was emphasized that students would do so "with their own prospectuses" (Ministry of Education 1998a) or "with a sense of purpose" (Ministry of Education 1998b). While this wording emphasized active problem-solving by students, other sections also reflected a departure from the simple empiricism-oriented teaching methods through which scientifically appropriate knowledge was cultivated through verification and falsification (Kadoya 1998).

Subjects were again reorganized in the 1999 revisions to the course of study for high schools (Ministry of Education 1999). With regard to NOS/HPS, a Basic Science (Rika Kiso) class (2 units) was newly established, with the stated purpose mentioning "the relationship between science and human activity" and "the scientific inquiry and investigation of nature and the process of scientific development." In terms of content, the guidelines included references to the "beginning of science" and "scientific inquiry into nature and the development of science." They addressed the inquiry into the origin of matter, which ultimately led to the development of science, cell discovery and theories of evolution, the process of establishing ways of thinking about energy, and the Copernican theory and plate tectonics. Students were required to select two of the following courses: Basic Science (Rika Kiso), General Science (Rika Sogo) A and B (2 units each), Physics I, Chemistry, Biology I, and Earth Science I (3 units each). To enable students to gain a broader range of basic science skills, they were also allowed to include one or more of the following courses in their curriculum: Basic Science, General Science A, or General Science B. Basic Science was no longer included as an entrance examination subject.

At the same time the Science and Technology Basic Law was enacted in 1995. It called for Japan to be "a nation based on the creativity of science and technology." The justification for this legislation cited three expectations of science and technology (S&T) for the twenty-first century. Science and technology were expected to lead to creative, cutting-edge developments and the creation of new technologies; contribute to solutions to the various problems that humanity will face in the future, including environmental problems, food, and energy problems, and AIDS; and create new cultures related to human life, society, and nature. The Science and Technology Basic Law also contained references to science education. Chapter 5, Article 19 stated that "the nation should implement necessary policy measures to promote the learning of S&T in school and social education, to raise awareness of S&T and to disseminate knowledge of S&T, so that all Japanese people, including the young, have every opportunity to deepen their understanding of and interest in S&T."

The Fourth Science and Technology Basic Plan,[11] approved by the Cabinet in 2011 based on this law, called for Japan "to consistently and systematically nurture talented children to lead the next generation" and "to enhance the interest of children in science and mathematics starting in elementary and secondary education so as to increase the population of children interested in such subjects, and to identify talented children and develop their abilities." The Super Science High School Project undertook various efforts to cultivate student interest in science and technology based on plans created by each school, such as developing classes based on an independent curriculum, forming partnerships with universities and research institutions, and conducting research on issues that take advantage of local conditions. Launched in 2002, the budget for this project grew to more than three times its original size, and it is still growing.

---

[11] Also see Sect. 68.5 of this chapter.

The 2008 version of the course of study for elementary schools and junior high schools continued to highlight the key phrase “a zest for life (*ikiru-chikara*)” but incorporated major reforms. Specifically, the number of classroom hours devoted to elementary school science was increased from 350 to 405 (MEXT 2008a). The number of classroom hours devoted to junior high school science was increased from 290 to 385 (MEXT 2008b). These changes were expected not only to increase the quantity of science content but to improve qualitatively the process of scientific inquiry through the introduction of observational experiments and report writing by students. Emphasis was once again placed on the connection between science and everyday life. In the 2009 version of the course of study for high schools (MEXT 2009), “Science (Kagaku) and Our Daily Life” was established as the subject equivalent to the former “Basic Science (Rika Kiso),” and course names that included the word “General” were eliminated. The curriculum now consisted of Basic Physics, Basic Chemistry, Basic Biology, and Basic Earth Science (2 units each), and Physics, Chemistry, Biology, and Earth Science (4 units each) (MEXT 2009).

The purpose of the Science (Kagaku) and Our Daily Life subject was “to understand scientific view and methods and to inspire interests in science via experiences of observation and experiments of phenomena in everyday life in a fashion fit for the needs of vocational high school students.” History and philosophy of science were thereby eliminated from the official school curriculum of Japan, and science had only weak connections to other subjects. The course content was divided into three major segments: the development of science and technology, science in everyday life, and science and everyday living in the future. Students could either (1) take two of the following subjects, as long as one of them is Science and Our Daily Life: Science and Our Daily Life, Basic Physics, Basic Chemistry, Basic Biology, and Basic Earth Science or (2) take three of the following classes: Basic Physics, Basic Chemistry, Basic Biology, and Basic Earth Science.

University entrance examinations have excluded NOS/HPS-related content in favor of focusing on specialized subjects. The National Center for University Entrance Examination again announced in April 2011 that its examinations would not include “Science (Kagaku) and Daily Life” because that topic now appeared too general for high school instruction. As a result, high schools evaluated by the number of students accepted to prestigious universities would probably elect to eliminate NOS/HPS in order to spend more time on subjects considered to fit to entrance examinations.

This revision moved Japanese science education away from what was intended in the immediate postwar period, which at the elementary school level addressed the basic idea of science and at the high school level had taken up the systematic nature of natural science. Given that contemporary society is grounded in science and technology and the world has become a place where scientific knowledge is becoming increasingly globalized and technologies developed through continuous innovation, it is important for all people, regardless of gender or age, to have a wide range of knowledge of science and technology, as well as flexible ways of thinking and making decisions. This development may be called neo-scientism in the school science of the twenty-first century.

68.5 The Science and Technology Basic Plans and Their Impacts on NOS

The Science and Technology Basic Law (1995) led the Japanese government to issue four Science and Technology Basic Plans (1996–2000, 2001–2005, 2006–2010, and 2011–2015), which aimed to enhance the roles of science and technology in Japanese society. Each included NOS components, with foci on public awareness of science and enforcement of school science.

68.5.1 The First Science and Technology Basic Plan

The first Science and Technology Basic Plan, issued in 1999, lamented the public's low esteem of science and technology. So the first plan was designed to "gain the public's deep and broad understanding for the promotion of science and technology with full respect towards harmony with humans, society, and nature" by implementing government measures to improve public understanding of science and technology, a task for which they expected the cooperation of specialists in the production of "easy-to-understand information on science and technology" (pp. 14–15).

The first basic plan targeted the improvement of science and technology education in school education by focusing on teaching methods and new facilities, such as computer-aided learning facilities, as well as by emphasizing the practical aspects of science and technology (p. 42). A National Museum of Emerging Science and Innovation (*Kagaku Miraikan*) was established in 2001 in the framework of this basic plan for science and technology as the center for promoting science and technology. NOS/HPS content did not appear in the first basic plan, though.

Independently of the basic plan, the Japan Accreditation Board for Engineering Education was established in 1999 for accrediting engineering programs complying with international standards of engineering certification. As the international standard for engineering education includes an ethics requirement, universities which intended to offer JABEE-accredited programs were forced to introduce engineering ethics courses. The impact on NOS/HPS was limited, however. Most "ethics" courses were dedicated to practical aspects of engineering, such as compliance with regulations or general workplace ethics as a part of the social accountability and responsibility of engineers. Only a few programs invited NOS/HPS researchers to include other dimensions of science and technology in the curriculum.

The Japanese Society for Science and Technology Studies was established in 2001. Kobayashi Tadashi, the first president of the society, remarked in the prospectus of the society that twenty-first century technoscience entailed sociopolitical and philosophical challenges. He pointed out that the

> uncontrolled production of artificial goods is fast overwhelming the natural world, aggravating an already precarious environmental crisis; developments in biotechnology and information technology threaten the survival of traditional lifestyles and value systems. Human societies and individuals need to rethink their relationship with technoscience. (Kobayashi 2006)

68.5.2 The Second Science and Technology Basic Plan

The Second Basic Plan (2001) cited the importance of communication between science and society, but its main focus was mainly on communication between researchers in science and engineering and those in the social sciences and humanities. The public's understanding, assessment, and acceptance of science were mentioned, but the major actors charged with evaluating science and technology were natural scientists, technological experts, and experts in the social sciences and humanities. This second plan cast the reform of science education in the context of international competition, a long-standing motivation for training scientific specialists.

The role of the public in the advancement of science and technology was specified in the fifth chapter of this plan as embracing a responsibility to understand the role of science and technology in daily life, a recognition that science and technology are synergistic activities, and an obligation to develop a level of scientific understanding enabling one to make rational and independent judgments. Interestingly the plan believed that the development of this kind of scientific understanding could occur outside the educational area in institutions like museums.

Yet in spite of the attention paid to public understanding of science, the plan overwhelmingly emphasized the responsibilities of scientists and engineers to act in accordance with ethical standards. Hence bioethics, research accountability, and risk management among scientists and engineers were stressed to a greater degree than the public's responsibility to make rational assessments about science and technology.

68.5.3 The Third Science and Technology Basic Plan

The attitude toward NOS changed drastically in the third basic plan for science and technology (2004). An entire chapter was dedicated to science communication, especially through the proactive participation of the public in scientific and technological issues and the active engagement of scientists and engineers in communicating their work through outreach activities.

The emphasis on science communication in the third basic plan was a reaction to the discussion of issues related to bovine spongiform encephalopathy (BSE) in Japan. Although the Japanese government had discussions on BSE in the United Kingdom since the 1980s, it failed to respond adequately to the threat of the disease. Not until March 2001 did the government act, and by the end of the summer, a BSE-infected cow was found in Japan. An independent investigation in 2002 found the government lax in disseminating information on BSE and preparing the public for the possibility that the disease might be found in Japan. Ill-prepared and confused statements by the government generated public distrust as had also occurred in the UK. As a result the government tried to enact good practices of science communication.

Implementation of the third basic plan for science and technology began in 2005, which Kobayashi (2006) called the first year of science communication in Japan. The following steps were taken to improve the situation:

1. Three universities (Hokkaido University, the University of Tokyo, and Waseda University) introduced science communicator training programs with governmental support.
2. Osaka University launched the Communication Design Center, an interdisciplinary-oriented institute with a strong focus on research, development, and personnel training in science communication.
3. The National Museum of Emerging Science and Innovation began offering a training course for science communicators. It also hired science communicators with a fixed term.
4. The National Science Museum conducted a research project (2005–2008) on training and evaluation of science communicators.
5. Science cafes became common in Japan.

Nevertheless, it turned out that the activities and efforts of science communication had a limited effect in the Japanese society as the whole, with catastrophic results.

68.5.4 The East Japan Earthquake and the Fourth Science and Technology Basic Plan

One of the strongest earthquakes in human history hit eastern Japan at 14:46 on March 11, 2011. The epicenter was 130 km from the Miyagi prefecture coast. The earthquake's magnitude was 9.0, the fourth strongest of recorded earthquakes. It was the first gigantic earthquake where the earthquake waves were almost captured by recorders and subsequent events were broadcast to the world. Within 30 min at the earliest after the earthquake, a tsunami up to 40 m high hit Japan's Pacific coastal areas from Hokkaido to Chiba. About 20,000 people were killed in the tsunami and the earthquake; 118,621 buildings were razed; and 802,814 buildings suffered partial damage. Thousands of people lost their homes and livelihood as a result of the earthquake and tsunami.

The tsunami-affected area included the site of the Fukushima 1 nuclear power plant. Due to loss of electricity, the power plant lost control and four of its six nuclear generators exploded. Radioactive particles dispersed in the air and the Pacific Ocean. Over 113,000 residents in the Fukushima Prefecture evacuated due to high levels of radiation (Cabinet Office 2011). Broadcast in real time over television and the Internet, the earthquake, tsunami, and nuclear accident shocked the world.

The consequences of the Fukushima accident reverberated in the years that followed, and assessments of the damage to society, politics, and the economy were difficult. From an NOS/HPS perspective, the main issue concerned public trust, especially trust in experts. Initially professional opinions on the dangers from Fukushima varied. Some claimed, for instance, that the radioactive level would not immediately affect human body, while others insisted that everybody should evacuate eastern Japan immediately. Due to these contradictions and others like them, the public came to distrust the government, scientists and engineers, and even mass media (and some say, social media too). The public classified some researchers and other professionals as *goyo gakusha* (governmental junk scientists), while it identified others as “sound” professionals. But the public’s criteria for placing someone in one category or another were not clear, indicating a profound inability to assess independently “official” statements about the nature and extent of the crisis. Scientific communication had malfunctioned despite the science communication programs that had been inaugurated in the decade before the accident. Improving public understanding of science and the expert’s ability to communicate science were high priorities in the years following Fukushima.

A complicating factor was the unusual nature of the accident – the probability of a nuclear disaster following an earthquake was thought to be very low – making the crisis one of determining an “unknown unknown.” The environmental and health effects of low levels of radiation were not known, yet decisions had to be made in order to take action on the relocation of the population after the quake. For instance, before beginning the reconstruction of the area, wrecked homes and ships had to be examined for the level of radiation contamination, but it was not clear at what level the radiation was harmful. Reconstruction itself was difficult because debris from the tsunami was left on the roadside more than a year after the earthquake, and roads themselves were often so damaged that they became barriers to the heavy construction vehicles needed to clean up the sites. Finally, the sheer amount of debris exceeded the capacity of plants in the area. Thus, the restoration process needed informed expert *and* public decision-making at the national level.

Furthermore irrational nuclear fears surfaced. Some residents outside the Tohoku area reacted against Tohoku debris, believing that anything in Tohoku was contaminated by radioactive particles. While professional measuring of radiation levels was extensive, the public simply did not believe the data any longer due to the distrust of professionals formed in consequence of miscommunication after the earthquake, the tsunami, and the nuclear reactor accident at Fukushima.

The Fukushima disaster had an added dimension: how to manage the consequences of the tsunami and how to handle reconstruction so that the impact of a future tsunami could be minimized. Thousands of residents lost their homes and had to live in temporary housing. Residents wanted to return to their homes, but whether or not their homes were safe was difficult to determine. Hilly areas are naturally relatively tsunami-proof and it would have been appropriate to move the displaced population to them, but these areas were already built up with little room for expansion. Municipal governments often owned other available plots of land, but they were designated as parks or historical landmarks and therefore could not be occupied by survivors. An added complication was the loss of gainful employment in the area after the tsunami.

Discussions on those issues might have been a little easier if the Japanese public were well educated on NOS and if the public as well as the experts acknowledged that science cannot solve all problems by itself. Tadashi Kobayashi strongly argued for the importance of NOS education for the public in a cabinet meeting in April 2011 in the hope of changing the situation.

The fourth Basic Plan of Science and Technology (2011) was crafted with the problems caused by the earthquake in mind. Greater stress was placed on the role of science communication in social decision-making as well as in the public understanding and awareness of science than had been the case in previous basic plans. The fourth plan explicitly stated that the evaluation of scientists and their work now had to include consideration of the scientist's outreach to the public, including the communication of research results to society.

68.6 Conclusion

The promotion of science and technology in Japan after the Meiji restoration has been motivated by external pressures and global competitions. Engineering was favored over science in education in order to increase innovation through practical results.

NOS in school science (Rika) was the most clearly articulated in the course of study for elementary science revised in 1952 in the early postwar period. The word "science (kagaku)" disappeared from the course of study for elementary science revised in 1977. Shindo (1995) noted that "science," "scientific method," and "scientific inquiry" in Japanese science education should be reconsidered from the point of view of modern science studies. NOS has hardly appeared in any stage of education since it was not included on university entrance examinations, and, with few exceptions, it has been largely excluded from higher education programs in science.

In Japan university courses for science teacher training, even for science majors, usually do not have NOS/HPS-related content. So NOS/HPS is not required to be a science teacher. Toda (1992) investigated the views of science and science teaching methods held by science teachers in training and concluded that teachers in training were never fully conscious of their own specific views regarding science. They tended to hold traditional views of science as common sense, and their choice of science teaching methods was based on "familiarity" and "orthodoxy" rather than informed and up-to-date views of science.

International developments may compel Japanese science teachers to take a different view of their subject and their profession. In 1999 a declaration on science and the use of scientific knowledge was issued under the aegis of the United Nations Educational, Scientific and Cultural Organization (UNESCO), and the International Council for Science (ICSU). The declaration, which addresses scientific knowledge and science education, stated that "Science curricula should include science ethics, as well as training in the history and philosophy of science and its cultural impact" (The World Conference on Science 1999).

In Japan HPS grew in response to nationalist movements and educational reform after WWII. HPS courses since then have been offered mainly for non-science students, with the number of universities offering HPS courses decreasing after successive reforms in higher education. Crisis events such as BSE resulted in an emphasis on improving science communication rather than enhancing instruction in HPS. The earthquake of March 2011 and the subsequent nuclear accidents have drawn attention to NOS/HPS in Japan, but the integration of NOS/HPS courses into the Japanese educational system has been uneven, with most educational sectors ignoring NOS/HPS.

Thus, Japanese society began to realize the importance of NOS in the wake of the East Japan Earthquake and the nuclear accident that followed. There is still a long way to go to change Japanese attitudes in the direction of a deeper understanding of nature and of ways of studying and managing it. NOS and HPS can be of assistance in changing attitudes, but there is much to be done. Concerned parties need to be persistent.

Yuko Murakami is an associate professor, Graduate School of Science, Tohoku University. Ph.D (Philosophy, Indiana University), M.S. (HPS, University of Tokyo), and B.A. (HPS, University of Tokyo). Her research areas cover logic, analytic philosophy, philosophy of science, science, technology and society, and higher education. She is a member of the boards of the Japan Association for Philosophy of Science and the Japan Association of Contemporary and Applied Philosophy and of the editorial board of Philosophy of Science Society Japan.

Manabu Sumida is an associate professor of science education in the Faculty of Education, Ehime University, Japan. He holds a BS in chemistry from Kyusyu University and a Ph.D in science education from Hiroshima University. His research interests are focused on relating the cognitive and philosophical approach to science education and the cultural effects on science education. He is the author of "The public understanding of pendulum motion: From 5 to 88 years old" (In M. R. Matthews et al. (eds.) *The pendulum*, pp. 465–484, 2005) and "The Japanese and Western views of nature: Beyond cultural incommensurability" (In T. Papatheodorou (ed.) *Debates on early childhood policies and practices*, pp. 123–135, 2012). He is also the co-translator of "Science for All Americans" into Japanese. He was a committee member of the TIMSS 2003 study, TIMSS 1999 Video Study, and OECD PISA 2006. He received the Young Scholars' Award from the Japan Society for Science Education in 1996 and from the Society of Japan Science Teaching in 1999 and the Best Paper Presentation Award in 2007 and 2008 from the Japan Society for Science Education. He is currently Director of the Japan Society for Science Education, Executive Board of East-Asian Association for Science Education, and Country Delegate of the Asia-Pacific Federation of the World Council for Gifted and Talented Children.

Chapter 69
The History and Philosophy of Science and Their Relationship to the Teaching of Sciences in Mexico

Ana Barahona, José Antonio Chamizo, Andoni Garritz, and Josip Slisko

69.1 Introduction

Why is science so important in today's societies? Science (along with technology) is one of the salient endeavours of the contemporary world and, more than any other human activity, distinguishes the current period from previous centuries. According to Stehr, it is a widely shared assumption among contemporary social scientists that the immense impact of science and technology on society has become one of its defining characteristics (Stehr 1994).

Nowadays, we are experiencing the fourth, postindustrial, technoscientific revolution, where science and technology play an increasingly important role in most spheres of life and where our dependence on knowledge-based occupations is considerably growing (Böhme 1988). Contemporary society may be described as a knowledge society, based on the penetration of all its spheres by scientific and technological knowledge (Stehr 1994).[1]

---

[1] Some authors consider the first of the technoscientific revolutions to be the agricultural revolution; the second, the industrial revolution, (these two revolutions emerged from applying new sources of energy to mass production of goods and the transfer of information theory to industrial processes); the third the informatics and robotics revolution; and the fourth the postindustrial revolution. These revolutions were manifestations of the ever-increasing capacity of human beings to

Advances in science and technology deeply influence natural and social processes. Science and technology as an instrument of mediation between nature and society have transformed people's lifestyles and their relationship with the cultural and natural environment.

Now we know more about the way the world and the universe work; in matters of health many diseases have been eradicated, and many therapies have been found for others. On the technological side, modern agriculture and industry have been developed to cover the needs of more and more inhabitants of the planet, as well as increasing the possibilities to access information in real time with worldwide coverage. Modern societies cannot function without the products of science and technology; they are now so commonplace that they have become largely invisible.

Changes due to science and technology have generated transformations in the way knowledge is organized and have transformed societies into knowledge societies, where information is manifold, decentralized and available to more and more people around the world. This is why it has become essential to modify the current education system regarding science and technology in countries like Mexico. In order to do so, the inclusion of reflections produced by historical and philosophical studies has been a cornerstone over the last three decades.

The first part of this chapter is about the relationship between the history and philosophy of science and the teaching of science. It will allow us to emphasize the value that recent studies on the history and philosophy of science have had in science education in Mexico. On one hand, in it we stress the importance of the history and philosophy of a discipline in the teaching of science, and on the other, we insist in the role of science in modern societies and encourage science teaching within a historical and philosophical perspective. In the second part we will review the latest Mexican educational reforms in 1993 and 2006 and acknowledge the advances regarding the teaching of biology, physics and chemistry in basic education (elementary and junior high school) as well as the inclusion of the history and philosophy of science.[2]

69.2 The History and Philosophy of Science and Their Relationship to the Teaching of Science

Science, like other human activities, is a complex and social one (Longino 1990). We can say that science is a way of knowing about and explaining the world around us. It differs from other forms of knowledge in its particular ways of observing, thinking, experimenting and testing, which constitute the fundamental aspects of its nature. From a scientific perspective, things and events in the universe

---

control and manipulate their environment and resulted in important social and political changes (Hirschhorn 1986; Stehr 1994).

[2] A more broad approach had been boarded by two of the authors (Chamizo and Garritz 2008).

present consistent patterns which can be understood by means of systematic study. Scientists attempt to make sense of the observation of phenomena by formulating explanations based on scientific principles accepted by the community that are compatible with these phenomena.

Science can be understood as a process of knowledge production that not only has instruments which expand the senses and allow careful observations and interventions in phenomena but also establishes the theories which make sense of them (see, e.g. Golinski 1998; Hacking 1983).

Science has a history of elucidating many processes; the way human beings have observed and explained nature has changed through history. At the beginning of the nineteenth century, for example, the existence of genes was unknown, though it was known what happened when one crossed certain plant varieties. Nowadays we have the sequence of the human genome. Change in knowledge is evident and inevitable. Scientists reject the idea that one goal of science is to reach the absolute truth and agree that there is some uncertainty that is part of its nature and modification of knowledge is one of its norms; however, it can be said that most of scientific knowledge is long-lasting. What we know now can be modified or rejected by future observations or theoretical proposals. Therefore, stability and change are integral parts of the nature of science.[3]

Science is not only a collection of data. Concepts, scientific theories and methodologies, along with goals, values, aptitudes and abilities (which are handed down from generation to generation), are an integral part of science. When one teaches or learns science, one does not only teach or learn ‘scientific knowledge’ but also goals and values (objectivity, honesty, collaboration, conservation of nature), abilities (to observe, manipulate, calculate, measure, estimate) and aptitudes (curiosity, openness to new ideas, confrontation of different positions before problems, informed scepticism, communication). Scientific education can and must contribute towards enhancing people’s knowledge as well as to develop scientific values and/or social values in general positive aptitudes and abilities that help improve quality of life. In this sense, schools have an unavoidable social duty, as they are in charge of distributing scientific knowledge to the population.[4]

What is the importance of teaching science? Human beings have everyday principles, which allow them to interact with the world. However, science enables us to have a better quality interaction. In modern societies, active participation and a

---

[3] Thanks to recent studies on the history and philosophy of science, it can be said that the different ways in which humanity has explained phenomena, i.e. the different patterns of scientific explanation, have been modified over time (see, e.g. Martínez 1993).

[4] Values have been basic elements of the twentieth-century educational perspective in Mexico, for they have social, political and pedagogical content that expresses the standards of comprehensive human education. For this reason, values have been considered an asset whose conveyance and quality must be promoted. Their presence in the social milieu has been linked to the development of the Mexican educational system since the end of the nineteenth century (Latapí 2003). Nevertheless, as Wuest Silva and collaborators (1997) mention, the study of the role played by the values associated with science and pedagogy did not begin until the 1980s.

sense of critique[5] are essential before the magnitude of the problems we face. For example, in nuclear power, climate change, the loss of biodiversity, atmospheric pollution, serious diseases such as AIDS or cancer, to name a few, scientific knowledge has become valuable in itself, and these issues have caught our attention regarding the relationship between science and society (Shortland and Warwick 1989). The teaching of science and the acquisition of scientific knowledge have value because knowing science allows us to have explanations about natural or social phenomena and develop the capacity to solve problems with efficiency (Matthews 1994/2014).

Over the last three decades, the importance of the history of science in scientific education has been gaining recognition. Below are a few of the most important reasons. The study of the history of science:

- Helps us understand the nature of science as a complex cultural enterprise that can be presented as part of a wider cultural heritage (Jenkins 1989) and therefore helps place professional education appropriately within a broader cultural context. It is not about forming scientists at an early age (which may be a positive effect), but to form informed citizens with the capacity to decide, observe and manipulate their surroundings.
- Gives us a better understanding of the methods and concepts associated with goals and values which are characteristic of different times and that remain stable for long periods.
- Can enable future scientists to improve their response to the challenges posed by the rapid globalization of science and technology (Wilson and Barsky 1998); according to Gooday and collaborators (2008), the history of science has particularly important forms of knowledge and understanding concerning science that cannot be obtained so effectively by any other means, like the ability to read and interpret primary sources and formulate and defend a cogent argument (see also Solomon 1989).
- Allows us to understand how scientific goals and values go beyond disciplinary boundaries and contribute to the reorganization of disciplines and the development of technological advancement, important to the understanding of modern science. For example, the Human Genome Project would have been impossible without the participation of the most important technological firms in charge of making the sequencers, the big philanthropic foundations in charge of financing, the universities and higher learning centres where scientific knowledge is produced and disseminated, etc.
- Allows us to find suppositions which are shared by students and whose critique and abandonment are associated with important scientific advancements. The teaching of the history of science will allow students to locate these presuppositions (or previous ideas) and be in a position to abandon them rationally. For example, a serious

---

[5] The role of critical discourse in science is not a peripheral feature, but rather it is at the core of its practice, and without it, it would be impossible to construct reliable knowledge; for authors like Osborne (2010), scientific education must include critical discourse in the teaching of science to foster the ability to reason and argue scientifically.

problem in students at a higher learning level is their lack of post-Lamarckian evolutionary thought. Many explanations of evolutionary processes in these students are those that correspond to Lamarckism which explained, in the nineteenth century, that species were modified due to the needs imposed by the environment: the necks of giraffes were very long because these animals had to continuously stretch them in order to reach the foliage of trees, wisdom teeth do not come out because we do not use them, etc. This kind of Lamarckian thought, where the need creates the organ, is an idea no longer shared by scientists after the theory of evolution by natural selection that Charles Darwin proposed in 1859 in *On the Origin of Species* (see, e.g. Ayala 1977, 1994, 1994b; Ruse 1979, 1996).

- Enables the idea that students put forward their explanations and are in a position to modify them to acquire modern scientific knowledge. In this way, the study of the history of science will help them understand that some of the explanations they provide, though inaccurate, can provoke a conceptual change.
- Constitutes a strong source of suggestions about how the contents and concepts of a course must be organized according to their complexity and can be used to define the pertinent didactic sequences in the development of a topic.
- Finally, allows us to locate scientific and technological developments within the general outlook of the history of humanity, which is useful for understanding the link between a scientific approach and social problems (UNESCO 1999).

One of the authors of this chapter has promoted an initiative to include the history of science in the basic education curriculum of Latin America schools (Chamizo 1994, 2007).

69.3 The 1993 and 2006 Reforms and the Transformation of Science Teaching in Mexico

Mexico has constructed a significant and high-quality scientific and technological system over the last 20 years. However, this system is insufficient before the new challenges imposed by novel problems and international competition. For these reasons, our scientific and technological system must be consolidated and expanded in a very particular way: through the teaching of science and technology in the early stages of individual development. We must emphasize that the development of science and technology in Mexico has public institutions at its foundation. Any project that comes from the State will have as a starting point the cultural, scientific, professional and historical capital generated in said institutions.

Until a few decades ago, basic-level student education regarding science was concentrated on presenting a rigid structure of subjects which tended to promote the idea that science is a great deal of information that, when processed, offers scientifically correct answers about the phenomena in our surroundings. Thanks to the development in historical and philosophical studies of science, it is now thought that the disciplines that make up science were historically formed through posing problems, not the other way around.

69.3.1 The 1993 Reform

During the presidency of Carlos Salinas de Gortari (1988–1994), the Educational Modernization Programme (Programa para la Modernización Educativa) was proposed and enacted in 1993 (known as the 1993 Reform). It contained a diagnosis of the country's situation and proposed a deep structural change. This model implied radical structural changes and the innovation of practices to modify educational content, the ongoing training of teachers, the organization of different educational levels and the integration of basic education in one cycle that would include preschool and basic education (elementary and junior high).[6] All this in order to elevate the quality of education, to reduce backwardness and decentralize the education system.[7,8]

Methodological, conceptual and epistemological aspects were included in the 1993 Reform of the science curriculum and the study programmes for elementary and junior high schools, which meant an advance regarding the conception of modern science in national curricula. The new natural sciences programmes were based on a formative perspective according to the goal of helping students 'to acquire knowledge, capacities, attitudes and values that can be expressed by the development of a responsible relationship with the environment… and to educate children not as scientists in a disciplinary and formal way; instead, students are encouraged to observe, question, and formulate simple explanations about what happens in their surroundings' (Barraza 2001).

Thanks to this reform, there was progress regarding the teaching of science in basic education,[9] for not only elementary and junior high school curricula were modified but also new textbooks[10,11] and new materials were prepared for the

---

[6] Elementary or basic education includes compulsory preschool, primary and junior high education. Preschool lasts for 2 years (4–5 years old), primary education lasts for 6 years (6–11 years old) and junior high education lasts for 3 years (12–15 years old).

[7] On March 4, 1993, the Article 3 of the Constitution was amended, assigning a mandatory character to junior high school. This fact provoked one of the most important changes in the 70-year life of junior high school since its foundation. This reform was incorporated into the General Education Act (Ley General de Educación), enacted on July 12, 1993. In this way the government, through the Ministry of Public Education (Secretaría de Educación Pública, SEP), together with the states, committed to the decentralization of education, to 100 % coverage and to raising its quality levels.

[8] The SEP was founded in 1921 by the Mexican government. Since then, this ministry has designed the content of the national curricula for all subjects for basic education.

[9] The teaching of science in elementary school includes biology, physics and chemistry.

[10] In 1959 the SEP launched a new program, the Free-Text Program (Gilbert 1997), which established the National Commission for the Free Textbooks (Comisión Nacional de Libros de Texto Gratuitos, Conaliteg), and the production of the national textbooks for all basic education subjects, which are based on the national curricula. These textbooks, official and distributed for free, are still being handed out to every basic-level student, teacher and school (private and public, urban and rural) in the country, giving access to all basic-level students to education. These textbooks provide specific guidelines for each grade and are considered excellent sources of information.

[11] It is worth mentioning that some science educators were engaged in the production of the elementary textbooks around 1996 and added a good deal of history and philosophy of science to them.

teachers, with a focus that attempted to centre the teaching of science according to the modern ideas of the history and philosophy of science mentioned above.

Bonilla and colleagues (1997a, b) and Chamizo (2005) have documented this reform. The natural sciences' programme for primary school included five major topics: living beings; human body and health; environment and environmental protection; raw material, energy and change; and science, technology and society (STS). The STS dimension of teaching science corresponds to a large need of innovation in science education. As early as 1971 Jim Gallagher proposed a new goal for school science: 'For future citizens in a democratic society, understanding the interrelationships of science, technology and society may be as important as understanding the concepts and process of science' (Gallagher 1971, p. 337).

As is it outlined by Aikenhead (2003) in his synopsis on the origins and dispersion of this new approach of teaching science, the name STS was coined by John Ziman (1980) in a book titled *Teaching and Learning about Science and Society*. In spite of its title, the book consistently referred to STS in its articulation of the rationale, directions and challenges for STS in school science. It is important to mention that Aikenhead mentioned the following sentence about the relationship of history and philosophy of science with the STS scheme: 'A more comprehensive treatment of STS includes the internal social context (the epistemology, sociology and history of science itself) as well as the external social context of science' (2003, p. 63). It must be emphasized that the recent inclusion of STS in Mexican education means recognition of the importance of history and philosophy of science (Garritz 1994).

Peter Fensham (1985), in his famous paper *Science for All*, contributed directly to the evolution of STS by forging links between science education and technology education, embedded in social contexts relevant for all students. Fensham (1995) has mentioned in the Mexican *Chemistry Education Journal* that in 1984 the Science Council of Canada reported on a 4-year study of school science in that country. The title was 'Science for Every Citizen'. A year later the Royal Society in London published a manifesto, 'Science for Everybody', as part of a larger report on the public understanding of science. In 1988, Australia's Curriculum Development Centre put out a national discussion document entitled 'Science for All', and in 1989 the American Association for the Advancement of Science summarized phase 1 of its Project 2061 under the title *Science for All Americans.* Finally, before the Mexican reform, UNESCO and ICASE had launched 'Project 2000+: Scientific and Technological Literacy for All' (ICASE 1993).

In the Mexican reform of junior high school, the diverse methodologies of each one of the sciences (biology, physics and chemistry) were acknowledged, and the curriculum changed from 'natural sciences' to 'biology', 'physics' and 'chemistry'.

69.3.2 Biology: The Teaching of Evolution

For natural sciences in elementary education, it was established that biology (its first three topics: living beings, human body and health, environment and environmental protection), from the third to the sixth grade, should be taught from an evolutionary perspective. Evolution itself became a subject in the sixth grade.[12]

> Diverse themes with an evolutionary focus were introduced in the beginning of the third grade. For example, there is a discussion of plants' capacity to nourish themselves and how this relates to the oxygen that we breathe today, which comes from photosynthesis of plants that existed thousands of years ago […] Throughout the development of themes regarding the study of plants and animals, there are multiple references to the importance of adaptations that are a result of the evolution of the species […] In the fourth grade, the study of evolution is reinforced when, among many examples, students learn about the role of human beings in changing ecosystems. In the fifth grade the subject of "cells, one-cell and multi-celled organisms" is introduced. Fifth-graders also learn about the first grand division between one-celled organisms with a nucleus and one-celled organisms without a nucleus or bacteria. (Barahona and Bonilla 2009, p. 16)

The sixth-grade programme extensively included evolution: the origins of the earth, the transformation of ecosystems (throughout time and due to continental drift), fossils, the extinction of species, geological eras, Darwin and his book *Voyage of the Beagle*, the concepts of natural selection and adaptation, among others. This resulted in a fundamental transformation of the curriculum and textbooks, as previous materials had discussed knowledge about the origin of species in a purely descriptive manner. This change constituted a great challenge for the design and elaboration of the new third-to-sixth-grade Mexican textbooks (Barahona and Bonilla 2009).

As Shortland and Warwick (1989) have shown, historical case studies draw attention to the failures and disappointments that often follow long years of work or to the communal effort that goes into the production of new scientific knowledge. This viewpoint was particularly crucial for the teaching of evolution in elementary and junior high schools. The inclusion in the six-grade programme of Darwin's Voyage of the Beagle is an example of how historical case studies can show not only on evolution and Darwinism but also on the teaching of the nature of science, the scientific method and the role of evidence in science.

In sum, the 1993 curriculum and textbooks were an important leap forward and indeed a great advance over other educational systems that still question the value of including the Darwinian theory in elementary school.[13]

---

[12] This was already a requirement in the 1970s but only as a junior high school subject among many. For example, the discussion was limited to the study of fossils as evidence of life in the past, with illustrations that showed the gradual evolution of horses as well as the differences between contemporary humans and their ancestors; the references to Darwin were minimal (Barahona and Bonilla 2009).

[13] According to the 1993 Reform, the federal authorities launched a new curriculum including these new perspectives in 1997 for teacher's colleges; 4 years later, in 2001, the first group of elementary school teachers graduated with this training. However, there has been no evaluation as to whether the training truly is enabling them to teach natural sciences with an evolutionary focus or, even more importantly, if the students manage to develop an evolutionary mindset.

69.3.3 Chemistry and Its Social Benefits

In junior high school there were three courses in which chemistry was involved: in the first year 'introduction to physics and chemistry', in the second 'chemistry I' and in the third 'chemistry II'. A thorough revision of the curriculum changes and the teachers' training effort needed for this reform is detailed in Chamizo, Sánchez and Hernández (2006). The major theme in chemistry I is the identification of the particulate nature of matter until its concretion in Bohr's atomic theory. The third course is centred on energy and environmental topics (Chamizo 1992).

The most important change in the chemistry curriculum of the 1993 Reform surely was the focus on the STS dimension. The main purpose of the two last chemistry courses is quoted as being one where 'pupils preserve the main elements of basic culture, to enrich their vision of Mexico and the world and assess social benefits that represent the contribution of this science, as well as the risk of its inappropriate utilization' (SEP 1993, p. 95).

The six units in which the courses chemistry I and II were divided had the following names:

Unit 1. You and chemistry
Unit 2. Matter: its manifestations. Mixtures: its separation. Compounds and chemical elements
Unit 3. The discontinuous nature of matter
Unit 4. Water, dissolutions and chemical reactions
Unit 5. Burning fuel. Oxidations
Unit 6. Electrochemistry

The necessity to include environmental education topics is emphasized often. The following can be mentioned as examples: acid rain, ozone and low atmosphere contamination; management of industrial residues; sulphur and nitrogen oxides produced by internal combustion machines; chlorofluoroalkanes; and the ozone hole in the stratosphere. And the STS focus insists in integrating the same critical stance on everyday chemical products such as acids like vinegar, lemon juice, gastric juice; bases like antacids or drain cleaner; colloids like gelatin, mousse, mayonnaise or egg white; hydrocarbons like gasoline, candle, gas cooker, asphalt; and gases solubility like soda and fish tanks.

The introduction of historical facts and biographies of scientists is welcome, because 'science is not a mystery, but a product of human activity…It is not about fulfilling an encyclopaedic commitment, but about giving science a vitality focus' (Chamizo and Garritz 1993, pp. 136–7).[14] A relevant point of this reform is that an ambitious updated programme accompanied it for teachers, which included readings from various issues of history and philosophy of chemistry and physics (Chamizo et al. 2006). An interesting impact of the 1993 Reform in chemistry was documented by applying a 'chemistrymeter' to a set of students just finishing its secondary studies (Tirado et al. 2001).

---

[14] A couple of more references on the philosophical bases of this reform can be found in Chamizo (1994, 2001).

69.3.4 School Physics and Philosophy of Science

Like chemistry, physics had its curricular presence in three junior high school years: introduction to physics and chemistry, physics I and physics II, taught in the first, second and third grades, respectively. Some aspects of modern philosophy of science are clearly presented among general aims of the subject, such as:

1. The students should think about the nature of scientific knowledge and how it is generated, developed and applied (SEP 1993, p. 77).
2. Formulations of an alleged scientific method, unique and invariable and formed of successive phases should be avoided in teaching. That version of the method is hardly adequate for the students and does not correspond to the real steps which scientists follow in carrying out their work. It is more valuable that students have a vision according to which scientific knowledge production from systematic and rigorous procedures and from intellectual flexibility derive in a capacity to plan adequate questions and search for unconventional explanations (SEP 1993, p. 78).
3. Physics should be presented as a product of human activity and not as an accidental result of work of a few exceptional persons. To this aim, it is convenient to propose examples of scientific developments motivated by challenges and problems which appear in social life and to stress concrete cases in which scientific advances are results of the accumulative work of many people, although they may have worked independently and in different places (SEP 1993, p. 78).

The inclusion of physics' history is rightly suggested as a way to exemplify the nature of science: 'It is convenient to study and discuss biographies of important persons in physics history, not as an encyclopedic recount, but stressing the forms of reasoning, inquiry, experimentation and error correction which leaded to some relevant discoveries and inventions' (SEP 1993, p. 78).

Although the importance of philosophy and history of science is clearly stressed among the general aims of the physics' curriculum, it is not explicitly materialized and specified at the content level. Only three obligatory topics have this historical and philosophical perspective:

Physical view of the world
Analysis of the Galileo Galilei's experiments and their relevance in scientific work
The ideas of Copernicus, Galileo, Kepler, Newton and Einstein

Without clear curricular indications about philosophical and historical themes, further developments of the intended curriculum were left to the textbook authors. Common models of curricular processes in science education fall into three levels (Robitaille et al. 1993; Valverde et al. 2002):

1. Intended curriculum (aims and goals)
2. Potentially implemented curriculum (textbooks and other organized resource materials) and factually implemented curriculum (teachers' classroom strategies, practice and activities)
3. Attained curriculum (students' knowledge, ideas, constructs and schemes)

At the level of the potentially implemented curriculum and in the absence of further guidelines, historical themes can have very distinct and arbitrary presentations. This was the case in 15 authorized physics' textbooks, written according to the 1993 curriculum reform, where three famous experiments by Galileo had diverse presentations. Regarding the Pisa Tower experiment, five authors did not mention it, five authors described it in a relatively acceptable way and five authors treated it completely wrong. Namely, these last authors present it as an experiment in which times and positions of a body in free fall were measured exactly. Obviously, the authors ignored that such measurements were technologically impossible in Galileo's time. Precisely due to this impossibility, Galileo designed and carried out his groundbreaking inclined plane experiment!

Eleven authors did not mention the thought experiment, one author treated it properly by using Galileo's account of it and three authors presented it as a real experiment.

The inclined plane experiment also had diverse presentations in physics' textbooks. Five authors omitted to mention it; only two authors gave it a satisfactory treatment, while eight authors presented that historically important experiment either wrongly or incompletely.

As all authorized textbooks passed an expert evaluation by the Mexican Ministry of Public Education, the authors are not the only ones to blame. It means that real content and meaning of historical episodes should be disseminated among textbook authors and reviewers (maybe via workshops organized by educational authorities), especially when such episodes form part of the intended national curriculum's objective in order to give students a reliable information about how science works. Furthermore, for an adequate curricular impact in Mexican classrooms, a pedagogical analysis and implementation strategies of such historical episodes should be included in professional programmes for in-service and prospective teachers.

69.3.5 The 2006 Reform

During the presidency of Vicente Fox Quesada (2000–2006), the Junior High School Reform (Reforma de la Escuela Secundaria, RES) was undertaken by the federal government in the National Programme of Education (Programa Nacional de Educación) 2001–2006. It established that the 'Mexican State must offer democratic, national, intercultural, secular and mandatory education that favours the development of the individual and his community, as well as a sense of belonging to a multicultural and multilingual nation, and the awareness of international solidarity of the educated' (SEP 2006).

In 2000, Mexico dedicated 100 dollars to each one of its elementary students. This amount that can be compared with the 600 dollars spent in the USA, the 130 USD used for Argentineans and the 220 USD spent by Chileans (Chamizo et al. 2006).

The designing group of this reform spent a lot of sessions deciding the order in which the three natural sciences should be presented. The decision was centred in a

Table 69.1 2006 Reform. Secondary science contents

Sciences I (emphasis in biology)
Unit I. Biodiversity: result of evolution
Unit II. Nutrition as the base for health and life
Unit III: Respiration and its relation with the environment and health
Unit IV. Reproduction and the continuity of life
Unit V. Health, environment and quality of life
Sciences II (emphasis in physics)
Unit I. The description of movement and force
Unit II. Laws of motion
Unit III: A model to describe the structure of matter
Unit IV. Internal structure of matter manifestations
Unit V. Knowledge, science and technology
Sciences III (emphasis in chemistry)
Unit I. The characteristics of materials
Unit II. Properties of materials and their chemical classification
Unit III: Materials transformation: chemical reaction
Unit IV. Formation of new materials
Unit V. Chemistry and technology

Project 2061 document (AAAS 2001) that recommended biology first, physics second and chemistry third. The natural sciences programmes were called sciences I, II and III, in accordance with the three grades in junior high school. In the first grade the students take sciences I (biology), in the second sciences II (physics) and in the third sciences III (chemistry). The scientific contents of the 3 years of education are represented by the titles of its units in Table 69.1.

At the end of each unit or at the end of the course, projects are developed by each student or groups of students as a good way to develop competencies because ‘it favors integration and application of knowledge, skills and attitudes, giving the study a social and personal meaning’ (SEP 2006).

Often, the projects select aspects related with the everyday life of students and their interests. Projects must favour attitudes as curiosity, creativity, innovation, informed scepticism and tolerance towards different ways of seeing the world. Each project requires the consideration of historical aspects as well as experimental work, and at the end students have to share their results. This objective was based on Stone and Tripp (1981), SATIS (1986) and Chamizo and Garritz (1993).

Some studies made a diagnosis of the scientific curriculum in basic education in Mexico prior to the 2006 Reform. For example, among the problems detected in the teaching of science, Flores and Barahona (2003) found a split between elementary and junior high schools; problems associated with the conception, development and decoupling of science and technology; the inadequate incorporation of the history of science in some subjects; little exploration of values and, finally, that science had not been inserted into the frame of culture.

It is necessary to emphasize that the teaching of science and technology was not marginalized, but played an important role in the focus of the curricula and new textbooks. This reform, despite requiring improvement in the future regarding the teaching of science and technology, promises to be a necessary step for the consolidation of a national science and technology programme and establishes graduation profiles related to science. Some of the most sensible decisions are mentioned below:

> The history of science employs a line of argument and reasoning to analyse situations, identify problems, formulate questions, pass judgment and propose diverse solutions. The teaching of science selects, analyses, evaluates and shares information from diverse sources and takes advantage of technological resources within reach to deepen and widen the learning of science in a permanent manner. It employs knowledge acquired with the purpose of interpreting and explaining social, economic, cultural and natural processes, as well as to make decisions and act, individually or collectively, to promote health and care for the environment as ways to improve the quality of life. (SEP 2006)

Also, the RES mentions the need to take advantage of information and communication technologies in general education, and particularly in scientific education, for this is a powerful tool in the socialization of knowledge and holds important pedagogical and didactic possibilities. The RES starts with a broader vision of technological education, understood as a social, cultural and historical process, which allows students to develop knowledge to solve problematic situations in an organized, responsible and informed manner, as well as to meet needs of a diverse nature. Technological education must contribute to the training of students as competent and critical users of the new technologies, in order to face the challenges of today’s society.

It was established in this reform that scientific training is a goal for boosting cognitive development, strengthening individual and social values in teenagers as well as learning to reflect, exercising curiosity and using informed critique and scepticism, which will allow them to decide and, when necessary, act. A fundamental epistemological focus of the teaching of science relates to the understanding of science and technology as historical and socially constituted activities performed by men and women from different cultures.

The way in which different cultures in Mexico explain and construct knowledge about nature constitutes a practice that arrives nowadays through knowhow, folk knowledge and techniques in which different logics for building knowledge are mixed. From there, it is important to know, recognize and value such perspectives (SEP 2006). The history of science, according to this point of view, gained particular importance in the modification of the study programmes.

The RES expects that when students finish junior high school:

1. They have broadened their conception of science, of its processes and interactions with other areas of knowledge, as well as its social and environmental impact, and value in a critical manner their contributions for the betterment of the quality of life of people and the development of society.

2. They have advanced in the understanding of explanations and arguments of science about nature and use them to better understand the natural phenomena of their surroundings, as well as to place themselves within the scientific and technological development context of their time. This implies that students build, enrich or modify their first explanations and concepts, as well as develop abilities and aptitudes that provide them with elements to configure an interdisciplinary and integrated vision of scientific knowledge.
3. They can identify the characteristics and analyse the processes that separate living beings, relating them to their personal, family and social experience, to know more about themselves, their potential, their place among living beings and their responsibility in the way they interact with their surroundings, so they can participate in promoting health and the sustainable conservation of the environment.
4. They progressively develop knowledge that favours the understanding of concepts, processes, principles and the explanatory logic of science and its application to diverse common phenomena. They should go deeper into basic scientific ideas and concepts and establish relationships among them so they can build coherent explanations based on logical reasoning, symbolic language and graphic representations.
5. They have boosted their capacity to handle information, communication and social coexistence. This implies learning to value diverse ways of thinking, discern between founded arguments and false ideas and make responsible and informed decisions, at the same time as strengthening self-confidence and respect for themselves and for others (SEP 2006).

69.3.6 Biology: The Essence of Evolution

In the case of biology, evolution and genetics appear as central pillars in its teaching. For this reason the teaching of biology in junior high school starts with integrative theories such as evolution by natural selection, referring to biology as a scientific discipline from a historical perspective. Many references to Darwin's construction of the theory are taught in order to focus the attention of students on the historical and epistemological aspects of this discipline. Following the elementary school curriculum, the teaching of evolution is reinforced in junior high school. Regarding genetics, Mendel's laws are taught using his famous experiments with peas to show the manifold aspects of the experimental method in biology.

According to the RES in junior high school, as in elementary school, the scientific learning method must be encouraged, not as the scrupulous monitoring of a series of steps to be followed mechanically (observation, hypothesis, experimentation), but as a flexible and applicable method for the construction of knowledge over a whole course, not only in biology but also in other subjects such as physics, chemistry and geography.

In the 1993 Reform, the changes to the content of the educational programmes represented progress considering the epistemological and pedagogical references, but social aspects remained much diluted. For this reason the intercultural perspective was included in the RES, based on the idea that the diversity of forms in which human beings build knowledge about nature is of a cultural, social and historical order. In our country, cultural diversity has been the source of multiple ideas, explanations and interpretations, which have enriched, complemented and sometimes strained the development of scientific and technological knowledge. It is very important to recognize the diversity of ways to interpret the world and how, in some cases, these have aided scientific developments (like herbalism), or native technological development, which is beneficial to communities' relationship with the environment (SEP 2006).

69.3.7 School Physics and Philosophy of Science

In general terms, the 2006 curriculum framework is much better articulated than the 1993 version to move school physics activities closer to authentic science practices (Chinn and Malhortam 2002). Namely, it is planned that students gain basic scientific culture, in resonance with actual constructivist views on school science learning, through various (and even ambitious) learning tasks:

(a) Select and relate, in a causal and functional way, adequate variables to explain phenomena.
(b) Establish relationships between fundamental concepts which make it possible to construct coherent interpretative schemes in which logical reasoning, symbolic language and graphical representations are involved.
(c) Pose questions, elaborate hypothesis and inferences and construct explanations of some ordinary physical phenomena.
(d) Carry out experiments, get information from diverse sources, use different means to make measurements, analyse data and look for alternative solutions.
(e) Communicate, listen to and discuss ideas, arguments, inferences and conclusions related to physical concepts and their applications in scientific, technological and social contexts (SEP 2006, pp. 65–66).

Explicit curricular spaces and times for such activities are dedicated to develop projects which students are supposed to carry out at the end of each of five blocks.

As in the 1993 curriculum, philosophical aspects of science are not among explicit general aims. Nonetheless, the historical development of physics, the nature of scientific knowledge construction, the integration of science and relationships between science, technology and society are supposed to be taken into account, together with different students' comprehension levels, conceptual problems and previous ideas, as criterions for selection, organization and continuity of the course content (SEP 2006, p. 66)

Such intention is clearly visible in the general structure of the physics course parts, summarized in the Table 69.2.

At the content level, historical and philosophical aspects of physics have a more visible presence than in the 1993 curriculum. Besides the Galileo's

Table 69.2 Relationships between physics domains, representational means and thematic blocks

Physics domain	Elements for representations of physical phenomena	Thematic blocks
Study of motion	Descriptive schemes	Block I. Description of the changes in nature
Analysis of forces and changes	Relationships and sense of mechanism	Block II. The forces. Explanations of the changes
Particulate model	Images and abstract models	Block III. Interactions of matter. A model for description of unseen
Atomic constitution	Images and abstract models	Block IV. Manifestations of internal structure of matter
Universe, interaction of physics, technology and society	Integrated interpretations and relationships with environment	Block V. Knowledge, society and technology

contribution to science (SEP 2006, p. 76), students are supposed to know not only about motion laws but also about the role Newton had in the development of scientific thinking (SEP 2006, p. 86). In addition, the historical development of kinetic model and the atomic model of matter (SEP 2006, p. 102) are mandatory contents.

However, the main difference regarding the 1993 curriculum is the central place given to scientific models. Students are supposed to learn about the general role of models in the construction and verification of scientific knowledge. This intention is explicitly stated in the subthemes (what is the use of models, the models and the ideas they represent, the role of models in science) and curricular goals (the role of models in explanations of physical phenomena, as well as their advantages and limitations).

Nevertheless, the features of scientific models presented might be misleading for the expected learning results. It is said that students should 'recognize that a model is an imaginary and arbitrary representation of objects and processes which include rules of its function and is not the reality itself' (SEP 2006, p. 94). Strictly speaking, although theoretical models in physics are abstract representations and not copies of reality, they are not arbitrary because their predictions must be in concordance with observations.

Regarding textbook presentations of Galileo's work, the situation is similar as it was with the 1993 curriculum. Majority of authors treat the inclined experiment either inadequately or wrongly (Miguel Garzón and Slisko 2010).

69.3.8 Chemistry Presented as Projects and Models

Following the proposal expressed in the course of physics regarding the use of models, an important emphasis on the features of models in scientific explanation is made in chemistry (Gilbert and Boulter 1998, Chamizo 1988). Teachers generally ignore the issue, as exposed in educational research whose products have been books (Chamizo and García 2010) and articles on training experiences (Justi et al. 2011) and the reconceptualization of the subject (Chamizo 2011).

Nevertheless, this reform took into serious account Jensen's proposition of three Chemical Revolutions (1998) and explicitly mentioned them even in the programme (SEP 2006). The types of projects mentioned in the curriculum are scientific, technological and of citizenship. At the end of the units, the following projects must have been developed:

Unit I. The characteristics of materials
Projects related with separation methods to purify substances from mixtures. Or the work developed in a salt installation and its impact to the environment. Discussion, evidence research, information and communications technology (ICT) use, measurement, information analysis, interpretation of results and argumentation are to be fostered.

Unit II. Properties of materials and their chemical classification
The suggested projects point to the identification of elements of the human body, its health and environmental implications.

Unit III: Materials' transformation: chemical reactions
Projects related with soap production, energy release and absorption by human body are suggested.

Unit IV. Formation of new materials
In the framework of sustainability, the projects suggested have to do with avoiding corrosion or with fuel efficiency.

Unit V. Chemistry and technology
These technologic projects are developed to integrate the four previous units. The following topics are suggested: synthesis of an elastic material, Mexican contributions to the chemistry of fertilizers and pesticides, cosmetic products, Mesoamerican construction materials, chemistry and art and the importance and impact of petroleum products.

69.3.9 The Recent Years

During the Presidency of Felipe Calderón Hinojosa (2006–2012), the Mexican authorities launched a new reform in 2009 that has not yet concluded. It began in 2009 with curriculum changes to the first and sixth grades, in 2010 the changes affected the second and fifth grades, and finally in 2011 they included all the grades of elementary school. In July 2011, the SEP announced a new junior high school reform that intended to link all basic education levels (preschool, elementary and junior high school) and the production of new textbooks accordingly. Much of the progress made in previous reforms regarding the introduction of history and philosophy of science in science education was lost, particularly in the production of the most recent science textbooks.[15]

This new reform, called the Integral Reform for Basic Education (Reforma Integral de la Educación Básica, RIEB), intended to give continuity to the curricula and study programmes of all basic education. The organization of the subjects remained the same, although big changes were introduced in the natural sciences curricula (SEP 2011).

The national standards for science are the acquisition of scientific literacy, the use of scientific and technological literacy, development of skills associated with science and attitudes towards science. It does not mention the use of the history and philosophy of science in the teaching of sciences, and in the case of sciences I (biology), many topics about evolution are missing, but most importantly biology is not taught from an evolutionary perspective. The references to Darwin are very few, the Voyage of the Beagle is not mentioned, and fossils are seen as evidence of living beings in the past (not as relatives of present organisms). Although the topic of biodiversity is seen as the result of evolution, little is said about the processes that make up biological diversity and the evolutionary history of organisms. The teaching of biology in this reform is descriptive in comparison with the two previous ones.

69.4 Conclusion

We have tried to illustrate how science and technology are essential and at the same time constitutive parts of the modern society known as the knowledge society. Their importance demands, on one hand, reflection on the impact and scope of knowledge and, on the other, the modification of the educational agenda to make scientific and technological knowledge available to everyone. This strategy goes beyond the introduction of natural sciences as mandatory subjects; it implies a different focus on the selection, organization and sequencing of contents and the way to work with them.

It is decisive to collaborate in the change of the public perception of science and technology. In knowledge societies it is necessary that citizens have a positive attitude towards science and technology. This means that they have scientific and technological literacy that allows them from an early age to understand the potentials, benefits and risks of technoscientific products. This way, citizens, as well as local, municipal or federal officials, can make informed decisions before the problems technological changes produce in society take effect.

In this sense, the educational reforms in Mexico, the 1993 Reform and the RES, manifest the significance that the history and philosophy of science have had in the conception of teaching of science. Particularly, evolution and STS in Mexican education constituted an important advancement. It is worth saying that the

---

[15] These two reforms (2009 and 2011) are so recent that it is impossible for us to make an evaluation that provides a comparison with regard to the reforms referred to in this document.

introduction of the history and philosophy of science into the formal science curriculum in Mexico took the country some steps forward and some backward. For instance, the 1993 natural sciences programme for elementary education was more progressive regarding the history and philosophy of science than the 2006 programme for junior high education, and contrary to these advances, the 2009–2011 Reform lacked the teaching of science from a historical perspective and the evolutionary one regarding biology. This is to say that in the latest reform 2009–2011, the history and philosophy of science in relation with the teaching of biology is absent. We must wait for results to modify glitches and consolidate progress.

Ana Barahona is full-time Professor at School of Sciences of the National Autonomous University of Mexico, UNAM. She followed undergraduate studies on biology and graduate studies on history and philosophy of biology at the UNAM. She made postdoctoral studies at the University of California, Irvine. In Mexico, as one of the pioneers in the historical and philosophical studies of science since 1980, she founded the area of Social Studies of Science and Technology at the School of Sciences of the UNAM. Some of her interests focus on the history and philosophy of evolution and genetics (especially in Mexico), and in the relationship between epistemology and science teaching, and science education. She has published more than 80 specialized articles and book chapters, several research books and textbooks on biology and history and philosophy of science for elementary and middle school (among which the Mexican free textbook of natural sciences edited by the Education Ministry have been published to date more than one hundred million copies) and also for college education. She has been President (2009–2011) of the International Society for the History, Philosophy and Social Studies of Biology and Associated Editor of the journal *History and Philosophy of the Life Sciences*; currently she is a member of the editorial board of *Biological Theory* and a member of the editorial committee of *Almagest, History of Scientific Ideas* and *Science & Education*. She has been technical advisor of the National Institute for the Assessment of Education in Mexico for the period 2002–2010. Currently she is a Council Member of the Division of History of Science and Technology of the International Union of History and Philosophy of Science and has been recently acknowledged as a Corresponding Member of the International Academy for the History of Science.

José Antonio Chamizo is full-time Professor at the School of Chemistry of the National Autonomous University of Mexico, UNAM. Since 1977 he has taught over 100 courses from high school to Ph.D. and published over one hundred refereed articles in chemistry, education, history, philosophy and popularization of science. His BS and MS degrees were in chemistry from the National University of Mexico and his Ph.D. from the School of Molecular Sciences at the University of Sussex. He is author or coauthor of over 30 chapters in books and of more than 50 textbooks and popularization of science books among which the Mexican free textbook of natural sciences, coordinated by him and edited by the Education Ministry which have been published to date more than one hundred million copies.

Andoni Garritz is full-time Professor at the School of Chemistry of the National Autonomous University of Mexico, UNAM, where he teaches and researches ‘Didactics of Chemistry’, ‘Structure of Matter’ and ‘Science and Society’. He studied chemical engineering at UNAM and got his Ph.D. with a stay in the Quantum Chemistry Group at Uppsala University, Sweden, where he received the Hylleraas’ Award. He has been giving lectures for 40 years at different levels, from high school to postgraduate. He is a consultant of UNESCO, coordinating seven chemistry experimental education projects in Latin America. His most relevant books are *Chemistry in Mexico: Yesterday, Today and Tomorrow* (UNAM, 1991); *From Tequixquitl to DNA* (Fondo de Cultura Económica, 1989); *Atomic Structure: A Chemical Approach*; and *You and Chemistry* and *University Chemistry* (Pearson Education 1986, 2001, 2005). He is the founder Director of the Journal *Educación Química* that now has 23 years of circulation, and it is indexed by Scopus.

Josip Slisko (B.Sc. in physics, M.Sc. in philosophy of physics, Ph.D. in philosophical sciences) teaches courses on physics and mathematics education at Facultad de Ciencias Físico Matemáticas of the Benemérita Universidad Autónoma de Puebla. His research interests include student explanatory and predictive models of physical phenomena, student strategies for solving untraditional physics and mathematics problems, presentation of knowledge in textbooks and design of learning sequences which promote cognitive development of students. Josip Slisko is author or coauthor of 80 journal articles and 12 physics textbooks. Since 1994 he joins the Sistema Nacional de Investigadores (National System of Researchers), a programme of Mexican Government through which scientific production of one is evaluated and a stipend is paid to recognized scientists. He is a member of American Association of Physics Teachers and serves in editorial boards of various educational journals (*Latin American Journal of Physics Education*, *European Journal of Physics Education*, *Metodicki ogledi* and *Eureka*). Since 1993, every last week in May, he is the president of the committee which organizes an international workshop called new trends in physics teaching.

Chapter 70
History and Philosophy of Science in Science Education, in Brazil

Roberto de Andrade Martins, Cibelle Celestino Silva,
and Maria Elice Brzezinski Prestes

70.1 Introduction

This paper addresses the context of emergence, development, and current status of the use of history and philosophy of science in science education in Brazil. Its main scope is the application of this approach to teaching physics, chemistry, and biology at the secondary school level.

The first Brazilian researches and projects along this line appeared in the decade of 1970, although before that time it is possible to find scattered claims of the relevance of history and/or philosophy of science in science teaching. From the decade of 1980 onwards, the importance of this approach became widely accepted, and the subject became a common theme of educational dissertations and theses, appearing with a considerable frequency in papers presented at conferences on science education and published in educational journals. Since 1998, the use of history and

philosophy of science was included among the government recommendations for secondary school science teaching in Brazil. Nowadays, this is an important line of research in graduate programs on science and mathematics education. However, the actual use of this approach in secondary education is still a desideratum.

Before entering in the main subject, this paper will present a short overview of the development of philosophy of science, history of science, and science education in Brazil, especially from 1960 onwards.

70.2 Philosophy of Science

The main development of philosophy of science in Brazil, in the twentieth century, began after the creation of the University of São Paulo (USP) in 1934. From its very inception, this university established a practice of bringing to Brazil foreign researchers to help starting new disciplines and research lines. In the case of philosophy, the main foreign professors were French: Jean Maugüe, from 1935 to 1943; Giles Gaston Granger, from 1947 to 1953; Martial Guéroult, from 1948 to 1950; Claude Lefort, from 1955 to 1959; and Gérard Lebrun, from 1960 to 1966 and from 1973 to 1980 (Hopos 2000). There were other strong influences, too. For instance, in 1942, Willard Van Orman Quine spent a few months in Brazil. However, the main influence was French, and Guéroult's approach to history of philosophy dominated the University of São Paulo for decades (Lefebvre 1990).

During his short stay at the University of São Paulo, Quine learned Portuguese and wrote in this language his book *O Sentido da Nova Lógica* (*The Meaning of the New Logic*), published in Brazil in 1944 (Quine 1944; Stein 2004, p. 376).[1] However, Granger was the main reference for philosophy of science at USP, for a long time. His first book was published in Brazil, in Portuguese, in 1955: *Lógica e Filosofia das Ciências* (*Logic and Philosophy of Science*) (Granger 1955).

Notwithstanding those precedents, philosophy of science would only begin to bloom in Brazil in the 1970s (Salmerón 1991). At the University of São Paulo, the main Brazilian professors who began to develop this line of research were Oswaldo Porchat Pereira da Silva and João Paulo Monteiro. Monteiro, a specialist in Hume (Monteiro 1967), was a strong influence in the development of philosophy of science at USP, attracting new philosophers to this field and creating in 1979 the journal *Ciência e Filosofia* (*Science and Philosophy*).

Oswaldo Porchat, who had studied with Victor Goldschmidt in France, wrote a Ph.D. thesis on Aristotle, but obtained a broad acquaintance with philosophy of

---

[1] Quine stayed in 1942 at the *Escola Livre de Sociologia e Política* (*Free School of Sociology and Politics*), which at the time was an "autonomous complementary institution" of the University of São Paulo. At that time, one of the few Brazilian scholars who could interact with him on equal grounds was the philosopher of logic Vicente Ferreira da Silva, who published an important book on logic in Brazil, *Elementos de Lógica Matemática* (*Elements of Mathematical Logic*) (Silva 1940), and later became a Heideggerian.

science (Silva 1967). Although his first connection was with French history of philosophy, he also had a postdoctoral stage at the University of California, Berkeley (1969–1970). In 1975 Porchat left the University of São Paulo to found the Philosophy Department at the State University of Campinas (Unicamp) and the Center for Logic and Philosophy of Science (CLE) at the same university. This center was a main influence in the development of philosophy of science, in Brazil, organizing meetings and publishing two journals: *Manuscrito* (*Manuscript*), since 1977, and *Cadernos de História e Filosofia da Ciência* (*History and Philosophy of Science Notepads*) since 1980. The Philosophy Department at Unicamp started the first Brazilian graduate program on logic and philosophy of science.

Leônidas Hegenberg, after graduating in mathematics, physics, and philosophy in Brazil, spent two years working with Alfred Tarski at the University of California (1960–1962). Returning to Brazil, he completed his Ph.D. in philosophy at the University of São Paulo, in 1968 (Hegenberg 1968). During most of his professional life, he taught mathematics, logic, and philosophy of science at the Technological Institute of Aeronautics (ITA). For that reason, he never supervised any M.Sc. or Ph.D. student. However, he published many papers and books and was highly influential in Brazil. Besides that, he kept up to date with the development of philosophy of science abroad and translated about 60 books to Portuguese, including works by Karl Popper, Paul Feyerabend, Max Weber, Wesley Salmon, Mario Bunge, Derek J. de Solla Price, Charles S. Peirce, and others.

In Rio de Janeiro, a strong tradition in philosophy of science began with the arrival of the Brazilian researchers Raul Ferreira Landim Filho and Oswaldo Chateaubriand Filho, in the 1970s. Chateaubriand obtained his Ph.D. in 1971, at the University of California, Berkeley, on ontology and semantics (Chateaubriand Filho 1971). After teaching at Cornell University from 1972 to 1977, he returned to Brazil, where he finally settled at the Catholic University of Rio de Janeiro (PUC-RJ). Landim, who obtained his Ph.D. at Louvain (Landim Filho 1974), also arrived to Rio at about the same time and was influential in the development of philosophy of science at the Federal University of Rio de Janeiro (UFRJ). Another important philosopher of science, Alberto Oscar Cupani, born in Argentina, obtained his Ph.D. at Córdoba in 1974, moving to Brazil in 1977 (Cupani 1974). He first worked at the Federal University of Santa Maria (UFSM) and then settled at the Federal University of Santa Catarina (UFSC).

Around 1980 the area of philosophy of science was well established in Brazil and had attained an international standard of research. There are currently 12 graduate programs in philosophy of science, several journals, and regular meetings over the country.

70.3 History of Science

History of science, in Brazil, developed later than philosophy of science. Up to 1970 there were few universities with regular courses on history of science (in general) or history of specific scientific disciplines. Those who taught history of science had no specific training in this discipline; they were commonly senior scientists who had a broad cultural background, such as Mario Schemberg and Francisco Magalhães Gomes (physics), Antonio Brito da Cunha (biology), Leopoldo Nachbin (mathematics), and Simão Mathias (chemistry).[2] Up to the 1970s, works on history of science written by Brazilian authors were, in general, descriptive and laudatory accounts of Brazilian researchers and institutions. One of the best productions of this period was a book organized by Fernando de Azevedo, *As ciências no Brasil* (*Sciences in Brazil*), published in 1956.[3]

Research on the history of Brazilian science gradually improved. In 1971 the graduate program of the History Department of the University of São Paulo (USP) established the first research line on history of science. The main focus was the study of Brazilian science, although the group has also produced research and supervised dissertations and theses on the conceptual history of international science. In 1979–1981 they published the three-volume work *História das Ciências no Brasil* (*History of Sciences in Brazil*), organized by Mário Guimarães Ferri and Shozo Motoyama (Ferri and Motoyama 1979–1981).

One stimulus to the study of history of Brazilian science was the expectation that it could help to develop scientific policies. In Rio de Janeiro, the sociologist Simon Schwartzman, who had obtained his Ph.D. in political science at the University of California, Berkeley (Schwartzman 1973), developed an ambitious project to study the Brazilian scientific community. He conducted a large series of interviews with leading Brazilian scientists and in 1979 published the analysis of this work in an influential book: *Formação da Comunidade Científica no Brasil* (*The Development of the Scientific Community in Brazil*) (Schwartzman 2007).

In 1982 the *Sociedad Latinoamericana de Historia de las Ciencias y la Tecnología* (SLHCT) (*Latin American Society of History of Science and Technology*) was founded in México, with the participation of Brazilian historians of science. In the next year, the group of the University of São Paulo created the *Sociedade Brasileira de História da Ciência* (SBHC) (*Brazilian Society of History of Science*) (Motoyama 1988; Bassalo 1992). This association soon began to organize biennial meetings (beginning in 1986) and in 1985 started the publication of the first Brazilian journal devoted to the history of science.

The largest research institution in history of science, in Brazil, is devoted to the study of Brazilian medicine and related subjects: *Casa de Oswaldo Cruz*, in Rio de Janeiro (founded in 1986). Another important institution is the *Museu de Astronomia e Ciências Afins*, MAST (*Museum of Astronomy and Related Sciences*), founded in the same year.

Historical researches on Brazilian science had no impact in science teaching, because the curriculum of the scientific disciplines does not include any topic related to the development of national science.

The Brazilian researches on the history of international science followed another line of development that is more difficult to track down. Diverging from the

situation that occurred in philosophy of science, the main stimulus was not the contact with foreign researchers. However, there have been some influential foreign scholars, such as Michel Paty, who spent several periods at the University of São Paulo and also supervised Brazilian students in France.

Around 1980, several scattered scholars who taught history of mathematics, physics, chemistry, and biology began to devote a larger effort to the study of history of science. At this time, there were no graduate courses in Brazil where one could obtain the adequate training for research in the history of international science. Although they had no specific training in this field, they began to produce better research by employing primary sources and to stimulate younger scientists to dedicate themselves to this field. Among other researchers of this generation, we can cite Ubiratan D'Ambrosio and Guilherme de La Penha (mathematics), Aécio Pereira Chagas and Carlos Alberto Lombardi Filgueiras (chemistry), and Roberto de Andrade Martins and Penha Maria Cardozo Dias (physics).[4] Two philosophers who began to devote themselves to the history of science in this period should also be mentioned: Pablo Mariconda and Carlos Arthur Ribeiro do Nascimento (Mariconda 2003; Nascimento 1995).

In 1985, a series of annual meetings on history of science was started at the State University of Campinas, and in 1990 a first attempt was made to establish a graduate program on history of science at the same university. However, internal problems suspended this development. Although dissertations and theses on history of science had been produced at several Brazilian institutions, since the decade of 1980, the first specific graduate course on history of science was created at the Catholic University of São Paulo (PUC-SP) in 1997, the second at the Federal University of Bahia (UFBA) in 2000 (with strong emphasis in science teaching), and the third one at the Federal University of Rio de Janeiro (UFRJ) in 2002. There is also a graduate program on the history of medicine, at Casa de Oswaldo Cruz, Rio de Janeiro, founded in 2001.

From the late 1980s onwards, the number of researchers in conceptual history of science who had received specific training gradually increased in Brazil. Among them, we may cite Olival Freire Jr. and Antonio Augusto Passos Videira (physics); Anna Carolina Regner, Lilian Al-Chueyr Pereira Martins, Gustavo Caponi, and Nelio Bizzo (biology); Ana Maria Alfonso-Goldfarb (chemistry); and Sérgio Nobre (mathematics).[5] Most of them received part of their training abroad. In the decade of 1990, research in history of conceptual science attained an international level, in Brazil.[6]

The strong development of the history of mathematics led to the creation of the *Sociedade Brasileira de História da Matemática* (SBHMat) (*Brazilian Society for the History of Mathematics*) in 1999. This society has its own journal and regular

biennial meetings. In 2000 the *Associação de Filosofia e História da Ciência do Cone Sul* (AFHIC) (*South Cone Association for Philosophy and History of Science*) was created, bringing together scholars from Brazil, Argentina, Chile, and Uruguay. This society gave a new impetus to interchanges between historians and philosophers and stimulated the formation of thematic groups. The idea of creating AFHIC was initially discussed at the *First Meeting of Philosophy and History of Science of the South Cone*, which took place in 1998 at the Federal University of Rio Grande do Sul (UFRGS), Brazil, under the aegis of the Research Group on Philosophy and History of Science (GIFHC), from that university.

The development of research in history and philosophy of biology started with the first *Meeting of Philosophy and History of Biology* that occurred in 2003, in São Paulo, followed by a series of annual conferences. During the fourth meeting, in 2006, the *Associação Brasileira de Filosofia e História da Biologia* (ABFHiB) (*Brazilian Association for Philosophy and History of Biology*) was founded and in the same year began the publication of the journal *Filosofia e História da Biologia*. It is possible to notice a conspicuous interest on the use of history and philosophy of science in biology teaching in the meetings and publications of this society.

Although history of physics is a very strong research area in Brazil, no specific society for its study has been created, neither for the history of chemistry.

The largest part of the researches in history and philosophy of science developed in Brazil had no impact in science education. High-level researches in those fields, written in specialized jargon, published in professional journals or in foreign languages, are seldom read by Brazilian science educators. Besides that, philosophers and historians of science hardly ever write textbooks or popular works in this country.

70.4 Science Education in Brazil

This section will present an overview of the development of science education in Brazil, in the second half of the twentieth century. Although science education can be understood as including all levels from elementary school to graduate studies, the focus here will be the Brazilian equivalent to high school or secondary education, that is, the 3 last years of basic education, preceding higher education. We may confine our analysis to this level, since most researches on the use of history and philosophy of science in science teaching, in Brazil, deal with secondary education.

Before describing the historic qualitative changes in science education in Brazil, it is relevant to remark that in this country only a very small part of the population was able to attain secondary education in the first half of the twentieth century and that this proportion has been increasing up to the present. Around 1995, the Brazilian gross secondary school enrolment ratio reached about 50 %, being much worse than that of other South American countries, such as Argentina (76 %), Chile (73 %), and Uruguay (81 %) (Rigotto and Souza 2005). This unpleasant situation was one of the reasons for the educational reform announced by the Brazilian government in 1996, which proposed several policies for improving the enrolment ratio of students between 15 and 17 years old at secondary schools. The huge quantitative increase of the secondary school enrolment was achieved with a significant deterioration of material conditions and teaching and learning quality. Improving the overall quality of education is the current challenge for educational authorities in the country. Nevertheless, let us go back and review the development of science teaching in that country.

Until the Second World War, the main educational influence in Brazil was European (especially French). Textbooks were translated, laboratory equipment used in demonstrations was imported, and educational methods were copied. Secondary education was not compulsory and there were few public schools offering this level. In general, only people who intended pursuing higher education would enroll in high school. Access to the universities requires both the completion of secondary education and approval in competitive entrance examinations.

Shortly after the end of the war, several changes occurred. The American influence expanded very fast; there was a stronger concern with the scientific development of the country; and there arose the first attempts to develop national teaching projects. The prevalent view was that scientific development was a necessity for industrial and economical development of the country; and the government of President Getúlio Vargas was deeply concerned with those issues.

Two important institutions were created in 1951: the *National Research Council* (CNPq), to stimulate and support scientific researches, and the *Campaign for the Improvement of Personnel for Higher Education* (CAPES), belonging to the *Ministry of Education and Culture* (MEC), with the aim of improving the level of university professors by the creation of graduate courses and international exchange.[7]

In the early 1950s, under the leadership of Isaías Raw, the recently founded *Brazilian Institute of Education, Science and Culture* (IBECC) produced the first laboratory kits developed in this country. This was a nice innovation in education in Brazil, because it introduced low-cost equipment that could be used by students (not for class demonstrations, as the former imported equipments) and had a strong positive influence in science teaching. In the late 1960s, the industrial dimensions of the production of laboratory equipment led to the creation of the *Fundação Brasileira para o Desenvolvimento de Ensino de Ciências* (FUNBEC) (*Brazilian Foundation for the Development of Science Teaching*) to cope with the large-scale production of teaching materials (Villani et al. 2009; Nardi 2005).

In 1965, six centers of science for teaching training and development of educational materials were created in Brazil: in Pernambuco (CESINE), Rio Grande do Sul (CECIRS), Minas Gerais (CECIMIG), Rio de Janeiro (CECIGUA), São Paulo (CESISP), and Bahia (CECIBA). The leaders of those centers were trained at IBECC, in 1966 (Nardi 2005). Most of these initiatives, however, were not maintained to the present day.

---

[7] The names of these institutions were later changed to *National Council for Scientific and Technological Development* and *Coordination of Improvement of Personnel of Higher Education*, respectively, although their acronyms were maintained.

Nowadays many critics point out that the empiricist view behind those projects was naïve and inadequate – and that is a correct appraisal (Villani et al. 2009; Nardi 2005). However, positive features cannot be denied. Brazilian science educators had been deeply influenced by John Dewey's work, especially his book *How We Think* (1910). This book was first translated into Portuguese in 1933 and republished in 1953 and 1959. Following Dewey's ideas, science educators were striving to provide a more active involvement of students with science, attempting to develop their reasoning capacity and critical attitude (Freire Jr. 2002).

Notice that, parallel to any innovatory trends, there was a conservative undercurrent in Brazilian education. Essentially, in the 1960s as now, science and mathematics teaching in secondary schools was grounded upon books written with a very simple aim: to train the students to obtain a good performance at the universities' entrance examinations.[8]

In 1961, an educational reform increased the weight of scientific disciplines in both elementary and secondary education. In 1964 a military *coup d'état* and the beginning of a long dictatorship in Brazil (1964–1985) led to deep changes in the educational system, but the previous impetus to improve science education was maintained. The educational influence of the United States increased, and an agreement established in 1965 between the Brazilian *Ministry of Education and Culture* (MEC) and the *United States Agency for International Development* (USAID) led to introduction of many North American educational materials in Brazil (Nardi 2005).

It is well known that in the late 1950s, due to the Cold War between the United States and the Soviet Union, five outstanding American educational projects were developed to improve the teaching of mathematics, physics, chemistry, and biology at high school level: *Physical Science Study Committee* (PSSC), *Biological Science Curriculum Study* (BSCS), *Chemical Bond Approach* (CBA), *Chemical Education Material Study* (CHEMS), and *School Mathematics Study Group* (SMSG). Those projects were introduced in Brazil in the decade of 1960 and they had a strong impact. The textbooks were translated and the experimental kits were reproduced, with small adaptations, by *Instituto Brasileiro de Educação, Ciência e Cultura* (IBECC) (*Brazilian Institute for Education, Science and Culture*). In the United States, about 200,000 students used the PSSC and CHEMS materials, 600,000 used the BSCS texts, and 1,350,000 students used SMSG books. In Brazil, about 400,000 copies of PSSC volumes were published and a similar number of copies of BSCS (Barra and Lorenz 1986, *apud* Nardi 2005). Other foreign products, such as the Nuffield Foundation project, were also translated and used in Brazil (Krasilchik 1992; Villani et al. 2012).

---

[8] Universities are free to create any kind of entrance examination. The most traditional one is called "vestibular" and assesses the student's knowledge on the subjects studied in the secondary school. Except the last decade exams conducted by University of Campinas (UNICAMP), "vestibular" in general has a strong inertia regarding the style and content. In recent years, the performance at *Exame Nacional do Ensino Médio* (ENEM) (*High School National Exam*), designed to assess scientific contents and other competencies as reading and comprehension, has also been used as entrance examinations by over 300 institutions. This is a nonmandatory exam, attended by 5.8 million students in 2012.

In the American projects, the use of the "scientific method" was emphasized, with a strong empiricist bias. Those approaches were typical in science education during the 1960s and were still influential in the 1970s, in Brazil.

The reception of the American projects among secondary school teachers was not altogether positive. They had difficulties in dealing with the new methods and contents (Villani et al. 2009). In January 1970 the *Sociedade Brasileira de Física* (SBF) (*Brazilian Physics Society*) sponsored the *First National Symposium on Physics Teaching*. The PSSC project was much criticized, and the participants of the event reached the conclusion that it was necessary to develop Brazilian projects to elaborate new textbooks and laboratory materials. The first initiatives were already on the move, at the University of São Paulo (USP) under the leadership of Ernest Hamburger and at the Federal University of Rio Grande do Sul (UFRGS), by initiative of Marco Antonio Moreira (Oliveira and Dias 1970). Educators such as Pierre Henri Lucie, who was one of the main supporters of the introduction of PSSC in Brazil, were already looking for alternatives. In 1969 Lucie started the publication of an original line of physics textbooks for secondary schools, with a deeper conceptual discussion, using cartoons: *Física com Martins e eu* (*Physics with Martins and I*) (Lucie 1969).

70.5 Brazilian Research and Projects in Science Education

There were new educational reforms in Brazil in 1968 (higher education) and 1971 (elementary school and secondary education). In 1972 the *Ministry of Education and Culture* (MEC) started the *Project of Expansion and Improvement of Education* (PREMEN) to promote an enhancement of education with the development of teaching materials for science and mathematics in the country and adapted to the national context, also providing adequate teaching training for the use of those materials. In the early 1970s, stimulated by government guidelines and financial resources, the formation of research groups and the development of science teaching projects started up in Brazil (Barra and Lorenz 1986).

At that time, three physics teaching projects were under way: *Physics Teaching Project* (PEF) at the University of São Paulo (coordinated by Ernst W. Hamburger and Giorgio Moscati), *Self-Instructive Physics* (FAI) by the *Group of Studies in Physics Teaching Technology* (Fuad Daher Saad, Kazuo Watanabe, Paulo Yamamura, and others), and *Brazilian Project for Physics Teaching* (PBEF) at FUNBEC (organized by Rodolpho Caniato, Antonio Teixeira Jr., José Goldenberg). The three projects were student centered, without expositive classes. The first project had a stronger experimental emphasis which generated a difficulty for its application at secondary schools that could not acquire laboratory equipment. In the two other projects, experiments were secondary activities to illustrate knowledge that had already been learned using self-instructive techniques. The FAI project included passages describing the history of physics, written by Shozo Motoyama. Its books sold 490,000 copies, between 1973 and 1976 (Flores et al. 2009).

In the early 1970s, educational projects on chemistry and biology were also developed in Brazil: *The National Project for the Teaching of Chemistry* (1972), developed by the *Northeast Coordination of Science Teaching* (CECINE), and the Project of Biology Applied to Secondary School (1976), an initiative of the *São Paulo State Center for Science Teaching* (CESISP) (Barra and Lorenz 1986, *apud* Nardi 2005). The most relevant educational initiative in mathematics was developed under the guidance of Ubiratan D'Ambrosio at the State University of Campinas (Unicamp): *New Materials for the Teaching of Mathematics*, for the fundamental school level.

In 1972 the *Brazilian Foundation for Science Teaching* (FUNBEC) and the publisher *Abril Cultural* launched a new project called *Os Cientistas* (*The Scientists*): a series of 50 experimental kits for the study of chemistry, biology, and physics, which were sold in newsstands. Each edition contained an experimental kit, instructions for performing the experiments, and the biography of a famous scientist related to the experiment (Newton, Pasteur, Lavoisier, etc.). This initiative was planned by two professors of University of São Paulo, Isaías Raw and Myriam Krasilchik, and was coordinated by the latter. The project was highly successful and sold three million units (a mean of 60,000 copies of each edition). It was later translated into Spanish, English, and Turkish and sold in other countries (Krasilchik 1990). Although the project included material related to the history of science (the biographies), this was circumstantial: the authors of the biographies and of the experimental kits had no interaction,[9] and the emphasis of the project was an empiricist approach to science.

The development of the area of science and mathematics education along the last decades in Brazil can be noticed in the beginning of regular conferences, founding of societies, creation of journals devoted to school teachers and researchers, and establishment of graduate courses.

The first regular series of congresses devoted to physics education, called *Simpósio Nacional de Ensino de Física* (SNEF) (*National Symposium on Physics Teaching*), started in 1970, one decade before the creation of general congresses devoted to science education in general or to the teaching of the other scientific disciplines such as *Encontro Nacional de Ensino de Química*, ENEQ (*National Meeting on Chemistry Teaching*) (1982); *Encontro Perspectivas do Ensino de Biologia*, EPEB (*Meeting on Perspectives of Biology Teaching*) (1984), discontinued; *Encontro de Pesquisadores de Ensino de Física*, EPEF (*Meeting of Researchers of Physics Teaching*) (1986); *Encontro Nacional de Educação Matemática*, ENEM (*National Meeting on Mathematics Teaching*) (1987); *Encontro Nacional de Pesquisa em Ensino de Ciências*, ENPEC (*National Meeting on Research in Science Teaching*) (1997); *Colóquio de História e Tecnologia no Ensino de Matemática*, HTEM (*Conference of Technology and History of Mathematics Teaching*) (2002); and *Encontro Nacional de Ensino de Biologia*, ENEBIO (*National Meeting of*

---

[9] Roberto de Andrade Martins, one of the authors of this paper, can safely state that the two sides of the project were widely independent, because of his personal involvement with the project: he was the author of some of the biographies of *Os Cientistas*.

Biology Teaching) (2005). Most of these are biennial meetings. There are also many regional and local relevant conferences. Besides that, for a long time other general scientific and educational conferences have also included sessions on science and mathematics teaching.

Since 1976, when *Boletim Gepem* devoted to mathematics education was created, many other Brazilian journals on general and specific areas of science education appeared along the years, for instance, *Revista de Ensino de Física, Caderno Catarinense de Ensino de Física, Química Nova na Escola, Investigações em Ensino de Ciências, Ciência & Educação, Revista Brasileira de Pesquisa em Educação em Ciências, Revista de Ensino de Biologia,* and *Alexandria: Revista de Educação em Ciência e Tecnologia,* among many others.

Several scientific societies began to sponsor educational activities, and later on, specific associations were created. The *Sociedade Brasileira de Física* (SBF) (*Brazilian Physical Society*) established a Commission for Physics Teaching in 1970. In 1988 the *Sociedade Brasileira de Educação Matemática* (SBEM) (*Brazilian Society of Mathematical Education*) was founded. In 1997 the *Associação Brasileira de Pesquisa em Educação em Ciências* (ABRAPEC) (*Brazilian Association for Research in Science Education*) and the *Associação Brasileira de Ensino de Biologia* (SBEnBio) (*Brazilian Association of Biology Teaching*) were founded. There are no specific societies related to the teaching of chemistry and physics. In both cases, there are teaching divisions belonging to the corresponding national scientific societies.

Although there were educational initiatives in the several disciplines, physics took the leadership in the establishment of a definite enterprise for the improvement of science teaching. In 1967 the graduate program in physics of the Federal University of Rio Grande do Sul (UFRGS) established the area of physics teaching. The first specific graduate course in science teaching was created in Brazil in 1973, at the University of São Paulo (USP), as a joint initiative of the Physics Institute and the Faculty of Education; about 20 years later, the areas of chemistry and biology were also introduced. There was also an attempt to establish the area of physics teaching in the graduate program created at the Catholic University of Rio de Janeiro (PUC-RJ) in 1967, but it did not succeed. In 1975, the first graduate course in mathematical education started at the Catholic University of São Paulo (PUC-SP) and the second one in 1984, at the Rio Claro campus of the São Paulo State University (UNESP). The latter was the first one to offer a Doctor degree, in 1993. Other graduate courses in science education started at the Federal Rural University of Pernambuco (1995), Federal University of Rio de Janeiro (1995), and at the Bauru campus of UNESP (1997) (Moreira 2004). From 1972 to 1995, 572 theses and dissertations had been finished on science and mathematics education, including those that have been produced at other graduate programs. There was a very fast increase of graduate programs on science and mathematics education from 2000 to 2010, reaching a total of 78 programs in the area at the end of 2010 (CAPES 2010).

In 1999 the first Brazilian graduate program devoted to history and philosophy of science and science education was founded in Bahia State: the *Graduate Program* *in Teaching, Philosophy and History of Sciences* (EFHC). It is an interinstitutional program between Federal University of Bahia and State University of Feira de Santana, with master and doctorate courses (Freire Jr. and Tenório 2001).

70.6 History and Philosophy of Science in Science Education

According to Susana de Souza Barros, it is possible to find several uses of history and philosophy of science in different periods, in Brazil. In the decade of 1970, history of physics was regarded as an important component of the teaching training. The transposition of this historical knowledge to physics teaching at the secondary school level was not discussed, however. During the 1980s, the study of concept formation and conceptual change led to the combined use of psychological, epistemological, historical, and sociological approaches. There were researches using classroom experimentation, and the new line of attack was regarded as useful for the training of physics teachers. Nevertheless, it was not directly applied to introduce educational changes at the secondary school level. During the next decade (1990), there was a strong emphasis on the relation of science teaching and the education for citizenship, using the science, technology, and society approach (STS). The idea that science educators should teach not only science but also about science (i.e., the inclusion of a metascientific level) launched a new use for history and philosophy of science in physics teaching (Martins 1990). Towards the end of the last century, the Ministry of Education established new educational guidelines recommending the use of history and philosophy of science at the secondary school level (Barros 2002).

70.6.1 The Beginning: Physics

It was already remarked that physics was the first area where science education research began, in Brazil. Let us see how the use of history and philosophy of science in physics teaching started and was understood in this discipline, in the early period. This occurred at the University of São Paulo (USP), and therefore our focus, here, will be that institution.[10]

History of physics was taught from the very beginning of the establishment of its undergraduate physics course, at USP. One of the most influential early professors who taught this discipline was Mário Schenberg (1914–1990), a Brazilian physicist with strong political interests. He was a member of the Brazilian Communist Party before this political organization was banned from the Brazilian politics, and he was

---

[10] The other early group, at the Federal University of Rio Grande do Sul (UFRGS), did not develop this line of research at first, and its leader complained in 1970 that there was no one available at that institution to teach history of physics (Oliveira and Dias 1970, p. 106).

twice elected deputy of the State of São Paulo (1946 and 1962). He was arrested twice for his political involvement. He was highly influential, and his interest for Marxism and history of science was shared by many other physicists.

Several books on history of science with a Marxist outlook were well known in Brazil, around 1970 (Azevedo and Costa Neto 2010). Friedrich Engels' *Dialectics of Nature* had been translated into Portuguese in 1946, with John Burdon Sanderson Haldane's introduction, and it was republished in 1962 and 1964. It was a very popular book among physicists, at USP, in the 1960s and 1970s. John Desmond Bernal's works were also very influential. Bernal's *Science in History* (1954) was translated in México, in 1959, and in Portugal, in 1965. Both translations, as well as the original English version, were familiar to many Brazilian physicists. Boris Hessen's "The Socio-economic Roots of Newton's Principia" was also well known and highly praised. The Marxist play writer Bertolt Brecht's version of Galileo's life was very popular in Brazil, and parallels were drawn between his struggle with the Catholic Church and the scientists' resistance to the Brazilian military government of that period. The play was enacted in São Paulo, in 1968, with the priests using olive dresses – olive being the color used by soldiers, in Brazil. At that time, the study of the relations between science, history, politics, society, etc. was regarded as a means to denounce the alleged neutrality of science, leading the students to have a more critical view of the scientific endeavor, and also critical of the Brazilian political situation of the time. Students were regarded as citizens that should be educated to deal, among other things, with the political and economic forces surrounding them.

This was a very influential trend, in the early development of the use of history (and sociology) of science in science education in Brazil (Villani et al. 2010). Even now, long after Marxism had become outmoded, its inspiration is still present as an undercurrent in the *science, technology, and society* (STS) approach, in Brazil, although the recent generation is not aware of its early history.

Besides this politically motivated interest in the history of science, there was another view about its educational value. In 1970 the *Harvard Project Physics* was being introduced in Brazil, and its strong use of history of science was described by Giorgio Moscati, who emphasized the motivational aspect of the historical and humanistic approach (Oliveira and Dias 1970). There was a widespread belief that mere contact with history of science could enhance the motivation of students and also to improve their learning of scientific concepts.

This was also, seemingly, the opinion of Pierre Lucie, who taught physics at the Catholic University of Rio de Janeiro. As mentioned above, Lucie had been a strong supporter of the PSSC project in Brazil. However, in 1970 he was devoting himself to other educational projects. In that year he delivered a course on the history of mechanics during the first *National Symposium on Physics Teaching* that occurred in São Paulo. He published a book on this subject in 1978, called *Gênese do Método Científico* (*Genesis of Scientific Method*). This work was not an adaptation of history of physics for science teaching; it was just a plain work on history of science, written by an outstanding educator (Lucie 1978). Several papers published in the early volumes of *Revista de Ensino de Física* (*Journal of Physics*

Teaching), such as those authored by José Maria Filardo Bassalo, were also devoted to the presentation of historical information, without any special application to physics teaching.

Although there was a widespread interest in the history of science at the USP group from its very beginning, its effective influence only began to produce noticeable results in the late 1970s. Let us notice some instances of works produced by the group. In 1978 Amélia Império Hamburger produced a study of physics textbooks, including "the concept of physics and science" among the several features that should be analyzed. In the same year, she wrote a historic and philosophical analysis of mechanics and electricity to help circumventing conceptual learning difficulties. In 1979, João Zanetic wrote a work on the role of history of physics in education. Ernest Hamburger and Joaquim Nestor de Morais presented a historical analysis of the concept of electrostatic potential, comparing it with its textbook presentation. Amélia Hamburger proposed a project using historical examples for teaching physical concepts. In 1980 Alberto Villani started a research on the history of the theory of special relativity. In 1981 Amélia Hamburger began the development of a series of didactic booklets, and one of them contained texts on "science, technology, and society." Zanetic and José D. T. Vasconcellos proposed the introduction of the Popper-Kuhn debate in physics teaching (Gama and Hamburger 1987).

From 1979 onwards, the USP group invited several foreign visitors who delivered courses on history and philosophy of physics: Marcelo Cini (in 1979 and 1980), William Shea, in 1979, and Michel Paty, in 1982, (Gama and Hamburger 1987; Robilotta et al. 1981).

In 1981 Alberto Villani published the first paper, in Brazil, that referred to the so-called spontaneous concepts, mentioning the recently published works (1979) of Laurence Viennot and John William Warren on this subject. Viennot was invited to Brazil and delivered a course on this subject at USP, in 1981. In the following years, this became a very strong line of research of the USP group, involving several researchers such as Villani, Jesuina Lopes de Almeida Pacca, Anna Maria Pessoa de Carvalho, and Yassuko Hosoune, together with graduate students. Three M.Sc. dissertations on this subject were finished between 1982 and 1985 (Gama and Hamburger 1987).

Independently of the USP group, Arden Zylbersztajn, who was a professor at the Federal University of Rio Grande do Norte (UFRN) and had strong interest in history and philosophy of science, started in 1979 his doctoral studies in the University of Surrey, under the guidance of John Gilbert, and began the study of physical "spontaneous concepts," publishing his first paper on this subject (with Michael Watts) in 1981 (Gilbert and Zylbersztajn 1985; Watts and Zylbersztajn 1981). After his return to Brazil, in 1984, Zylbersztajn continued to develop this research line at UFRN and, after 1987, at the Federal University of Santa Catarina (UFSC).

The comparison between the students' concepts and the historical evolution of science became one of the main uses of history of science in physics education, in Brazil, for a significant period. This trend was soon linked to the work of Piaget and Garcia (1982) on the parallels between psychogenesis and history of science.[11]

---

[11] There were some critics of this kind of parallelism, for instance, Franco and Colinvaux 1992.

The study of the students' previous concepts and of the strategies to produce conceptual change became more and more sophisticated during the decades of 1980 and 1990, with the development of analogies between science education and the ideas of Feyerabend, Laudan, Bachelard, and other philosophers of science.

In the 1990s, educational experiments developed by Anna Maria Pessoa de Carvalho and Ruth Schmitz de Castro introduced historical texts in secondary school classrooms, to explore the similarity between the student's concepts and the ideas presented in those texts (Castro and Carvalho 1995). Many students were stimulated by noticing the similarity between their own concepts and those of important scientists. The discussion of historical texts also helped in producing a conceptual change in the students. The texts and the description of their use were later incorporated in teachers training courses, showing a specific useful application of history of science in science teaching.

There were other different trends. Towards the end of the 1970s, another group of the University of São Paulo, including Luis Carlos Menezes, João Zanetic, and the graduate students Demétrio Delizoikov Neto and José André P. Angotti, endeavored to apply the educational ideas of Paulo Freire (Freire 1970) to science teaching, linking some of his ideas to Thomas Kuhn's views. Delizoikov, Angotti, and other educators put to practice this proposal during a stay in Guinea-Bissau, one of the countries where Freire had worked during his exile from Brazil, after the 1964 military *coup d'état* (Delizoikov Neto et al. 1980). The dissertations of Delizoikov and Angotti, supervised by Menezes, were completed in 1982 (Delizoikov Neto 1982; Angotti 1982). Although Kuhn's ideas had been a starting motivation, the stronger emphasis of those works is neither historical nor philosophical.

Menezes also supervised Alexandre José Gonçalves de Medeiros, who finished in 1984 his M.Sc. dissertation on the sociocultural and economic influences that acted upon the development of physics up to the end of the seventeenth century. As pointed out above, this line of social history of science had been strongly influenced by Marxist authors.

Although several researchers of USP involved with history and philosophy of science participated in projects that produced educational materials for secondary schools, those projects did not include the use of history and philosophy of science.

Since that time, the uses of history, philosophy, and sociology of science in teaching are a thematic area in graduate programs and conferences on physics and science teaching. There are several research groups devoted to this topic exploring different approaches and methodologies. Along the last years, several books and papers were published on this topic, attesting that history and philosophy of physics is embedded within physics education in Brazil since its very beginning. One strong trend is that several authors hold that the study of historical episodes of science can help students to form a more accurate view of the nature of science and to learn about scientific concepts.[12]

(2010), Silveira and Peduzzi (2006), and Teixeira et al. (2012), Silva and Moura (2012).

70.6.2 Chemistry

The development of a research line in chemistry teaching, in Brazil, had its beginning at the University of São Paulo (USP). When this university was created, in 1934, a German chemist called Heinrich Rheinboldt (1881–1955) was invited to begin the chemistry department. Rheinboldt had a strong interest in the education of teachers and also in history of chemistry, having published in 1917 a study about Johann Baptist van Helmont. He was very influential in stimulating the study of history of chemistry and chemical education (Schneltzler 2002). Under his inspiration, Simão Mathias devoted himself to the history of chemistry, especially after retiring from the Chemistry Institute, in 1972, when he became a professor at the History Department and was responsible for the discipline of history of chemistry.

In the decade of 1960, Ernesto Giesbrecht, of USP, became involved with the translation and adaptation of the North American projects of chemistry (CBA, CHEMS). In the next decade, a group began to form at the Chemistry Institute of USP, under the leadership of Luiz Roberto de Moraes Pitombo and Maria Eunice Ribeiro Marcondes, devoted to the formation of chemistry teachers. José Atílio Vanin also began the development of activities of popularization of chemistry, with the help of students. Those activities finally led to the creation of the Group of Research in Chemical Education (GEPEQ), which is very active. In the decades of 1980–1990, the approach of the group was contributing to chemistry teaching at the secondary school level, with an emphasis in experimentation, relations between chemistry and everyday life, and the use of cognitivist proposals (Ausubel, Piaget).

Although there were some early activities related to chemistry education, such as those described above, the expansion of the area is strongly linked to the creation of the *Sociedade Brasileira de Química* (SBQ) (*Brazilian Chemical Society*) in 1978. During the first meeting of this society, there was a session devoted to the discussion of chemistry teaching, and interest in this line increased in the following years. The journal of this society *Química Nova* (*New Chemistry*) started the publication of papers on chemistry teaching in 1980.

At the same time, at the south edge of the country (State of Rio Grande do Sul), a series of regional annual meeting started in 1980: the *Encontro de Debates sobre Ensino de Química* (EDEQ) (*Meeting of Debates on Chemistry Teaching*), organized by Attico Chassot. In 1988 the *Brazilian Chemical Society* founded its Teaching Division and in 1982 began the series of biennial conferences called *Encontro Nacional de Ensino de Química* (ENEQ) (*National Meetings on Chemical Teaching*). In 1995 the *Brazilian Chemical Society* founded a new journal: *Química Nova na Escola* (*New Chemistry at School*), the main target of this publication being secondary school chemistry teachers.

One of the strongest lines of research in the 1990s was the study of previous concepts of students and the way of dealing with those ideas. The earlier idea that those spontaneous concepts should be transformed or replaced by the standard scientific concepts was given up by Eduardo Fleury Mortimer, who developed a new approach of conceptual profiles, inspired by Gaston Bachelard (Mortimer 1995, 2000).

The new attitude allows the students to keep their previous concepts, being aware of the difference between the scientific and popular cultures.

During the decade of 1990 the analysis of the epistemological beliefs of chemistry teachers led to the conclusion that they adopted a naïve empiricism and transmitted this attitude to their students. It became evident that the training of chemistry teachers should include not only the knowledge of chemistry but also its historical and epistemological features, as well as the social, economic and political context of the development of this science (STS approach).

Contributions from history and philosophy of science are not very common in research on chemistry teaching. Among several different approaches that can be found, we can point out an emphasis in the analysis of epistemological views presented in textbooks and by students and teachers and proposals of strategies to provide a more adequate view on the nature of science using historical studies of chemistry. The science, technology, and society approach is also deemed important, and historical examples (such as the development of dyes) are suggested to introduce this issue. Some of the works also claim the improvement of learning of chemical concepts using a historical approach.

Many works that cannot be classified as "research in chemistry education" should also be mentioned. From the 1990s onwards, several Brazilian chemists have published popular books on history of chemistry (Vanin 1994; Chassot 1994) and many papers on specific subjects. More recently, Juergen Heinrich Maar is producing a three-volume work on the history of chemistry (two parts have been published: Maar 2008, 2011). The production of papers on specific episodes of the history of chemistry has also provided the Brazilian teachers with some nice works that can be put into use in their educational practice.[13]

70.6.3 Biology

As noticed above, the BSCS project was introduced in Brazil in the 1960s. Besides many innovations, the project included a historical study of biological concepts. However, this did not lead to any stimulus for the development of studies of history of biology applied to science education in Brazil, at that time.

Brazilian educational projects related to biology teaching were produced from the decade of 1960 onwards. They attempted to produce textbooks with new content, together with laboratory materials. Until the next decade, the main concern was the production of teaching materials and the teaching training, and there was no concern with educational research in biology. Around 1990 the area begins to produce researches on spontaneous concepts of students and teachers and on the use of history and philosophy of science.

---

[13] Among the articles devoted to the use of history of chemistry on education see, among others, Bagatin et al. (2005), Baldinato and Porto (2008), Chassot (2001), Farias (2001), Flôr (2009), Oki (2000), Paixão and Cachapuz (2003), Porto (2004), Tolentino and Rocha Filho (2000), and Vidal et al. (2007).

In the cases of physics and chemistry, the respective scientific institutes of the University of São Paulo (USP) played a relevant role in the development of the area of science education. The national physical and chemical societies also gave strong support to this area. In the case of biology, the situation was widely different. Research in biology education was strongly developed at the Faculty of Education of USP, especially under the leadership of Myriam Krasilchik – not at the Institute of Biology.[14] Besides that, since a *Brazilian Society of Biology* never existed, there was no association that could support the area. Indeed, there are several biological societies in Brazil, related to genetics, zoology, etc. but none that could assume the improvement of biology teaching as its concern.

In 1984 the Faculty of Education of USP began a series of conferences, called *Encontro Perspectivas do Ensino de Biologia* (*Meeting on Perspectives of Biology Teaching*). Although they did not have a national character, those events attracted researchers from other institutions, starting a process of organization of the area. The creation of the *Sociedade Brasileira para o Ensino de Biologia* (SBEnBio) (*Brazilian Society for the Teaching of Biology*) in 1997 led to a decentralization of the events, with regional conferences on biology teaching promoted at other states. The first *National Meeting for the Teaching of Biology*, organized by SBEnBio, occurred only in 2005. The journal of this society, *Revista de Ensino de Biologia* (*Journal of Biology Teaching*), started in 2007. In 2008, the *Brazilian Association for Philosophy and History of Science* (ABFHiB) created a Commission for Biology Teaching and produced a series of case studies for application in secondary schools.[15]

Up to 1996 the number of theses and dissertations on biology teaching was very small. In the last years of the twentieth century, there was a strong increase, parallel to the creation of the *Brazilian Society for the Teaching of Biology*, but not as an effect of this society (Teixeira et al. 2009). Around 1990 the area begins to produce researches on spontaneous concepts of students and teachers and on the use of history and philosophy of science.[16] The first works on the STS approach in biology education appeared a few years later.

Works using this approach usually stress the importance of introducing history of science in biology teaching to present science as a human construct, subject to mistakes, influenced by external factors, producing provisory knowledge. They denounce the inductive view of science, the idea that biology was produced by a few bright minds, and the view that science is the attainment of absolute truth. Those researches also emphasize the need to introduce history and philosophy of science in the teaching training. The STS approach is also recommended, adding the environment dimension. Besides discussion and recommendations, there are several

---

[14] It is worth mentioning that the situation has changed along the last 5 years. Due to the Teacher Education Program of USP, the Institute of Biosciences hired professors on biology teaching and history of biology, and new similar positions for science teaching were created in other science institutes (Universidade de São Paulo 2004).

[15] Andrade and Caldeira (2009), Batisteti et al. (2009), Bizzo and El-Hani (2009), Carmo et al. (2009a), Brandão and Ferreira (2009), Martins (2009a), (2009b), and Prestes et al. (2009).

[16] Among others: Bastos (1998), Cicillini (1992), Martins (1998), Slongo (1996).

works that include the production, application, and analysis of teaching activities using history and philosophy of biology.[17]

70.7 National Educational Guidelines

The relevance of history and philosophy of science in science teaching was officially recognized, in Brazil, at the end of the twentieth century. In 1996, the Brazilian Ministry of Education (MEC) began an educational reform. The first official step was the promulgation of the *Leis de Diretrizes e Bases* (*Law of Brazilian Education Guidelines and Bases*), followed by a *Resolution* of the National Education Council that established the *National Curricular Guidelines for Secondary Education*, in 1998 (Brasil 1996, 1998). This *resolution* describes, in its tenth article, some of the abilities and competencies that the students should acquire in their study of mathematics and natural sciences, including:

> (a) To understand the sciences as human constructs, recognizing that they develop by accumulation, continuity or paradigm rupture, correlating the scientific development to the transformation of society; […] (i) To understand the relation between the development of the natural sciences and the technological development and to associate the different technologies to the problems that they intended to solve; (j) To understand the impact of the technologies associated to the natural sciences in the student's personal life, in the production processes, in the development of knowledge and in social life (Brasil 1998, p. 4–5).

The first of those items is directly related to the nature of science issues, associated to history and philosophy of science, and the other ones, to history of science and technology and science-technology-society issues. That document did not suggest any other roles for history and philosophy of science.

A group of educators, invited by the Ministry of Education, produced in 1997–1998 a document explaining how the general guidelines should be applied by teachers: *Parâmetros Curriculares Nacionais para o Ensino Médio* (PCNEM) (*National Curriculum Parameters for Secondary Education*) (Brasil 1997). This was followed by a more detailed complement, published in 2002: *PCN+Ensino Médio: Orientações Educacionais Complementares aos Parâmetros Curriculares Nacionais* (*Educational Complementary Guidelines to the National Curriculum Parameters*) (Brasil 2002). The sections of those two official documents concerning mathematics, physics, chemistry, and biology point out, at several places, the relevance of history and philosophy of science to science education.

The elaboration of the two documents on natural sciences and mathematics was coordinated by Luís Carlos de Menezes. For each discipline, the group provided

---

[17] Among others, see Almeida and Falcão (2005), Batista and Araman (2009), Baptista and El-Hani (2009), Bastos and Krasilchik (2004), Caldeira and Araújo (2010), Carmo et al. (2009b), Carneiro and Gastal (2005), El-Hani and Sepulveda (2010), El-Hani et al. (2004), Goulart (2005), Justina (2001), Leite (2004), Meglhioratti (2004), Pereira and Amador (2007), Rosa and Silva (2010), Santos (2006), Santos et al. (2012), Scheid et al. (2005), and Slongo and Delizoikov (2003).

specific instances of the use of history and philosophy of science, especially related to the issues of the nature of science and science, technology, and society. The previous official documents understood the contextualization of science education in the sense of the cognitive approaches to education. The group interpreted the contextualization in a much broader sense: "In general terms, contextualization in science education includes competencies related to the insertion of science and its technologies in a historic, social and cultural process and the recognition and discussion of practical and ethical features of science in the contemporaneous world […]" (Brasil 2002, p. 31). The *Educational Complementary Guidelines* (PCN+) provide a large number of specific instances that can be used by teachers in addressing those issues.

Besides those features related to history and philosophy of science, there were many other new proposals that cannot be described here. If the guidelines could be put into practice, they would greatly improve science teaching, in Brazil. Unfortunately, more than 10 years after the educational reform and the publication of the above-described documents, one cannot recognize any definite transformation in science education. Secondary school science teachers could hardly understand all the changes that have been recommended. One can attribute this failure to a lack of effective public policies to improve the school system as a whole. One central aspect that is rarely addressed is the fact that teachers had no adequate training for coping with the new proposals that could help them to attain the new aims.

70.8 Conclusion

Nowadays, the relevance of history and philosophy of science in science education is widely recognized in Brazil. Although the effective classroom practice has not yet incorporated its use, the official educational guidelines are stimulating its development. A large number of books and papers, theses and dissertations, have been produced on this theme. This approach is an important trend in graduate programs and in educational conferences.

Two specific meetings on this subject were held in Brazil, in 2010: the *8th International Conference for the History of Science in Science Education* (ICHSSE) and the *1st Latin American Conference of the International History, Philosophy and Science Teaching Group* (IHPST-LA), with the participation of about 150 researchers (Silva and Prestes 2012). Some specific books on the subject, providing information and suggestion of classroom activities, were published in recent years. There is also an increasing international and regional collaboration.

The Brazilian contributions in this area are not well known worldwide, because most works are published in Portuguese. Although it is relevant to participate in global conferences and projects and to publish in other languages that can reach a wider public abroad, it is very important to produce works in Portuguese for local use. The vast majority of secondary school teachers cannot understand books and papers in English, and even those who can do it prefer reading works published in our national language.

There are several types of publications in this area. The academic ones (those presented at conferences or published in scholarly journals and books) describe the several approaches and defend (or criticize) their use; they review researches published abroad and in Brazil; they analyze textbooks; they present surveys of the concepts of students and teachers concerning the nature of science and other subjects related to history and philosophy of science; they provide information about history and philosophy of science that can be used in science teaching; they describe specific developments of syllabi, texts, and other educational materials applying history and philosophy of science in education; they report classroom experiments using history and philosophy of science; and they present proposals of new initiatives in the field, such as teaching learning sequences based in application of history and philosophy of science in science education (Peduzzi et al. 2012). Nowadays, the focus of history and philosophy of science in science education is the discussion of the nature of science and science, technology, society and environment issues. The uses of history of science to improve the learning of scientific ideas, to increase the motivation of students, its intrinsic cultural value, and other uses that were proposed in the 1970s and 1980s, are nowadays seldom mentioned.

The vast majority of authors of the abovementioned academic works are either university professors or graduate students. Most of this production will never reach in-service science teachers, but might be used for preservice teaching training at the university, or in specific courses for in-service teachers.

On the other hand there are publications targeted at in-service teachers (and also students), such as the journals that have already been described (*Revista do Professor de Matemática*, *Química Nova na Escola, Física na Escola*) and books. Those journals have a wide penetration, but their function is mainly informative. It is doubtful that they have contributed to effective changes in science teaching, because they only contain short papers. There are many books on history and philosophy of science published in Portuguese. However, teachers interested in this subject usually read popular, out-of-date books that reproduce the old views on the nature of science.

There is a shortage of educational materials using history and philosophy of science in the secondary school classroom. As described above, as a rule science textbooks include mistaken information about history and philosophy of science. There have been attempts to produce supplementary texts on history of science for use by students, but their effective utilization has been very limited.

Much remains to be done in consolidating the effective use of the history and philosophy of science in Brazilian science education. Nevertheless, it is possible to say that there is a solid ground, in research and graduate courses; there is clear official interest in the use of history and philosophy of science in education; there is a growing awareness and interest in this subject by teachers; there is a pressure by the Ministry of Education upon publishing houses in order to improve the quality of history views on nature of science in textbooks; in a nutshell, there are nice conditions to take off and fly. Of course, government support is essential and is sometimes unavailable; but many initiatives that depend only on researchers can start a snowball effect and produce important results.

It is necessary to consider the complexity of the education system in order to create a successful implementation of history and philosophy of science at schools. There is a gap between research and practice to connect curricular innovation with teaching practice; it is not restricted only to history and philosophy of science (see, among others, Pekarek et al. 1996; Pena and Ribeiro Filho 2008; Höttecke and Silva 2011). Thus, working collaboratively with in-service teachers is essential. In order to foster the use of history and philosophy of science in science education, it is important to take the teachers' perspective into account; otherwise curricular innovations will be hard to implement.

The introduction of disciplines in teachers training courses that combine scientific content and historical and philosophical issues with didactical aspects is highly desirable. It can allow future teachers to develop some of the needed skills to implement this approach in practice and to develop an awareness of the real worth of the use of history and philosophy of science in their teaching (Höttecke and Silva 2011).

It is also important to establish stronger cooperation between scholars in this field: one swallow does not make a summer. Collaboration may occur at several different levels. The creation of a national society for history and philosophy of science in science education, together with a specific journal and periodic meetings, might enhance the visibility of the area and provide a better forum for debate of researches and for the planning of national strategies. This does not mean that researchers working in this area should keep apart from other societies, of course. The creation of national databases for dissertation, theses, electronic versions of books, conference proceedings, and papers would be a nice instrument both for the improvement of research and for the dissemination of works. A teamwork including many groups and institutions could propose and lead ambitious projects – both research projects and educational ones. In a lower scale, a researcher producing new educational materials should ask the help of other researchers, from different institutions, to test and comment on his/her work; a researcher doing a survey of concepts on the nature of science at one institution should ask the cooperation of colleagues from other institutions to do a similar survey at other places, to compare their results. Researchers should think great: could my current work improve if I asked other people to collaborate?

Another front to be developed is a combination of research and application. We mean *real* application, such as posting on the Internet educational materials, together with suggestions for their use and additional materials (such as a video uploaded to *YouTube*). Of course, quality should always be a concern – both in research and application. A careful transposition can produce high-quality popularization and educational materials. The combination of those last two attitudes – trying to cooperate and to be useful in a broader sense – could greatly improve the situation in the area.

Roberto Andrade de Martins is currently a Visiting Professor at the Physics Department, State University of Paraíba, Brazil. His first degree was in physics (University of São Paulo) and his Ph.D. in logic and philosophy of science (State University of Campinas). He did postdoctoral researches in Oxford and Cambridge. His main research areas are history and philosophy of science (especially of physics and biology) and their use in science education. He was President of the Brazilian Society for History of Science (SBHC) and of the South Cone Association for Philosophy and History of Science (AFHIC). His publications include the following books: *Commentariolus: Pequeno Comentário de Nicolau Copérnico Sobre Suas Próprias Hipóteses Acerca dos Movimentos Celestes* (1990; 2003), *O Universo: Teorias Sobre Sua Origem e Evolução* (1994; 2012), *Contágio: História da Prevenção das Coenças Transmissíveis* (1997), *Os "Raios N" de René Blondlot: Uma Anomalia na História da Física* (2007), *Teoria da Relatividade Especial* (2008; 2012), and *Becquerel e a Descoberta da Radioatividade: Uma Análise Crítica* (2012).

Cibelle Celestino Silva is a Professor at the Institute of Physics of São Carlos, University of São Paulo, Brazil. She earned her M.Sc. and Ph.D. degrees on history of physics at the State University of Campinas and was a Dibner Fellow at Dibner Library in Washington DC, USA. Her main research interests are history of optics and electromagnetic theory. She is also concerned with physics teacher education, chiefly on bridging history and philosophy of science to classrooms and on nonformal science education. She is currently the head of the Group of History, Theory, and Science Teaching (GHTC), University of São Paulo. She is currently a member of the governing bodies of the South Cone Association for Philosophy and History of Science (AFHIC) and of the International History, Philosophy and Science Teaching Group (IHPST). One of the books she published is *Estudos de História e Filosofia das Ciências: Subsídios para Aplicação no Ensino* (2006).

Maria Elice Brzezinski Prestes is a Professor at the Department of Genetics and Evolutionary Biology, Bioscience Institute, University of São Paulo, Brazil. She achieved her first degree in Biological Sciences at Pontifícia Universidade Católica do Paraná (1982), M.Sc. in Environmental Sciences at University of São Paulo (1997), and Ph.D. in Education at the same university (2003). She did postdoctoral researches in Paris and Montreal. She has a wide experience in history of science, doing research on the following subjects: history of biology with emphasis in the eighteenth century and the uses of history of science in the teaching of biology. Her publications include the following books: *A Teoria Celular: De Hooke a Schwann* (1997) and *A Investigação da Natureza no Brasil Colônia* (2000) e *Florestas Brasileiras* (2003). She is currently the President of the Brazilian Association of Philosophy and History of Biology (ABFHiB) and editor of the journal *Filosofia e História da Biologia* (*Philosophy and History of Biology*).

Chapter 71
Science Teaching and Research in Argentina: The Contribution of History and Philosophy of Science

Irene Arriassecq and Alcira Rivarosa

71.1 Introduction

The analysis of the possible contributions to physics education made by the history and the philosophy of science constitutes a formidable task. Before we go on, a short note about some abbreviations that will be used throughout the text. From now on we will abbreviate the history of science as HS and the philosophy of science as PS; whenever we refer to both areas together, we will write HPS. In order to understand how complex this task is, we should first identify the multiple theoretical aspects that converge here.

On the one hand, physics as a scientific discipline has among its main objectives the aim of explaining, understanding and predicting natural phenomena. These objectives are achieved by intervening in those phenomena using specific methodologies and also specific language to communicate findings.

On the other hand, HPS, in spite of not strictly being considered a meta-science, is a hybrid field constituted by contributions from different meta-sciences, or second-order criteriology, which have other scientific disciplines as their objects of study (Losee 1972; Klimovsky 1994). HPS is a theoretical reflection of scientific knowledge and activity from an internalist and logical-linguistic perspective which focuses on the study of the processes, conditions and results of innovation, justification, systematization, application, evaluation and communication in science (Adúriz-Bravo et al. 2006).

M.R. Matthews (ed.), *International Handbook of Research in History, Philosophy and Science Teaching*, DOI 10.1007/978-94-007-7654-8_71,

More recently, a line of work under the name ‘nature of science’ has developed. It is made up of a group of meta-scientific laws which are valuable to natural science teaching, and it is precisely the ‘nature of science’ which constitutes its object of study.

The term ‘meta-science’ refers to all the disciplines which have science as their object of study: epistemology, history of science and sociology of science, among others. These disciplines provide different frameworks for the study of science, the aim of which is to answer questions such as ‘what are scientific knowledge and scientific activity like?’, ‘how does science change through time?’, ‘who have been the most relevant scientists in history and in what way are they relevant?’, ‘which are the values the scientific community adheres to?’ and ‘how does science relate to the other disciplines (humanities, technology, art) and other ways of interpreting the world (religion, myths, even popular beliefs)?’ (Aduriz-Bravo 2005).

Multiple contexts coincide in the area of science education: a discipline to be taught, theoretical frameworks, processes for teaching and learning, teaching proposals, teaching contexts, conceptions of such a discipline and its own nature on the part of both the teachers and the students, the teachers’ background, etc. Research into these aspects of HPS throughout its evolution has not always considered the possibility that the analysis of the topics of this subject could contribute to physics education. However, in recent years, this has started to be taken into account for the design of syllabuses, in light of the contributions made by researchers like Salomon (1988) and Lakin and Wellington (1994), who consider that the teacher’s view of science, whether explicit or not, affects what and how he/she teaches. In connection with this opinion, many other authors such as Lantz and Kass (1987), and Duschl (1997), state that a science teacher’s background should involve not only a science but also aspects related to the nature of science, such as knowledge about its purposes, methods and its relationship with technology and society.

In a time when scientific literacy has become one of the goals of science education in many countries, it is of paramount importance to gain a deeper understanding of the history and nature of science in order to achieve such an objective. It is expected that a scientifically literate individual should be able to distinguish between scientific and non-scientific knowledge, science and pseudoscience, to know the limits and scope of science as well as what science can or cannot explain and to identify the scientific methodologies. As an individual and as a member of a particular society, he should also be able to tell what is relevant to the scope of science, taking the positive as well as the negative aspects into account.

However, the concept of the nature of science (NOS), as Acevedo-Diaz and colleagues (2007) point out, is complex and dialectical and therefore difficult to define with accuracy and by general consent. Specialists often discuss descriptions and representations of the NOS which are as dynamic as scientific knowledge itself, and so it is impossible to support the idea of only NOS capable of representing either this knowledge or all the scientific disciplines. Therefore, any representation of the NOS will be partial and will compete with other incomplete representations.

With regard to science didactics, even though there is consensus about the importance of the NOS in science education (Bell et al. 2001), the means of achieving their own objectives are not clear.

There exist at present several international groups that study the applications of the NOS to science education at different levels. Among these groups one of the most important is the International History, Philosophy and Science Teaching Group (IHPST). This group has been holding conferences since 1989 and has encouraged international magazines with great prestige within the scientific community and among science education teachers – such as the *International Journal of Science Education*, among others – to dedicate special editions to the NOS and its relation to science education. Another major landmark was the creation of *Science & Education*: *Contributions from History, Philosophy and Sociology of Science and Mathematics*, which since 1992 has promoted the inclusion of history and philosophy of science and mathematics courses in science and mathematics teacher education programmes. Moreover, it promotes the discussion of the philosophy and the purpose of science and mathematics education and their place in, and contribution to, the intellectual and ethical development of individuals and cultures. It is associated with the International History, Philosophy and Science Teaching Group, and Michael Matthews is its editor.

The First IHPST Latin American Conference was held in 2010. This conference focused on the presentation and discussion of papers about the use of history and philosophy in science education, in accordance with the guidelines drawn up by the IHPST group for international conferences.

This chapter analyses the historical evolution of the HPS in connection with science teaching and learning, the different lines of research that have developed over time and some examples of teaching proposals – aimed at students, teachers and trainee science teachers – which were designed by taking research results into account. A critical analysis of the present situation regarding the incorporation of the HPS in science education is carried out, and some ideas are suggested in order to make progress in this direction. More precisely, the last two sections evaluate the situation in Argentina with regard to the incorporation of HPS contributions into physics and biology education. Some of the aspects analysed are the underlying epistemological features in educational laws and the natural science curriculum design at secondary level in Argentina, the incorporation of HPS into research and the dissemination of HPS contributions to physics teaching among in-service teachers.

71.2 Design, Implementation and Assessment of Teaching-Learning Sequences That Incorporate Contributions from the HPS

Teixeira and colleagues (2009), in a thorough and methodologically rigorous work, investigate teaching experiences of applying HPS in physics classrooms, with the aim of obtaining critical and reliable information on this subject.

The vast majority of the studies selected for analysis support the idea of similarity between students' spontaneous understanding of scientific concepts and the historical development of these concepts. The aim was to obtain a conceptual change, despite the large amount of criticism found in the literature about this type of approach. In spite of the presence of a variety of teaching strategies based on HPS, comparatively few of them provided the pedagogical references to justify the use of these strategies, and few were concerned with assessing the students' prior knowledge of HPS.

The studies analysed by the authors presented various ways of utilizing HPS in the teaching of physics: in relation to teaching objectives (learning concepts, nature of science (NOS), attitudes, argumentation and metacognition), in relation to teaching strategies (integrated with the subject of physics, integrated with another teaching strategy and not integrated) and in relation to didactic materials (historical narratives, biographies, replicas of historical experiments, historically contextualized problems and stories of scientists' lives).

The results revealed the occurrence of positive effects in the didactic use of HPS in the learning of physics concepts, despite there being no consensus about this, and they also indicated a lack of agreement about the occurrence of conceptual change. Greater research efforts are therefore needed to investigate these aspects, especially when the aforementioned limitations in research procedures are taken into account. In the same way, no consensus was found as to how HPS promotes improvements in the students' attitudes to science, which also leads the authors to conclude that this subject needs further investigation.

This type of approach appears to promote a more mature vision in respect of the students' understanding of NOS, which should be taken into consideration when planning curricula and/or physics teaching strategies. Favourable results were also found when looking at the effects of the didactic employment of HPS on the areas of argumentation and metacognition, despite the dearth of studies in the analysis dealing with these areas. Potentially important areas are being explored which warrant a higher position on the HPS-based physics teaching research agenda.

A recent thesis (Arriassecq 2008) dealt with the problem of meaningful teaching of the special relativity theory (SRT) at secondary school level in Argentina. Several studies have been carried out, focusing on the epistemological difficulties presented by the content of the SRT itself, the teachers' difficulty in approaching the task of dealing with such a theory at that level and the textbooks that both teachers and students would have as a teaching resource. The results of such studies showed that there is a wide gap between the proposals presented in the documents from the ministry, as well as some research reports, and their actual practice in class. In order to narrow this gap, a teaching proposal was developed in which the SRT is approached within a historic and epistemological context.

Part of the design of this teaching proposal – designed within a framework that comprises epistemological, psychological and didactic aspects – consisted of producing written material (in textbook format) to be used by teachers and students, taking into account the deficiencies identified through this approach.

Several studies conducted before the design of the teaching proposal and the supplementary teaching material for its implementation adopted an approach that assigns the use of the history of science and epistemology for the design of concrete class proposals, a role as important as that of working within a psychological and didactic framework. This contextualized approach places great conceptual emphasis on the topics discussed, so that the historical-epistemological discussions can be meaningful to students.

The use of the history of science and epistemology is considered to allow, among other aspects, the determination of the epistemological obstacles that serve as a guide for the selection of the relevant content to be taught as well as to favour the discussion of the production of scientific knowledge, the role of the social and cultural context at the time in which that knowledge is developed and its impact within and outside the scope of science. The aim should be to eradicate stereotypes about science that keep students away from this discipline.

With regard to the epistemological aspect, the thesis draws on elements of Bachelard's epistemology (1991) to produce an epistemological analysis of the content of the SRT (Arriassecq and Greca 2010). This analysis defined the central concepts that students should learn in a meaningful way. These are space, time and notions related to reference systems, observer, simultaneity and measurement, which are essential for a relativistic understanding of space-time.

The results of the assessment of the implementation of the teaching proposal show that the acquisition of key concepts of the SRT seems to be much better than those obtained when the SRT is approached in a 'traditional' way, in which the traditional textbook is the main teaching resource used by the teacher (Arriassecq 2008; Arriassecq and Greca 2010).

As for the text produced as part of the design of the teaching proposal, it treats in greater depth a topic that, despite its importance, has not been sufficiently investigated within the area of physics education in Argentina. In addition, it has been produced within an innovative theoretical framework that comprises epistemological, psychological and didactic elements.

71.3 Researches on HPST in Latin America

In Latin America, Brazil was the first country to consolidate the science education area and then to incorporate the study of the contributions made by HPS as a line of research within science education itself. Researchers in the science education area in Argentina have been establishing links with researchers in Brazil since this area started developing in this country. This has been done on the one hand through the guidance given to Argentinean researchers on their theses by prestigious Brazilian researchers such as Marco Antonio Moreira, from UFRGS. On the other hand, it has been accomplished by Argentinean researchers spending time at Brazilian institutes and universities as well as by disseminating and publishing Argentinean research projects in pioneering magazines issued in Brazil.

As Villani and colleagues (2010) point out in a thorough review, the development of science education research in Brazil was very similar to that which took place in many other Western countries, at least until the early 1990s. Research in science education first appeared systematically 40 years ago, as a consequence of an overall renovation of the field of science education. This evolution was also related to the political events taking place in the country.

After this period, Brazilian researchers became less dependent on foreign sources, and original lines of research were introduced, differentiating the development of this period from the one preceding it. Finally, the role of the history and philosophy of science appeared as an important intermediary during the stabilization process, not only unifying a great number of the research projects carried out during that period, but also serving as a means of participating in the political and ideological arena.

During the first phase, which included the founding of the area, the history and philosophy of science played only a limited role in the process of institutionalizing science education research. On the one hand, articles and books showed thinking based on the simplistic idea that the mere knowledge of the history of science would in itself stimulate students' motivation and facilitate their learning of scientific concepts. Other books and articles seemed unrelated to teaching and showed very little progress in exploring the history and philosophy of science more efficiently in the classroom. However, the community of researchers involved in educational projects considered that contributions from the history of science were very important, including its practical results, such as the production of teaching material to complement projects for physics teaching.

During the 1970s, some of the researchers went on to study further and publish a history of science that included the connections and commitments between scientific development and economic and political power. This task was considered a way to combat the military dictatorship then in power in Brazil and thus implicitly to denounce the pact between universities and the government.

The contribution of the history and philosophy of science to the consolidation of the area was stronger during the 1980s. First, journals founded during this period disseminated their ideas to others who were also interested in the history and philosophy of science. The *Journal of Physics Teaching* was launched in 1979, but until 1993 it had no specific section dedicated exclusively to the history and philosophy of science. Nonetheless, each edition contained individual articles dedicated to the theme. In contrast, right from its beginnings in 1984, the *Santa Catarina Journal of Physics Teaching*[1] included a section entitled 'The History and Philosophy of Physics'.

Another important contribution came from abroad, where the students could develop studies about the history and philosophy of science.

During the 1990s, a more theoretical contribution of the philosophy of science also fostered the development of variations in the Conceptual Change Model, giving special emphasis to other philosophers besides Kuhn and Lakatos. Specifically, some researchers developed analogies between science learning in school and the development of science as understood by Feyerabend, Laudan, Popper and Bachelard. Villani (1992) explored the flexibility of Laudan's approaches to the progress of science

---

[1] *Revista Catarinense de Ensino de Física.*

(Laudan 1984) for understanding the changes that take place in students' ideas in school. Based on Bachelard's idea of 'epistemological profile' (Bachelard 1978), Mortimer (1995) proposed a new version of the same concept, which became known as conceptual profile. He posited that cognitive evolution intrinsically joins old ideas with new ones and considered that teaching should promote a change in students' profiles by broadening their spectra of useful ideas.

During the last phase of the institutionalization process of science education research, two trends were developed in relation to the history and philosophy of science: towards reforming the cultural scientific knowledge on which high school education was based and towards training teachers to develop corresponding lines of research.

The first trend was a reform in scientific knowledge, focused on information concerning the genesis of conflicts and the evolution of scientific theories as well as on successes and failures. The work was carried out at schools themselves. But time should also be devoted to reflection on the presuppositions, images and basic intuitions of scientific advances. The training of science teachers should foster the acquisition of this knowledge for two purposes: first, from the cultural standpoint, to enrich the quality of the content to be taught and, second, to adhere to the methodological requirements that were considered the most appropriate.

In the second trend, researchers in the history and philosophy of science comprised a specific group, with their own graduate and postgraduate courses, journals and congresses.

The researchers' work became more technical (Martins 2000; Pietrocola 1992), their methodology became more precise, and case studies were included, such as information about Becquerel (Martins 1997) and the alchemist Sendivogius (Porto 2001). At the same time, efforts were made to keep in contact with the area of science teaching through attention to studies such as Newton's theory of colours, which is full of technicalities but useful for teaching purposes (Martins and Silva 2001).

In the case of Argentina, as Orlando and colleagues (2008) point out, the physics teachers' community received great encouragement in the 1980s. More precisely in 1983 in Cordoba, the physics education meeting (REF),[2] which attracts more than a thousand teachers of this subject matter, was held for the first time in several years. At that meeting the Association of Physics Teachers of Argentina (APFA)[3] was created. This association would be in charge, among other things, of organizing periodical meetings and events. The success of such events was reflected not only in the number of people present and the variety of topics that were discussed but also in the increasing number of research projects presented. Throughout the years the increasing number of research papers that were presented in that meeting showed the need for the creation of another meeting focused on research on the area. This new meeting was called the 'Symposium on Physics Education Research' (SIEF), and the first one took place in Tucumán in 1992.

---

[2] Reunión de Educación en Física.

[3] Asociación de Profesores de Física de la Argentina.

APFA is responsible for summoning researchers to an alternate REF and a SIEF every 2 years. The researchers' community has been growing in number and its tasks have become more specific. At the beginning the number of researchers with a doctoral degree was small, and this was done either abroad or under the guidance of foreign supervisors. Nowadays it is possible to form human resources and take postgraduate courses in our country.

The growing number of projects presented at the various symposiums throughout the years would reflect the researchers' increasing interest in working on topics related to physics education in the different education areas.

The increase in the number of articles that follow those criteria for research work since the first SIEF up to the present shows growth in the construction of knowledge in the field of physics education as well as an incremental change in specific training for researchers in science education.

It should be noted that the research projects presented at the symposiums deal with heterogeneous topics. Most of them refer to problems connected with teaching, learning, curricular aspects and context problems or about the teacher training or with educational transfer. A small percentage of them deal with topics related to theoretical frameworks, epistemological aspects or methodological development. However, there has been an evolution in research related to the use of HPS as a theoretical framework. This will be addressed further.

There are still some questions to be answered: Have the curricula – especially secondary school curricula – included HPS? Do the curricula of colleges of education provide for training in HPS? What happens with practicing teachers who as undergraduates did not have the chance to become familiar with the contributions made by the HPS to science education? Do class textbooks, both the teachers' and the students', incorporate such contributions? If they do, how do they do so? Are there any teaching proposals based on research results?

The next section evaluates HPS contributions to science education in Argentina. Some of the aspects analysed are the underlying epistemological features in education laws and natural science curriculum design at secondary level in Argentina, the incorporation of HPS in research and the dissemination of HPS contributions to physics teaching among in-service teachers.

71.4 Incorporation of Contributions from the HPS into Physics Education in Argentina

This section evaluates the incorporation of HPS into physics education in Argentina. The analysis focuses on education laws and on curriculum designs – particularly at secondary level – on the most relevant aspects of the curriculum designs for physics teacher training and on research and articles published in *Physics Teaching Magazine*, which is a publication issued by the Association of Physics Teachers of Argentina (APFA).

The selection of the materials analysed was based on the fact that the APFA magazine is the main channel of communication between researchers and teachers.

It should be noted that most of the researchers who attend national events and publish in the aforementioned magazine also attend international events and publish in prestigious magazines in other countries. However, only a small number of teachers have access to them.

71.4.1 Epistemological Features Underlying Educational Laws and Curricular Designs for Natural Science Teaching at Secondary Level in Argentina

This section analyses several national education laws that have been, and are still, enforced in Argentina, the regulations on some of these laws which provided a frame of reference at certain times in Argentinean history and in curriculum designs – for natural sciences at secondary level. Curriculum designs were formulated by the Ministry of Education and the Buenos Aires Provincial Ministry of Education in order to define possible epistemological conceptions in the history of Argentinean education, based on the stances underlying, sometimes implicitly, the aforementioned ministry documents (Framework for the Oriented Bachelor in Natural Sciences 2011).[4] This province was chosen because it accounts for 33 % of all the educational institutions of the country and accounts for 38 % of students.

Society has changed throughout the history of the country, from an economic, as well as a political and a cultural, point of view. Education policies are therefore expected to evolve and create favourable conditions for teachers, students and institutions so that objectives are achieved, adjusting to changes in society.

Particular consideration is given to whether there has been an evolution in the epistemological criteria that promote certain models for natural science teaching at secondary level and the development of notions, not only about science but also regarding scientific activity in different types of secondary schools. Furthermore, the aim is to identify certain characteristics present in the evolution of educational laws and in curriculum designs that may indicate an evolution from the so-called standard epistemologies to nonstandard ones.

The descriptive analysis is based on the identification of the characteristics of standard and nonstandard epistemologies in the following documents:

– The four national education laws: Law 1420 dating from 1884, Law 4874 from 1905, Law 24195 from 1993 and Law 26206 from 2006. Each was duly ratified and promulgated at a different time in Argentinean history, which means that each was conceived within different social, economic, political and cultural contexts. Only in the last two laws are there explicit references to epistemological debates.

---

[4] Marcos de Referencia. Educación Secundaria Orientada. Bachiller en Ciencias Naturales. Aprobado por Res. CFE N° 142/11. Consejo federal de Educación.

- Two magazines: *Annals of Education of Buenos Aires Province* and *of Santiago del Estero Province*. Since, in the past, curriculum designs were not developed, State guidelines on teaching practice are only found in this kind of magazine on education.
- National and Buenos Aires Province curriculum designs for natural sciences. This province was chosen because it includes 33 % of the educational institutions in the country and 38 % of the students.

The analysis focuses especially on education laws and the corresponding curriculum designs at the secondary level.

Law 24195, dating from 1993, sets the guidelines for the national educational policy under the so-called Education Federal Law (EFL) and determines the structure of the educational system as consisting of early education; basic general education; the 'polymodal' level, with final (preuniversity) oriented cycles, among which is the natural science-oriented one; and higher and postgraduate education. The objectives of each of these levels are also defined in the different articles of the official curricular document. The regulatory style of the previous laws was abandoned in order to extend compulsory education to 10 years.

With regard to teachers, their rights and duties are established in Art. 46 and 47 of the EFL. The pedagogical and curricular guidelines mention academic freedom and freedom of education.

This law is accompanied by a national curriculum design, and each province develops its own with the different polymodal orientations.

In the document entitled 'Curricular Support Document N°1' (Petrucci 1994), about the natural sciences area – in particular, physics curriculum design in Buenos Aires Province – the author states that the document '… is a useful theoretical support when planning, implementing and assessing teaching practice …'. Teaching is considered a professional practice in which theoretical foundations underlie decisions, and therefore there are neither recipes nor methods to implement the teaching-learning process.

The view of science expressed here contradicts the traditional one which considers that science uses a unique method consisting of a 'recipe': several steps to obtain a product. Science is regarded as '… an open process, the stages of which are determined by the issues under study, the aims of the study, the historical context and the interests of the community'. As regards the way in which research work should be presented, the document states that '… according to present epistemological conceptions, scientific knowledge is built through a process of development of theories and models that aim to give meaning to a reference experimental field'.

In addition, the document recommends some authors who, based on the present theoretical framework for science teaching, stress the dynamic and provisional character of scientific knowledge, highlighting therefore its dependence on the historical context (Kuhn 1962).

The latest law, the National Education Law, sanctioned in 2006, modifies the organization and selection of the curriculum contents of the national education system. Four levels of education were established, early, primary, secondary and upper secondary/higher, whereas the period of compulsory education was increased to 13 years.

The national curricular design corresponding to this law refers to that regarding the natural sciences orientation within upper-secondary level. In the introduction, teachers are asked to present science '… as a social construction that is part of culture, with its own history, communities, agreements and contradictions …', to treat models and scientific theories as attempts to answer real problems and to take into account the role specific teaching methodologies play in understanding teaching-learning processes.

One of the general objectives is to form scientifically literate citizens who, during their school years, develop both scientific knowledge and a view on scientific activity.

In present designs, HPS takes on a different status, as the core thematic contents include science history and philosophy in order to approach the subject within its own curricular area at secondary level.

To sum up, the epistemological characteristics underlying educational laws and documents regarding natural science teaching at secondary level in Argentina have evolved since the first laws were sanctioned. They have developed from a teaching approach with positivist characteristics to models underlaid by nonstandard epistemological conception.

This evolution of the view on science promotes at the same time a change in the science teaching and learning approach, offering new roles for teachers and students, from a model in which the student is 'recipient' of knowledge 'imparted' by the teacher to one in which the student 'builds' 'academic knowledge' through the teacher's mediation.

71.4.2 The Incorporation of the HPS in Teacher Training

The general guidelines that physics teachers follow to learn topics of epistemology are derived from the regulations laid down by the organs responsible for education policies at the different levels of education in Argentina. In her thesis, Islas (2010) compiles all the documents that give advice on the incorporation of the HPS into the syllabuses of physics teacher training colleges.

The document '2008-Science education year' extracts the main points of the Report of the Argentinean National Commission for Improvement in Natural Science and Mathematics Education. The report stresses

> the need to overcome both the simplistic views on science and scientific work as well as those views of scientific work as something extremely difficult which lead to school failure. […] At the same time the program aims at arousing interest in those disciplines that follow from understanding what producing science and producing mathematics mean, their usefulness and importance for citizenship; at demystifying the process of knowledge development for students and teachers at different education levels, encouraging them to value it as an activity for social construction; at promoting future scientific vocations.

In the recommendations section of the document, those objectives are translated into some suggestions that are transferable to teaching practice. It is recommended that the different aspects of scientific knowledge should be taken into account, some of which are 'its empiricism, the need to build models, compulsory debate and discussion of the results and their interpretations'.

There are other points in the document regarding classroom work, of which it is worth mentioning the following one:

> Generally, in order for the students to build solid knowledge there should be experimentation, high frequency of questions, socratic dialogue, and rigorous, logically sound and simple reasoning. All these are characteristics of "proper thinking" in the science class. But they are also distinctive characteristics of scientists' thought when doing research.

Some lines below, in order to differentiate the contexts where knowledge is developed (the class and the researchers' community), it is stated that 'the most significant difference between both activities is that, whereas the scientific community generates new knowledge on the borderline between the known and the unknown, students in class build concepts that, despite being new to them, have already been validated by science'. Finally, it is worth pointing out that the Report of the Argentinean National Commission for Improvement in Natural Science and Mathematics Education states that one of the obstacles that have been detected in the diagnostic is the 'stereotyped picture of science and scientists, also shared by teachers'.

Most of the professors who are members of universities or state institutes have some curricular time at their disposal to study topics related to the HPS. Moreover, all courses include time for seminars in which it would be possible to approach topics connected with the construction of scientific knowledge.

Islas (*op. cit.*) has also done a review of the syllabuses, taking into account, apart from the list of contents, other elements such as the bibliography, the objectives of the subject and the requirements for passing the subject.

A characteristic that all programmes under analysis have is that they include nonstandard epistemologies. Even more, the section entitled 'tendencies among contemporary epistemologies', which appears in almost all syllabuses, is considered an indicator of the presence of innovating explanations. Authors like Kitcher, Giere, van Fraassen, Habermas and Gadamer appear in the references together with the more common ones like Lakatos, Feyerabend, Laudan, Toulmin and, to a lesser extent, Bachelard.

71.4.3 The Communication Among In-Service Teachers with Regard to HPS Contributions to Physics Teaching

The magazine *Physics Teaching,*[5] first published in 1985, is an undisputed reference on this issue at every level and is also a vehicle for communication among the members of the Association of Physics Teachers of Argentina.

---

[5] *Revista de Enseñanza de la Física.*

The magazine has been published twice a year since 1992, and there are some special issues, with research articles, proposals for the classroom, reflections, notes and information on different aspects related to physics and physics teaching. It makes possible the communication of research works in the area of science education, providing insight into theoretical foundations, analysing the state of the art and making headway in understanding significant issues. It provides elements to enhance teaching practice, allowing the publication of teaching proposals, discussion of particular activities and analysis of experiences. It promotes events of interest, and it offers information and news that help members of APFA, as well as any readers, to keep up to date.

Three publishing teams have been in charge of the magazine during its 27 years of existence. The first one was in charge from 1985 to 1992, the second from 1993 to 2002 and the present one from 2003. The same spirit has been present in all of them, and it is possible to find articles that match the objectives mentioned above. However, the organization of the magazine has gone through different changes.

The first issues did not have permanent sections. During the second publishing period, the following sections were introduced: research and development, teaching issues, physics topics, history, science philosophy, information and news. Not all these sections were present in every issue and were replaced by others such as laboratory work and extracurricular activities.

The magazine now has permanent sections in all the issues. Each section is briefly discussed below so as to analyse those that deal with HPS contributions.

The 'Research' section includes articles on education research, related to teaching and learning of physics and other experimental sciences in general. It covers the incorporation of empirical research that answers paradigms and diverse approaches, as long as this is carried out with scientific rigour and systematicity, the development of theoretical frameworks, advances in methodology or revisions that deal with the state of the art on topics regarding research in science education. The 'Proposals' section includes articles offering teaching alternatives, innovations and curriculum formulation, among other topics, in connection with the teaching of physics and other experimental sciences at different levels. It may include contributions made in order to integrate physics with other sciences, specific classroom proposals and analysis of the curriculum and of resources. In the 'Essays' section special thematic articles are published (articles on physics topics, on the science-technology-society-environment relationship, philosophical and epistemological reflections, historical accounts, description of projects or programmes, etc). The 'Miscellaneous' section deals with discussions of problems, challenges and paradoxes, comments on books and/or software, teaching materials on the web, projects, classroom resources, etc. Finally, the 'News' section includes information on events and news of interest, workshops, development and information about postgraduate level courses, thesis abstracts and book reviews.

In the second period of the magazine, two types of articles coexist in the 'History' and 'Science Philosophy' sections. On the one hand, there are those that have been written by teachers and physics researchers who have taught or done research in this subject at different levels of education. Even though they lack a formal education in history and epistemology, they have been in a way pioneers in the incorporation of such debates in teaching. The first issue in 1997 featured an article in this respect written by Dr. Alberto P. Maiztegui – for many years president of the National Academy of Sciences and without any doubt remembered for his contributions to science teaching: his physics books for students and teachers, the promotion of science fairs in Argentina and the steady support to these topics that he provided from IMAF (nowadays FaMAF) and later the National Academy of Sciences. The article was entitled 'Archimedes and Hieron's crown' and was based on the well-known anecdote that describes Archimedes running naked around the streets of Syracuse exclaiming '¡Eureka! … ¡Eureka!' because of the joy he felt when finding a solution to the scientific problem he was working on. The article develops a series of detailed calculations, in connection with the problem in question, which are not frequently found in secondary textbooks. It should be noted that the article cites a source where the anecdote can be read, contrary to other texts that try to incorporate 'historical cartoons', without any mention of sources, only because students may find them attractive.

In the same issue, Guillermo Boido published the article 'The reconstruction of experiments in the history of science: Galileo under discussion' which states that the reconstruction of experiments carried out by scientists in the past has contributed to a better understanding of certain historical episodes and that this method has gained popularity especially when applied to Galileo's work, even though the results have received controversial interpretations. The possibilities and limitations of experimental history are explored, and there is a brief analysis of the state of the discussion – at the end of the 1990s – on the character of Galilean science in light of the reconstruction of some of his experiments. Prof. Boido does research into epistemology and science history and has been associate editor of the prestigious Argentinean scientific magazine *Science Today.*[6] The professional profile of this author is clearly different from that of the author of the article mentioned above. This article focuses on science history research problems. At the same time, the editors point out that the article

> … is valuable material for our readers, particularly now that science history demands attention on the part of science education and a better place in the curricula in general, both at secondary and higher education levels.

Finally, in the present stage of the magazine, there has been a significant change with regard to the kinds of publications that consider the incorporation of HPS contributions to science and particularly to physics education. They share in common the fact that they are research articles written by researchers who have been specifically trained in science teaching. This means that they are not historians or philosophers making contributions from their own disciplines or physicists exploring history and philosophy topics. They are physics teachers and physics teaching researchers who, based on a solid background as regards the nature of science,

---

[6] *Revista Ciencia Hoy.*

identify problems in physics teaching and learning and deal with them from a historically and epistemologically contextualized approach.

The following are examples of articles of such a kind (all of which were published in the 'Research' section, except one that appeared in the 'Thesis' section):

'Teachers' conceptions of the role of scientific models in physics classes' (Islas and Pesa 2004)
'The Scientific Revolution in the Argentinean Education System' (Cornejo 2005)
'Analysis of relevant aspects to deal with the Special Relativity Theory in the last years of secondary school from a historically and epistemologically contextualized approach. First part 1 and 2' (Arriassecq and Greca 2005)
'Laboratory work design within an epistemological and cognitive framework: Physics Teacher Training College case' (Andrés Zuñeda 2006-doctoral thesis-)
'Mechanics teaching at secondary school: historical evolution of the texts (1840–2000)' (Cornejo and Nuñez 2006)
'The view of a group of science teachers on science and schooling' (de la Fuente et al. 2006)
'Teaching the philosophical components and the different views on the world of science: some considerations' (Matthews 2009)
'Epistemology for physics teaching training courses: transpositive operations and the creation of a 'metascientific school activity'' (Adúriz-Bravo 2011)

71.4.4 *The Incorporation of Contributions Made by the HPS into Argentinean Textbooks*

There is research that studies how to incorporate the HPS into the physics textbooks used by both teachers and students. Arriassecq and Stipcich (2000) follow this line of scientific enquiry. Their work offers a critical analysis of the incorporation of the HPS into physics secondary textbooks that were written after the educational reform that took place in Argentina in 1993. One of the main conclusions these authors point out is that the HPS is not incorporated into school textbooks within a theoretical framework but it is rather reduced to mere anecdotal vignettes or, at best, to the inclusion of a chapter on epistemological aspects which do not bear any relationship with the rest of the text structure and approach. They also draw attention to the need to incorporate concrete proposals to deal with the contents of the HPS in class.

In later studies (Arriassecq and Greca 2004, 2007), it is argued that the results of different investigations point out that:

- The textbook appears to be the main resource that teachers use for preparing their classes, especially at secondary level. The same textbooks are recommended to students.
- The way in which topics are approached may seriously condition the results achieved by students when learning them.

In the same studies, which refer specifically to the treatment textbooks give to the special relativity theory (SRT), it is argued that the teachers who face the task of approaching the SRT for the first time will generally resort to the textbooks as a guide for their classes. Considering that in many cases the teacher has not had the opportunity to reflect on which concepts are the most relevant to understand the theory, he will probably follow the plan offered by the textbook or several textbooks he has selected to prepare his class, without adapting the material to fit his own criteria.

On the other hand, the results presented in this article coincide with those obtained on the same topic in other countries. This demonstrates that in order for secondary teachers to approach topics, such as the SRT in this case, from an epistemological and contextualized perspective, the available teaching materials are inefficient.

Based on that fact, it seems necessary to produce teaching material to be used by teachers and students, which provides for students' meaningful learning by introducing contents appropriately from a conceptual and motivational point of view.

This material could offer a serious discussion based on the contributions made by research into physics education, about the contextual aspects that are relevant to several physics theories.

Kragh's contextualized, or 'anti-Whig', approach analyses historical events in light of the beliefs, theories and methods that belong to the time when the ideas were conceived. This view offers a more realistic idea of history that does not fail to take into account obstacles and mistakes in scientific work. This view of science that textbooks may therefore reflect would be more realistic since it would give the same importance to successes as to failures.

71.5 Incorporation of HPS into Biology Education in Argentina

This section evaluates the incorporation of HPS into biology education in Argentina. The analysis focuses on the most relevant aspects of the curriculum for biology teacher training and research and the dissemination articles published in *Biologics Teaching Magazine*, which is a publication that has been issued by the *Argentinean Biologics Teachers Association* (ADBiA) for the last 15 years.

HPS has been incorporated into biological sciences and their teaching, both in the curriculum and in teacher training colleges, on the basis of complementary lines of development. On the one hand, there has been an advance and an epistemological turn in the development of knowledge in biology in the twentieth century (the molecular revolution, genetics and biotechnology, ecosystemic studies regarding human production, economy and consumption). On the other hand, the global/local crisis in scientific education has given birth to a second line that questions the science curricula, and a third line refers to science teaching in search of identity as a field of education research.

71.5.1 Evolution and Changes in Biology

Biology studies life and its organization in unifying principles of different levels of complexity: biosphere, ecosystem, population, individual, organism, organs, tissues, cells, macromolecules and biochemical level (biodiversity, taxonomy, Mendelian and population genetics, embryology, biology of the organism, molecular biology).

It is a mainly historical and evolutionary science, which develops explanatory models based on different research methods – comparative, systemic, hypothetical-deductive, genetic and historical ones – within structural, functional and behaviourist approaches (Ruiz and Ayala 1998; Barberá and Sendra 2011).

The conceptual and methodological development of biology differs from the research paradigm for physics, since life processes – self-regulation, unstable equilibrium and invariant and irreversible evolution – are informed by diachronic and synchronic perspectives, articulating internal and external interactions in an open system. On the other hand, its explanatory models are connected with various social and human practices (Giordan 1997; García 2006).

Advances resulting from technological research and applications to improve the quality of life, such as the digitalization of the genetic code and its molecular delimitation, led to numerous developments in biochemistry, medicine, technology and science. These, in turn, brought new and complex ethical problems with an economic and social impact (transplants, medicines, biochemical weapons, food production and biotechnology) (Testart and Godin 2002; Geymonat 2002).

With that in mind, and as a result of the multiple ethical conflicts, studies have been promoting new research and educational directions that combine new approaches (environmental, STSE, humanistic ones) with the bioecological, social, economic and political dimensions (Gudynas 2002; Sacks 1996). As a result, different areas of knowledge have produced proposals of an interdisciplinary nature linking science, cultural practices and the natural and social environment, as is the case for health and environmental education.

Biological knowledge in textbooks and curricula was not greatly updated until 15 years ago when the popular communication of the issues offered an opportunity to revise knowledge in interaction with health, economy, agricultural production, food and medicine industries, etc. (Datri 2006; Memorias ADBia 1993–2000).

71.5.2 Scientific Education Crisis

The international education movement following this line (Fourez 1997; Jenkins and Pell 2006; Hodson 2003), as well as the dissemination of magazines dealing with science education during the last 40 years, is evidence of the ideological turn which took place from the 1970s, affecting the objectives of scientific training. Some of them that centred on the development of theories and concepts pertaining only to the discipline were gradually modified by the incorporation of new objectives and strategies – the scientist's doings; the question of method and disciplines; and the incorporation of history, the sociocultural context of science and the ideological, economic and ethical assumptions (Latour and Woolgar 1995; Matthews 1991, 2009).

The science teacher associations, the AAAS and the NSTA (National Science Teachers Association, USA), have been contributing with their harsh criticism since the 1970s: they recommended in their documents of the years 1979 and 1986 that students should be given the chance to explore the history and the philosophy of science. In other words, students should reach basic understanding of how sciences and technologies were developed in the context of humanity. The long-standing recommendations and projects for the incorporation of HPS into science education constitute a tradition that dates back to the mid-nineteenth century (Paul Tannery, Pierre Duhem, Ernst Mach), the analysis of the historical cases of Harvard's project (Conant, James) or the British Nuffield project (Duschl 1995; Datri 2006; Martínez and Olivé 1997).

Therefore, the so-called science for all takes up the 1960s and 1980s challenge (Secondary Curriculum Review 1983 Great Britain; Learning in Science in New Zealand) to try to cover educational deficiencies that are the consequences of a scientific and cultural heritage from the mid-century: the break with the certainties of scientific progress and the manipulation of its intellectual product (Fensham 2002; Ramontet 1997). Such contributions lead to educational proposals based on three lines: 'Science in society', 'Science in a social context' and 'Science and Technology in Society', developing a range of topics that give rise to teaching booklets on scientific work: the role of government and industry in science, the commercialization of scientific breakthroughs, the involvement of researchers in food production, the fight against disease, nuclear weapons, technology in everyday life, etc.

These events interact with an educational crisis in biology teaching at school level which establishes the need for science for all, from the point of view of its role in society rather than science itself, thus adding weight to the arguments that claim that the curricula present a very limited vision of science, without any historical and cultural contextualization or any reference to its social impact. This approach aims to motivate the student not only to study scientific disciplines but also to view themselves as citizens and to be able to take a stand on the value and the use of scientific knowledge.

It is in this spirit that the *Argentinean Biologics Teachers Association* (ADBIa 1993) began active participation and played a crucial role in establishing and defining the epistemological scope of the contents set by the education reform in Argentina (1995, 1997) and in highlighting the need to include contextual, historical and ideological approaches in the biology curricula. After the return of democracy (1983), teachers' opinions on biology teaching became visible during the discussions within the framework of the curricular reforms, pointing out as weaknesses the dissociation between what is taught and real everyday problems, the encyclopedic approach, the atomization, the lack of the history of ideas and cross-cutting topics (ADBia 2002). In this respect, secondary teachers are the ones who have made constant demands for the updating of the subject in line with the results of research in the field of biology (De Longhi and Ferreyra 2002).

In the 1990s, the Science, Technology, Society and Environment (STSE) approach pervaded biology educational programmes in different ways: (a) CTS[7] was incorporated into a year or course; (b) from *scientific problems to concepts* was taught from the CTS approach; and (c) the scientific content in CTS proposals had 'a subordinate role' (Marco Stiefel 2005). It should be noted that the STSE approach was expressed in the biology curricula through the teaching of environmental conflicts, facilitating a break with the traditional scientific content and introducing new strategies for understanding and dealing with the environmental conflict, the study of the social reality and a conscientious citizenship.

Concurrently with the contributions from the new philosophy of science, psychogenetic studies on biological notions (Giordan and De Vecchi 1987; Piaget and Garcìa 1982), in 1990 the ADBiA Journal presented an interesting alternative to explore the historical perspectives of the ideas and the socio-cognitive processes in students, in this way providing the educational debate with new epistemological criteria for establishing the curricular science contents. In this context, it therefore became essential to reintroduce the history of science and its conceptualization, especially the two characterizations regarding the nature of science, expressed as (a) science as a process of justification of knowledge (what we know) and (b) science as a process of discovery of knowledge (how we know).

In this regard, the first characterization has dominated the contemporary teaching of biological sciences, providing incomplete knowledge of its conceptual and axiological field. There is at present a need to broaden the science curriculum and to design and implement teaching proposals that deal with the other aspect, that is to say, 'how' the model for the transmission of hereditary traits or its evolutionary process became known (Wolovelsky 2008). This involves going beyond a simple historical account as the central theme of our classes to deal with philosophical views which serve as tools for analysis and meta-reflection, allowing a better understanding of the aspects of scientific practice and showing the different lines of argument in the context of technological and sociocultural breakdown (e.g. the spontaneous generation theory of the twelfth century, the fixism theory in the sixteenth century or the synthetic theory of evolution in the twentieth century). There are many beliefs and pseudosciences present in our culture, especially regarding topics like the origin, continuity and evolution of life, to which the historical and philosophical contextualization may significantly contribute by favouring less radicalized and less dogmatic positions (Schuster 1999; Palma & Wolovelsky 2001).

In this regard, we now know that the meta-scientific approach allows the establishment of relationships between the knowledge taught and its historical and evolutionary context, problematizing it within a cultural moment, with the strategies, ideas and problem-solving approaches available at that time. This meta-scientific component in the definition of science teaching practices on the

---

[7] Ciencia, Técnica y Sociedad.

one hand informs strategies for didactic transposition and, on the other, broadens the scope of traditional science teaching and learning models (Adúriz-Bravo et al. 2002b; Aduriz-Bravo 2005; Quintanilla et al. 2005).

Following from this, objectives have been set for the teaching of the biological sciences which relate to those skills students should develop:

- To learn the concepts within the context of the models and theories that created them. That is to say, bring the intention behind the phenomena closer to the models put forward by the scientific community. Such interpretation calls for the development of cognitive and scientific reasoning skills, usually referred to as 'doing sciences'.
- To promote conceptual change, practical and argumentative reasoning and understanding of the problematic, historical and cultural condition of scientific practice.
- To develop critical and projective thinking, which enables students to give opinions and take decisions. All of the aforementioned should provide for a non-neutral image of science under constant review, with technological applications and immersion in a sociocultural context.
- Promote, in turn, scientific literacy that provides basic culture and enables students to take decisions, analyse information, raise questions and detect deception.

71.5.3 The Identity of Teaching as a Research Area

On the one hand, the studies developed from the teaching of science provide an area of epistemological enquiry and revision of scientific knowledge, developing processes of transposition of communication and teaching hypotheses.

In this regard, the history and evolution of the major theories of the last 150 years confer identity to biology concerning not only its content and explanatory models but also the impact such knowledge causes, the attitudes it fosters and its relationship with different ways of life and culture (Memorias de las V Jornadas Nacionales de Enseñanza de la Biología). Instead of an academic practice, the teaching of science becomes therefore a learning process oriented to daily life, community, work and production activities.

There emerges the view that the student should acquire an idea of science connected with social issues, especially specific present ones. Among these, we can mention those related to the main pillars of development and sustainability, the management of natural resources, the oil and petrochemical industry, the mining industry and technologies, agriculture and agroindustries, metal mechanics, the food industry, the environment, health and biotechnology (Meira 2006).

Present societies are gradually becoming more and more dependent on technological knowledge, restating the relationship *production-information-education.* A new kind of citizen literacy is then suggested since the communication and appropriate significance of topics related to health, nutrition and pollution demand individuals who can be critical of problems and their solutions and able to improve the quality of life and their environment. In this direction, research into teaching has also proved that learning centred only around the incorporation of conceptual content fosters a distorted and limited view of scientific activity and its real production practices.

A wide range of research works agree on the fact that students gain a better conceptual understanding when they try to understand the origin and nature of knowledge, the argumentative conflicts and the sociology of research, as well as the ethical and attitudinal dilemmas among individuals and institutions (Jiménez and Sanmarti 1997; Lemke 2006; Rivarosa et al. 2011).

Moreover, the systematization of research into biology teaching at the national level (De Longhi et al. 2005; Berzal 2000; Astudillo et al. 2008) highlights the need for innovation in teaching practice based on issues related to (a) the history of biological notions and their epistemological development and the analysis of students' notions and conceptual obstacles and the problematic issues in connection with biology and culture, (b) the teacher's background and thinking and the transposition of communication and (c) the teaching models and the curricular materials.

It should be noted that the main concern in the last decade (2000–2012) has been mainly to promote curricular and training opportunities (postgraduate courses, master's degrees, seminars) for teachers to develop a real understanding of scientific activity and its relationship with genuine issues, to be used as a relevant criterion to rethink the teaching of biology. For this purpose, time should be devoted to education research into major biological notions, the analysis of documentary sources, biographical texts and historical events, the levels of curricular complexity as well as tracing back instances of scientific performance, all of which will help to question and change conceptions regarding biological theories and their teaching.

Furthermore, the bringing together of the meta-scientific knowledge (HPS) and the teacher's subject and teaching knowledge provides complementary options for problematizing themes. These allow for the combination of conceptual history and experimental design, theory and argumentation, metacognition and educational transposition and the relationship among science, culture and society.

In this regard, knowledge of the historical evolution of the issues that make up scientific culture provides a greater opportunity to 'devise' new strategies and educational objectives, the purpose and the reason for educating in science, that is to say, what is the importance of scientific education in our present society? Who is science for? What ideas and values underlie research practice? Does the available scientific and technological knowledge foster a way of thinking and acting for social change and the improvement of the quality of life and the environment?

71.6 Conclusion

The last 20 years has seen a significant rapprochement between the area of science education and HPS. Advocates of the incorporation of aspects of the HPS into science teaching, even though they are aware of the existence of differing opinions, stress the importance of a contextualized approach to this topic. That is to say, teaching science in a way that would allow students to carry out a critical analysis of the fact that the social, historical, philosophical, ethical and technological context is closely linked to the development, validation and application of scientific knowledge.

However, it is worth pointing out that, as Matthews (2000) states,

> It is unrealistic to expect students or preservice teachers to become competent historians, sociologists, or philosophers of science. We should have limited aims in introducing questions about the nature of science in the classroom: a more complex understanding of science, not a total or even a very complex, understanding.

Nevertheless, it is essential to consider in greater depth the reformulation of curricular projects at the different education levels – including science teacher colleges of education – taking into account the evaluation of the results obtained from them. At the same time, it should, on the one hand, be necessary to consider the possibility of training practicing teachers who as undergraduates never had the opportunity to approach the issue from this perspective. On the other hand, a greater production of written teaching material for students as well as for teachers should be beneficial. In recent years, there have been a growing number of research studies of science education that present teaching units for different science topics within a historical and epistemological context and that take account key aspects of the NOS. However, only a few of them transcend and reach teachers, pre-service teachers and students.

If one examines the aspects of NOS that have been incorporated into curricular designs during the last twenty years in Argentina, one notices a significant development. At the same time, research work in the subject has increased, and teachers are kept informed about the results of such research through national magazines, among others. However, it is necessary to promote other training instances for those in-service teachers who have no access to these publications or conferences. This is essential if it is our aim to form scientifically literate citizens.

Irene Arriassecq is professor in physics and mathematics, and member of the Teacher Training unit at Universidad Nacional del Centro de la Provincia de Buenos Aires (UNICEN), Argentina. She received her B.Sc. in Physics, M.Sc. in epistemology and methodology of science at Universidad Nacional de Mar del Plata and Ph.D. in science education from Universidad de Burgos, Spain. Her present research interests include the use of the history of science and epistemology in physics education and the design of teaching-learning sequences for physics education with focus on teaching and learning of special relativity theory in high school level. She has published in the area of physics teaching in journals such as *Science & Education, Revista de Enseñanza de las Ciencias, Caderno Catarinense, Ciência & Educação, Enseñanza de la Física, Revista Electrónica de Enseñanza de las Ciencias and Revista Investigações em Ensino de Ciências*, among others.

Alcira Rivarosa is senior professor of didactic and epistemology and history of science in the Department of Natural Sciences in the Faculty of Exact, Physical, Chemical and Natural Sciences at Universidad Nacional de Rio Cuarto (UNRC), Argentina. She received her B.Sc. in biology, M.Sc. in epistemology and methodology of science and Ph.D. in science education from Universidad Autónoma de Madrid, Spain. Her present research interests are related to teaching and learning biology. She has published six books, ten chapters as co-author and more than 35 papers in the area of science education in national and international refereed journals.

Chapter 72
Ernst Mach: A Genetic Introduction to His Educational Theory and Pedagogy

Hayo Siemsen

> *An effect size of d=1.0 should be regarded as large, blatantly obvious, and grossly perceptible difference.* Jacob Cohen (1988), "inventor" of the meta-analysis
>
> *[…] one gets large numbers when one weighs an elephant with gram weights.* An eminent statistician in defence of the dissertation of Wertheimer's assistant Luchins after one year of discussion about a possible error in it

72.1 Introduction and How to Read the Article

This article will attempt to provide a genetic introduction to the ideas of Ernst Mach, especially concerning education. It does not include a biographical overview on Mach as this can be found in many other sources (see end of the article). The first part of the article will give an introduction on how to read it (and why it is important to know). The next part will then provide an overview on the teaching phenomena associated with Machian teaching. These phenomena tend to be far away from most teachers experience with teaching. Even supporters of Mach often do not believe that such phenomena are possible. Therefore, the following part is concerned with the empirical evidence showing why the difference from an exponential teaching model to a standard linear teaching phenomena is so large ("[…] one gets large numbers when one weighs an elephant with gram weights", see Luchins 1993, p. 162). After that, the main idea of Mach is elaborated, i.e. why he changed from the antique understanding of genesis and adapted to a post-Darwinian concept of genesis. The main implications of this adaptation are then elaborated: sensualism,

gestalt[1] (economy of thought) and *erkenntnis* theory.[2] Finally, Mach had several successors, whose teaching one can use as empirical examples of Mach's educational meta-method.

Understanding Mach's ideas is very challenging. This can be seen from the many, often contradictory attempts of eminent scientists to do so. Why is it so difficult? Mach integrates facts, phenomena and observations from many different sciences as well as pre-scientific ideas. His goal is to provide *general* concepts, applicable for and consistent with the knowledge from all sciences and all experience. They are thought economical, i.e. one concept can be applied to many or – if possible – all fields of knowledge.

In order to achieve this, Mach takes a fundamentally different world view. As he emphasises, this is not a necessary view. Other views are possible. Like one can see the movement of the solar system and the stars from earth in a geocentric, Ptolemaic view, or one can view it (as a fictional thought experiment) from the sun, a Copernican heliocentric view. For Mach the difference is mostly an economic one. Each view serves as a yardstick, a "currency" by which concepts are "exchanged", i.e. related to each other. For some measures, one view will be the more economical, e.g. practical; for other purposes, another view might be more central. The sun – because of its high gravity – influences the other planets much more than they influence each other, except for those close to each other, like the moons to their respective planets. Therefore, the movements of all planets are easier to understand from a heliocentric view than from a geocentric one. But for the observation of the moon relative to the earth (e.g. for sending a rocket to the moon), a geocentric point of view is often the easier, more pragmatic point of view. Flying over the Atlantic, one rarely bothers to imagine or even calculate the distance via the sun (*Helios*). Likewise, Newtonian physics is mostly sufficient for such a flight, though maybe not anymore for moon or space travel.

Points of view thereby serve as "currencies of exchange" between concepts. They provide a single theoretical point, through which one can compare the relations of many or all observations, just as one can value all kinds of goods via one currency. Without a currency, i.e. in a barter economy, one has to remember how many oxen have the value of a horse and how many sheep have the value of two horses as well as how many sheep one can trade for an ox. If one now imagines that there are not only oxen, sheep and horses but also different qualities of cloth of different width to trade with the service of bringing the oxen to my farm passed the raiders on the road, etc., the value of a standard currency for the economy of memory and calculation becomes obvious.

Such a currency of course is most valuable, if one can use it very broadly. The Euro and US dollar have their respective "usage" value not only because of some gold reserves but also because they are used in many places by many people. Applying this

---

[1] For Goethe a *gestalt* used to be a "whole". Mach changed this into a genetic understanding of the concept, where a gestalt is like a species. It can adapt and transform; it is a process and a product (plasticity). Why it is thought economical will be explained later.

[2] *Erkenntnistheorie* in German means something in-between theory of knowledge, cognition and epistemology, though it is neither of these.

analogy to making concepts comparable over many disciplines, Mach's world view is optimised to represent the most economical view.[3] Mach's world view consistently comprises most known facts from all different areas of human experience. Experiences from different domains can thereby not only be compared but also be used complementary; reciprocally, they can "inform" each other. The relation between concepts is always possible via the currency. The basic concepts forming the world view are explicit as far as possible, including pre-scientific, intuitive concepts. If one does not do this, like in many speculative theories, a single mistake or inconsistency in the beginning can metastasise manifold and – as in the case of the Euro in 2012 – come back to haunt the founders much later.

A singular view furthermore generalises many concepts so that few concepts can stand for many facts. One idea, once thought, just needs to be reproduced from memory and applied everywhere. This application is not just analogous, but is based on the most general facts and experiences. Like the Euro, it requires a larger investment in the beginning, because many existing currencies need to be replaced and – also like the Euro – it as well requires "political" (philosophical) adaptations of many pet ideas held dear.[4]

In what way is the psychophysical[5] world view which Mach proposes more consistent than other views? The view comprises the physical view (about the world) and the psychical view (about ourselves and how we individually experience the world) into a singular meta-perspective. This singular general perspective is called monistic.[6] In order to be able to say something about the world, one needs to have a physical theory. This theory is first of all a private theory. It might – depending if and how much one studied physics – be naive or more sophisticated. Sophistication here only denotes how much the theory will cover regarding potential experiences. Will it still work when applied to a double-slit experiment? Will it still apply to the workings of CERN? Few people in the world will have developed their physical theory to the latter. If the physics of tomorrow is different from today's, such a view might also then become quickly outdated.

---

[3] This is why Mach acknowledges that there are several world views possible, but others are optimised for other criteria. It would of course be scientific to always make these criteria explicit so that one can compare the motives.

[4] This often causes – sometimes very sudden and fierce – emotional rejection of the ideas. One feels like the previously sturdy floor on which one learnt to walk is suddenly pulled away underneath one's feet. Siemsen et al. (2012) call it the "rug of horror" symptom, describing the emotional trouble of some students facing up to some of their lifelong inconsistencies in learning. The mathematician Weyl (1928) put it in a different metaphor when the sturdy mathematician's "tower of knowledge" is "turned to mist". Kurki-Suonio recalls that the in-service teachers he taught always showed one year (in a two-year course) of "resistance" before a gestalt switch in their world view (for the technical details how the course was implemented, see Lavonen et al. 2004). The older one gets, the more one tends to become emotionally attached to often used habits of thought.

[5] Mach's generalised interpretation of psychophysics as a world view is unusual, also in psychophysics.

[6] This is not necessarily contradictory to what William James called a "pluralistic world view", because Mach's view deliberately comprises different perspectives. Mach makes them comparable, without claiming absoluteness, just economy.

On the other hand, as humans we also require a psychical view. Otherwise we cannot conceptualise other humans (and ourselves as different from them). Such a "theory" in its rudiments is formed in very early childhood (when the child starts to communicate and interact with its fellow human beings).[7] Later, this "naive" theory might become more sophisticated through systematic psychological observation and experimentation, i.e. by a "scientific" psychical theory.[8]

What Mach now proposes is to combine the physical and the psychical view[9] into a singular world view (general or meta-perspective). Although such a singular view is again very close to the initial perspective of a baby, we could not have acquired it without having previously gone through many human experiences. This view is an abstraction derived from these experiences.

One needs to shift one's view away from a mainly dualistic view in which one sees the "world" and the "self" as separate entities, towards a monistic view. In a Machian monism, one assumes the relations between the "world" and the "self" as the basic elements. One can only know that there is such a relation. What one learned to know as the "world" and the "self" are then only intuitive constructs of such relations from childhood.[10] In order to know, what the relation is, one has to apply the physical view and the psychical view, like standing on and walking with the left as well as the right leg.[11]

---

[7] Thereby, Mach's psychical theory is first of all a theory of the individual, not of the "self". The "self" in his view is just one outcome, a construct of individual (sensual) experiences.

[8] The process of science for Mach consists in a higher economising by systematically using and testing the experience of many people and making them comparable though a more standardised framework of observation.

[9] For this, one should take more sophisticated and consistent versions of these views in order to consistently cover many facts and human experiences.

[10] "Every human discovers within himself, when waking up to his complete consciousness, already a completed image of the world, to which accomplishment he did not at all willingly contribute to and which he accepts on the contrary as a gift from nature and of the civilization and as something immediately intelligible. This image was built up under the pressure of the practical life; extremely valuable, in this regard, it is inerasable and never ceases to act upon us, no matter which are the philosophical views that we will later adopt". "Here everyone has to start" (Mach 1905, p. 5).

[11] "For most natural scientists and many philosophers, who do not admit it, the thought that all psychical could be deducible to the material is very congenial in private. Even if this materialism has a catch, it is not the worst possibility; it stands at least with one foot on secure ground. But if all psychical should be understandable physically, why not the other way round? […] Is the other [psychical] foot standing in the air? I would prefer […] to stand on both feet. […] There is no necessity to become dualist thereby for the one, who considers both feet as equal and both floor spaces under the soles to belong not to two different worlds" (Mach 1920, p. 434; 1883/1933/1976; 1883/1893/1915). In his book *Knowledge and Error* (1905), Mach uses such a dual approach, switching back and forth between a physical and a psychical perspective. This (and other unusual features) seem to have been unfortunately too much for instance for the translators (in English as well as in French) to cope with. Especially the translations of his books have led to many unfortunate misunderstandings of Mach's ideas (except for the excellent translation of *The Mechanics* by McCormack and Pierce, though that has suffered as Jourdain complained from not being updated to the many further developments Mach included in the later German editions).

Mach calls this relation "sensory element". He states that he could interchangeably call it "physical element", though then people would easily mistake it for physicalism. The relation is very broadly defined, including the sun lighting the perceived object as well as the memory (and prior experience), which makes the object recognisable. These psychophysical relations thus have a genesis, which needs to be researched. What one perceives as simple relation might actually under scrutiny turn out to be a cluster of relations. The sensual elements are therefore recursively defined. Although the relation is "immediately given" as a gestalt, this perceived "immediately given" represents only one side of the relation. The "given" is not simple, but requires many perspectives of research of which none can ever supposed to be final. Even the habitual separation of sense elements into senses might already be too much reductionist or too little. One cannot know a priori, one can know only genetically. Sensual elements are gestalts, i.e. they adapt and transform like species.

Other monisms of course exist, namely, physical monism (materialism or physicalism), which presumes that all psychical phenomena are epiphenomena, and the "panpsychism", which supposes that everything is initially psychical. There are also more or less arbitrary combinations of the two, delimiting the rule of one relative to the other (James noted that some monisms are actually dualisms under disguise). Finally, there are the "parallelisms", which suppose that the physical and the psychical always go together "in parallel", like a tandem. But as one might notice, Mach's feet will rarely work "in tandem", i.e. hopping together, but rather complementing each other while walking (Mach used the metaphor of a "tunnelling" between the two perspectives, i.e. a process, which brings them continuously closer together). Mach's psychophysical relation is only the starting point of genetic (and other) enquiry.

The "problem" of this shift in world view is one of learning in general. As one learns a different way of learning, one has to discard previous ways of learning or at least to adapt them to the new framework. Learning methods tend to be well associated (neurally connected), because of the high frequency of learning in general. Changing these associations is more difficult than regular learning. It is not only learning something new but resembles changing early childhood experiences, like sometimes done in psychotherapy. There are hints that such meta-learning involves not only changes in neuronal connections but also actual formation of new neurons on a scale not regularly observable in learning processes (see, e.g. Buonomano & Merzenich 1998).

The view presented here is not a standard (formal) account of Mach's ideas. It is a genetic introduction to Mach's ideas. New concepts will be introduced genetically, i.e. starting with a more standard meaning and then successively being transformed into Mach's usage. As several of the main concepts, such as *erkenntnis* theory, genesis and world view, are reciprocal, i.e. have to be developed interdependently, they need to be introduced before each concept is fully developed in its new meaning. One thereby has to read the text several times. The first time, the footnotes can be left out. In the second reading, they provide additional facts and information for further transforming some important main concepts. In a third reading, one can therefore focus mainly on the footnotes and skip through the main text. If possible, one should also leave a night in-between these readings. On the next day, one will be able to identify the less well-understood parts more clearly.

72.2 The Phenomenon of Genetic-Adaptive Learning

William James called the lecture he heard from Mach "one of the most artistic lectures I ever heard" (Thiele 1978, p. 169).[12] What constitutes this artisanship of teaching? James (Thiele 1978, pp. 169/173) later tried to copy this method as well as Mach's world view in teaching his students: "I am now trying to build up before my students a sort of elementary description of the construction of the world as built up of 'pure experiences' related to each other in various ways, which are also definite experiences in their turn. "There is no logical difficulty in such a description to my mind, but the *genetic* questions concerning it are hard to answer." I wish you could hear how frequently your name gets mentioned, and your books referred to". James thereby encounters some effects of genetic teaching, which – when compared to other cases of Machian teaching – seem to be typical, including the difficulty of implementing the genetic questions (as Mach had noted – see later quotation – this can be as challenging as finding the idea in the first place). What are the typical effects of genetic-adaptive learning?

Intensive (transformative) experience: There are accounts of people who have been influenced by Mach and genetic-adaptive learning by just two hours (Siemsen 1981), an oral exam (Heinrich Gomperz), even of 10 min (in the case of Karel Lepka[13]) or hearing one lecture from Mach (Fritz Mauthner, one of the founders of linguistic critique, see Siemsen 2010a). This short time was sometimes enough to change the lives of the people involved (for instance, when Karl Hayo Siemsen met Joachim Thiele[14] once for two hours, but now considers himself following in his footsteps). Also people who have been influenced by Mach, such as Schumpeter, are known to produce this effect.[15]

---

[12] Mach's way of learning will in the following be called "genetic adaptive". Such learning should be viewed like a Darwinian species: a process and a product. The growth processes are exponential rather than linear; they adapt and transform. Therefore, some empirical results from such learning might look extreme and unbelievable to anybody who has never observed them. Nevertheless, over the last 150 years, there have been many such empirical observations in many contexts, mostly influenced directly or indirectly by Mach.

[13] Lepka is professor for mathematics education at Masaryk University, Brno, CZ. He described this occurrence in detail in several interviews 2011/2012. Several other students of ernohorský have described similar, though a bit less extreme effects.

[14] Thiele first systematically published Mach's letters. From this work he gained important insights on Mach missed by many other Machian scholars.

[15] This effect and several of the following effects can certainly be observed in other circumstances, which have no Machian background. Nevertheless, some of the following effects are unique. Others are unique in their combination, frequency of occurrence or reproducibility. In all known

Inspiring eminent new ideas in multiple areas: In principle, this seems to be a corollary of the transformative experience described before (though in many cases, it has not been properly described). Few people have influenced so many eminent other people than Mach. Maybe the last time this has happened in human history were the many schools of thought founded after Socrates (and maybe the many ideas Galileo inspired; though in that case it is difficult to trace this effect mainly to Galileo). Mach has directly or indirectly influenced not only a handful but also many Nobel Laureates, even much after his time and not just from one area, but all areas in which such prizes are awarded.[16] Einstein (1916, p. 102) provides a metaphor for this type of intuitive influence. Regarding his own generation of physicists, "I think that even those who think of themselves as enemies of Mach, don't remember how much of Mach's approach they have – so to speak – imbibed with their mother's milk".

Aspects of this "mother's milk effect" can be found in several areas, methodology, epistemology, praxis, etc. For instance, according to Einstein (1916, p. 102/103), it "trained [the physicists] to analyze the long-time prevalent concepts and to show, of which circumstances their eligibility and usefulness depends upon, how they have grown in detail out of the conditions of experience. Thereby, their excessive authority is broken".

The mother's milk did not start with Mach's famous *Mechanics*. There was a genetically even earlier mother's milk for many eminent scientists in German-speaking countries. The effect was transmitted through Mach's schoolbooks, which they grew up with (and certainly could not remember consciously) between 1886 and 1919.[17] They already learnt the concepts the Machian way. Even though some, like Planck, later criticised aspects of Machian ideas, they still intuitively retained and used nearly all of his *erkenntnis* theory (see Siemsen 2010c).

This did not only happen in physics but also in chemistry (where, for instance, Wilhelm Ostwald was close friend and admirer of Mach) and biology. Especially in medicine, Mach's teaching of "physics for medical students" in his *Compendium* (Mach 1863) had long-term effects, as many medical students were travelling all over Europe during their study times. As other eminent scholars – even such as the likes of Wundt – did not have a consistent *erkenntnis* theory of their own (as James had noted), the students coming out of their labs were mainly Machians, at least in their *erkenntnis* theory (such as Kuelpe or Titchener, see Boring 1950/1957).

Machian teaching phenomena, several of the effects have been observed, while other effects might have been overlooked as the effects have never been systematised.

[16] For example, Einstein, Pauli, Bohr, Planck, von Laue, Raman, Heisenberg, Rabi, Bridgman, Ostwald, Arrhenius, de Broglie, Landau, Ramsey, Polanyi, Wilczek, Eigen, Lorenz, Musil, Bergson, Hayek, Samuelson, Simon and Coase. No systematic inquiry has yet been made on many others. Especially, it would be interesting to know how many winners of the "physiology or medicine" prize have been in Mach's "physics for medical students" lecture. Probably there are several. Mach himself was suggested for the prize but probably was too much of a generalist for a specific prize. There is no Nobel prize for *erkenntnis* theory.

[17] See Siemsen (2012a) or Hohenester (1988).

Also many eminent economists, such as Schumpeter, Hayek, Georgescu-Roegen, Samuelson and Polanyi, took a deep zip of Machian mother's milk. Even many artists were not free from this influence. Some, like Schnitzler or Hofmannsthal, had even been attending Mach's last lectures in Vienna, while the literature Nobel Laureate Musil wrote his dissertation on Mach. There were also influences on linguists (Mautner), philosophers (Wittgenstein, Feyerabend, Popper, Vaihinger, Radulescu-Motru), sociologists (Zilsel, Cohen, Neurath), mathematicians (Poincaré, Nevanlinna, Haret, Hadamard, Hahn, Menger, Weyl, Brouwer, Mandelbrot, Marcus and 65 recent mathematicians and maths teachers, see Ahlfors et al. 1962), historians (Sarton, Koselleck), anthropologists (Boas, Lowie, Malinowski and through their students also Jerome Bruner), biologists (Loeb), logicians (Pierce), philosophers of science (Frank), etc. (see Holton 1992; Siemsen 2010a, d).

Why has Mach's central role in these general aspects often not been properly described or even recognised? Einstein gives a hint when he tells his friend Besso in 1948 (Speziali 1972, Doc. 153), "Now, as far as Mach's influence on my development is concerned, it was certainly great. [. . .] How far [Mach's writings] influenced my own work is, to be honest, not clear to me. In so far as I can be aware, the immediate influence of D. Hume on me was greater. [. . .] However, as I said, I am not in a position to analyze what is anchored in unconscious thought".

Teaching is mostly intuitive: As Einstein had so aptly described with his "mother's milk" metaphor, much of Mach's teaching "becomes anchored" on the intuitive (nonconscious) level. This is a corollary of the intensive sensualism involved. The sensual relations belong to some of the oldest biological setup and are therefore mainly connected with consciously not easily accessible parts of thinking. To make them accessible to reflection is a task of *erkenntnis* psychology, which is unfortunately the least understood and reproduced element of Machian teaching. Kurt Lewin aptly called the result "practical theory".

When Mach's *erkenntnis* theory is acquired early, the transformative effects are not experienced as special. One might only later be surprised that other people's thinking is not the same. What is "normal" and therefore not special about teaching in Finland may be unique in the world. When asked what is special in their teaching, Finnish teachers are often not able to answer this question, or the theory provided might have little correlation with the actual phenomenon. Scientists (influenced by Mach) might intuitively know what to do and what works. When one follows their (later constructed) theory, one unfortunately cannot reproduce their results. What works for them works because of effects not covered by their theory (cases of this are, for instance, Piaget or Wagenschein, see Siemsen 2010b, 2012b).

Teaching becomes mostly independent of age and "stages": One of the theoretical (metaphysical) elements Piaget popularised in science education is the model of the "stages" of development taken from the intelligence scale of Alfred Binet. The stages are teleological, i.e. depend on a specific definition of culture and intelligence. They are not genetic. Mach instead describes the genetic process of popularisation:

> Once a part of science belongs to the literature, a second task remains, which is to popularize it, if possible. This second task also has its importance, but it is a difficult one. It has its importance, because – regardless of the distribution of knowledge that increases its value – it

> is not unimportant either for the further development of science itself how much knowledge has been disseminated into the public. The difficulty is to know the soil very well in which one wants to plant the knowledge.
>
> It is a prevalent but wrong opinion that children are not able to form sharp concepts and come to the right conclusions. The child is often more sensible than the teacher. The child is very well able to comprehend, if one does not offer too much new at a time, but properly connects the new to the old. The adult is a child when facing the completely new. Even the scholar is a child when confronted with a foreign subject. The child is a child everywhere, as everything is new to him. The art of popularization lies in avoiding too much of the new at one time.[18] (Mach 1866, p. 2–3)

Can this be observed empirically? For example, the physics Nobel Prize winner Wolfgang Pauli was godchild of Mach (born Pascheles, the family, especially the father, were close friends of Mach). He received *The Mechanics* (Mach 1883) as a gift from Mach when he was 8 years old. Another example is Peter Drucker, an eminent management "guru", who describes in his autobiography, how his 1 year of school in fourth grade in the Schwarzwald School[19] changed his life (Drucker 1979, pp. 62). He later adapted and used the methods he learnt in this year in school to management (see Eschenbach 2010).[20] They became some of the most influential ideas in modern management.

"*Bad" students suddenly become "good" or "very good"*: The "shift" of students improving in grades is not only by one to three grades (on a 5–1 or 0–6 scale), but can happen in "jumps". In many instances, for example, in Finland, but also for Siemsen et al. (2012) or Gabriel Szász,[21] initial "laggards" suddenly become excellent students. They thrive with the new method.

Alfred Binet, the "inventor" of the intelligence test and the concept of age-related "stages", which was later perfected by his student Piaget, late in his life worked specifically on the "laggards", i.e. the lowest 5–10 % on his intelligence scale. After a discussion with Mach, whom he had invited to write an article for his "*L'Anneé*

---

[18] Instead of age groups and stages, the pre-knowledge ("not too much new at a time") becomes a more important factor. Some pre-knowledge might be enabling, some obscuring for the new *erkenntnis* process.

[19] One of the schools inspired by Mach.

[20] Another example is a girl of 3 1/2. She was supposed to learn about opera. After intensively using first very simple versions of the "Magic Flute" by Mozart (abridged puppet and children's versions), connecting these to previous experiences and repeating scenes as requested by the child, it became possible to watch a regular version of the Magic Flute. Now the question was if one could directly present her a "difficult" opera. One of the most challenging operas is certainly Wagner's "Ring des Nibelungen" (at least concerning the length and the complexity of the story, though also the music is challenging compared to Mozart). She loved it and though she was allowed to watch only smaller parts of the total 16 h at once, she always wanted to continue and remembered the scene where she had to stop before. Also she developed favourite scenes to be repeated and started to recognise gestalts from the opera in daily life. What was new for her was the medium of opera. Once she knew the basis of it very well, expanding (exponentially) from this basis was not a problem, neither of learning, nor of age.

[21] In courses on astrophysics at the Masaryk University in Brno, Czech Republic, 2008 and 2010 (see http://astro.physics.muni.cz/iwssp2008/ and http://astro.physics.muni.cz/iwssp2010/, accessed 25/08/2012).

Psychologique" (see Siemsen 2010b), Binet developed the concept of "mental orthopaedics" (*orthopedie mentale*) specifically for this problem. Mental orthopaedics is an application of psychophysics to learning. Unfortunately, Binet died shortly after implementing this idea for a larger number of students, but the rector of the school with whom Binet worked published some empirical results posthumously (Vaney 1911). The results show not only a very fast relative but also an absolute "catching up" of most students compared with the regular students (the school got the students only after a minimum of 3 years of "lagging behind" in a regular school, but many of them were on the same level after 2 years of mental orthopaedics). Additionally, although the singular "curves" seem to be linear, taken together they show a clear exponential component in learning.[22]

The phenomenon of the thriving students also shows that empirically, the so-called Matthew effect in education,[23] i.e. that good students tend to get always better and laggards continuously lose out on them, is actually not a fact, but an artefact of a linear learning paradigm.

Learning happens without outside pressure: The students themselves perceive this way of learning mostly positive (in spite of the previously described "rug of horror" effects), because there is no external pressure necessary for learning. The pressure and motivation becomes intrinsic, i.e. self-organised (see Siemsen et al. 2012). As a result, also motivation is not a problem anymore. All students want to learn, and the problem is mostly to limit the time for learning so that they have enough time for intuitively digesting what they have learnt while doing other recreational activity. Some adaptation of the thoughts to each other needs to take place overnight during sleep.

Time perception changes in learning: One indirect consequence of genetic-adaptive learning is the relativity of time perception in learning. Because the learning process

---

[22] The details will be elaborated in a separate article following more detailed research. Karl Hayo Siemsen stated in a personal message that Binet basically used the same method as he used (Siemsen 1981), but 60 years earlier. Just that Binet used school instead of university students, but with very similar empirical results (Vaney 1911). This finding would imply that Mach, James and Binet, the eminent researchers in the German-speaking countries, the USA and France at the time, were all using in principle the same method as ideal teaching method. It seems unfortunate that the method got lost nevertheless, probably because James and Binet developed it only at the end of their lives, with the chaos of the world wars ensuing shortly afterwards. Thereby, the method was never even properly identified as a specific method with specific phenomena.

[23] The "Matthew effect" was first coined by Robert K. Merton in order to describe, for instance, that eminent scientists tend to get more credited for the same work than unknown ones. "For unto every one that hath shall be given, and he shall have abundance: but from him that hath not shall be taken even that which he hath" (Matthew 25:29, King James Version). This idea was then applied to education by Keith Stanovich regarding reading literacy. But the actual story is probably more intricate. A little bit before, Matthew also entails a "counter-Matthew effect": "But many that are first shall be last; and the last shall be first" (Matthew 19:30, similar in 20:16, King James Version). Maybe one should rename the effect in education instead into "Hit-The-Luke" (translation of "*Hau-den-Lukas*", the German name for a "Ring-The-Bell" at funfairs) for all the students who are never taught to become very good students.

is so intensive, the thoughts related to the learning process become dominant versus other background thought processes, such as the one keeping time.[24]

Learning takes place in genetic "loops": Genetically, many ideas and concepts cannot be introduced at once, but need repeated scaffolding and auxiliary concepts in order to develop. In such "groping phases" (Kurki-Suonio 2011), sometimes little seems to happen on the surface, while "suddenly" gestalt switches of whole ranges of concepts appear. This effect has also been described by Poincaré (1908) for how he found new mathematical functions for which he became famous. Contrary to common belief, such intuitive thought processes can be observed, measured and consistently reproduced (see Siemsen 1981, 2010a; Siemsen et al. 2012).

Genetic "loops" have been used by Mach already in his schoolbooks, but they become imperative for meta-learning as Mach describes: "The value of such general methods lies in the economization of thinking about the single case, in the easy templating of it. This cannot be understood, unless initially a whole host of single cases has been sufficiently dealt with through the consideration of very different details. More general methods in science are a result of much detail work and have to be this also in teaching. Without this, method is an un-comprehended gift. In the method lies the insight that one can think a thought one-and-for-all and does not have to think it again in each case. […] 'What you have inherited from your forefathers, gain it in order to own it'" (Mach 1876, p. 13).

Long-term and transfer effects: From the observations by Kurki-Suonio, Siemsen and ernohorský, but also from the Schwarzwald School (see, for instance, Siemsen et al. 2012), a student only has to pass through a teacher with genetic learning one time during his life and can afterwards apply the genetic learning as meta-learning on all other learning throughout his or her life. Siemsen et al. (2012), for instance, have shown strong transfer effects, where the *erkenntnis* theory taught in a project study reduced the percentage of students not passing a mathematics exam from 90 % to 40 % without any teaching of the contents of "higher mathematics 1" or the mathematics teaching being a core topic in the project study. The empirical results of the experiment of Siemsen from 1981 suggest that with some genetic mathematics teaching (2–4 h), this with 40 % still high dropout rate can be brought down to nil. Similarly, the long-term effect of genetic-adaptive teaching seems to show in terms of personality development. This is documented for many cases of the Schwarzwald School as well as students of ernohorský and Siemsen. Surprisingly many of them become professors, entrepreneurs, eminent writers, politicians (ministers and prime ministers), etc. When interviewed, they tend to agree that this teaching has had a very important effect on their career.

Exponential learning: If one compares the empirical effects of methods based on linear models of learning, one typically arrives at meta-analysis effect sizes of d between 0.0 and 0.6, sometimes up to 0.8 (see Hattie 2009).[25] Jacob Cohen (1988),

---

[24] This effect is, for instance, also described by Csikszentmihalyi (1990) with his concept of "flow".

[25] Hattie (2009, 2012) comprises more than 60,000 empirical analyses on student achievement from more than 900 meta-analyses onto one scale of comparison, which is the effect size (after-before or

the "inventor" of the meta-analysis, argued that an effect size of $d=1.0$ should be regarded as "large, blatantly obvious, and grossly perceptible difference" (quoted by Hattie 2009, p. 8). This is as perceivable as more than 20 cm difference in the height of persons. Finland as a field experiment (OECD Pisa 2006) has a $d=1.0$. The problem can be that many teachers have never observed effects even close to this and therefore may regard such effects as "unbelievable",[26] contrary to Cohen's view.[27]

72.3 Empirical Observations When Changing to Machian Teaching

What happens if one changes to a Machian teaching? As Mach (1886/1893/1986) described, "I know of nothing more terrible than the poor creatures who have learned too much. Instead of that sound powerful judgement which would probably have grown up if they had learned nothing, their thoughts creep timidly and hypnotically after words, principles and formulae, constantly by the same paths. What they have acquired is a spider's web of thoughts too weak to furnish sure supports, but complicated enough to confuse".

Mach sees teaching very empirically. Today, most teachers experience that they have to teach too much in too little time. But this is an empirical illusion created by the standard (linear) teaching model. Martin Wagenschein (1970) suggested a simple empirical test against this misconception. How much knowledge is really taught, i.e. how much "remains" in long-term memory? Everything that is forgotten is obviously superfluous to teach in the first place. One can just repeat the test one does at the end of the course and repeat the same test 2 weeks after without telling the students beforehand. Repeat the same test after a year. How much of the apparent knowledge remains? On average it is just about 5–10 % (even if it would be

---

experimental-control group divided by standard deviation). Meta-meta-analyses also provide an interesting opportunity for conceptual analysis and finding inconsistencies in the empirical meaning of concepts. If the results of different meta-analyses for one concept vary largely, this might be because the description of the concept or the concept itself is inconsistent or confused, leading the studies about it into different interpretations or into white noise.

[26] For an example, see Luchins (1993), the assistant of Wertheimer in the USA, recalling the problems with his dissertation about rigidity, which seemingly included exponential effects. This is an important reason to make statistical analysis of Mach's teaching method, because it grossly violates the gut feelings (intuitions) of many experienced educators. People with less experience have less trouble accepting it. The problem also effects student's evaluations of this method, because also their intuitive model of learning is linear, which leads to conceptual inconsistencies when confronted with exponential learning effects (see Siemsen et al. 2012).

[27] This "unbelievability" also happens in the method of meta-analysis. Typically the "outliers", i.e. the most extreme effects, are sorted out. Unfortunately thereby, if any Machian teaching effect was ever initially included in such a study, it will probably not have been further researched as best practice, but statistically eliminated.

50 %, still half the teaching is a waste of time).[28] So from an empirical standpoint, one should teach only the knowledge which is later present in memory and use the rest of the time of the course otherwise. The 95 % which is forgotten is a waste of time anyway, of the teacher and of the students. This is how one can teach more within less time.

This "watering down" effect of knowledge taught to (less) knowledge used is actually taking place severalfold throughout the education process. According to inquiries (by Mueller-Fohrbrodt et al. 1978), teachers tend to run into a "shock" of praxis after their theoretical education at university. They adapt mostly by throwing away what they learnt at university (see Mueller-Fohrbrodt et al. 1978). Teacher education has little effect on student performance (d=0.11, see Hattie 2009, p. 110). Professional development might still have a high effect on teacher knowledge (d=0.90 probably measured for short-term and not long-term memory and effects), but this is less implemented (d=0.60) and has even less influence on student learning (d=0.37, probably also short term, see Hattie 2009, p. 120). The experience of Kurki-Suonio (2011) in his in-service teacher training courses are that the Machian world view is more difficult to teach to teachers in the first place (high initial resistance/rigidity), but then the new gestalt is much more stable. It also leads to much higher student learning (d=1 long term for all of Finnish students with only 1/3 of Finnish science teachers trained in this way, see OECD 2007 and Siemsen 2011).

Mach describes the role of the teacher relative to the subject matter: "If now the teacher, who can present to himself the whole subject matter, subsumes a theorem adapting it to his *own* conceptualizations and to his *own* satisfaction of needs, then therein lies, if it happens unconsciously, certainly an error in the person whose satisfaction of needs is central in this case. If it happens on purpose, it is a didactical insincerity. For the student, premature completeness and logical finesse is useless and without any value, often even detrimental" (Mach 1890, p. 2/3). Why are 95 % of teaching used for teaching short-term memory? For the satisfaction and exculpation of the teacher, so that he or she can claim to have "taught everything"?

Empirically speaking, most of lecturing at schools and universities is wasted. Instead, one could free time for effective learning in the way described above and reduce overall time spent at school and university. In logistics, this radical approach of quality improvement is now standard. Quality management is not mainly about certification and formalising processes.[29] It is about reducing (or rather preventing) faulty products and processes.[30] In education, one could say that many products pass

---

[28] One could call this test "Wagenschein's razor".

[29] "[…] control charts are justified for only a small minority of the quality characteristics" (Juran 1951, p. 308).

[30] Joseph M. Juran (1951, p. 247), one of the early "gurus" of quality management, wrote about "the principle of prevention" that "It needs no argument to conclude that it is better to prevent defects from happening than to sort them out after they have happened. Shop supervisors and personnel are fully aware of this principle. The failure to apply the principle of prevention lies *not* in any disbelief in the principle. Rather the problem is one of *how to achieve* prevention. Any lack of achievement is in turn not the result of deliberate (or even unwitting) resistance by individuals; it is rather the result of the limitations of modern industrial organization". Juran (1951, p. 248) then

the final quality test, but still more than 90 % fail in their first application.[31] This is a huge waste.

Japanese quality improvement calls instead for the identification and reduction of "*muda*", the Japanese word for waste (see Ohno 1978/1988, p. 18).[32] Taiichi Ohno, the Toyota engineer who made the Toyota Production System (TPS or Lean Management) popular, described the success of Toyota through the reduction of three types of waste: *muri* (overburden, beyond power, by force), *mura* (inconsistency, irregularity) and *muda* (waste).[33] Applied to education it would mean that one needs to cut all learning, which (a) has to be forced on the learner, which (b) is too difficult to learn in a singular effort or which (c) entangles and confuses the students rather than enlightening them. One further has to cut all inconsistencies in

---

quotes Howell B. May (1921): "While inspection of the product is of much assistance in improving the processes, nevertheless its greatest usefulness is found in the prevention of loss from defective goods. [. . .] The success of inspection in decreasing the quantity of defective goods is based upon the fact that to maintain the necessary standards of excellence with minimum loss, the quality of the product must be known at all times". Inspection nevertheless should not be mistaken for exams and exams not with facts. "In a production plant operation, data are highly regarded - but I consider facts to be even more important" (Ohno 1978/1988, p. 18).

For achieving the compliance of students in the process, being open about not understanding something, the barrier between "work" and "fun" has to be broken down (Juran 1951, p. 269): "To the extent that a management can minimize compulsion, give impersonal supervision, allow participation in establishing objectives, provide creativeness, provide a social atmosphere, give meaning to what is being done, and provide incentives over and above money [. . .] it secures the enthusiasm as well as the compliance of the operator". It thus does not help to give bad grades for not understanding or to use grades for motivation.

[31] T. H. Huxley (1864/1870) warned in his inaugural speech as Rector of the University of Aberdeen that "examination, like fire is a good servant, but a bad master". A constant effort of passing exams has a deteriorating methodological effect on students: "They work to pass, not to know; and outraged science takes her revenge. They do pass, and they don't know". The worst is that students also do not care that they forget more than 90 % shortly after the exam. They should be the first to complain if they do not learn as it is a loss for their lives. Seemingly they do not think that what they learn is somehow helpful for their lives, for them it is just the certificate. Note: This is a part quotation only. Because of the complexity of Huxley's initial text, it is more economic to quote this way. Any reader may feel free to look up the actual quotation.

[32] The concept of "waste" was seemingly adapted from Henry Ford, who wrote a whole chapter on "Learning from Waste" in his *Today and Tomorrow*. "My theory of waste goes back of the thing itself into the labour of producing it. We want to get full value out of labour so that we may be able to pay it full value" (quoted in Ohno 1978/1988, p. 97).

[33] After WWII, the Japanese economy had only about 10 % of the productivity of the USA. The then president Toyoda Kiichiro wanted to catch up within three years in order to survive. "I still remember my surprise at hearing that it took nine Japanese to do the job of one American. [. . .] But could an American really exert ten times more physical effort? Surely, Japanese people were wasting something. If we could eliminate the waste, productivity should rise by a factor of ten. This idea marked the start of the present Toyota production system" (Ohno 1978/1988, p. 3). The Toyota Production System evolved by repeating *why* five times. "By asking *why* five times and answering it each time, we can get to the real cause of the problem, which is often hidden behind more obvious symptoms" (Ohno 1978/1988, p. 17). The idea is to separate facts from artefacts and to find solutions, which let the problems disappear. In principle, this is relatively close to Mach's idea of enlarging or transforming the view in such a way that the problem disappears.

what is being learnt as well as in the process of learning of the learner (mental orthopaedics). Finally, one should focus on the learning, which has long-term value for life and which remains in the memory of the learner (providing long-term value). The main focus has to be on a sound and consistent foundation of any learning process.[34] Currently instead, quality improvement in education seems mainly (de facto) aimed at enshrining the status quo by formalising it,[35] rather than bringing about such fundamental improvements or even to have such long-term and transformative goals.

Frank Oppenheimer, the brother of Robert Oppenheimer and founder of the Exploratorium – probably the most empirically successful[36] science museum in the world – already in 1981 described the role of the schools in being unintentionally detrimental to learning:

> A large part of the neglect [of learning opportunities such as museums in the popular mind] I think had to do with the extraordinary preoccupation of both school and college teaching faculty with the notion of certification. Educational opportunities, which did not provide any way of certifying the students or of evaluating their performance were relegated to a different domain and were not considered part of the overall process of public education. This preoccupation with certification has been, in fact, a very deadly one. It has produced generations of teachers who teach what they are supposed to teach rather than what they know and want to teach. […] In any event, since museums do not certify and the watching of television shows is not graded or going to libraries cannot be supervised, all of these adjunctive resources for public education have been neglected. [Schools] have taken on, and jealously guarded, the total job of education while having at the same time had to cope with an ever more complicated society and an increasingly mobile population. They have unfortunately failed abysmally. (Oppenheimer 1981, p. 1)

---

[34] According to Mach, all initial mistakes or unnecessary metaphysics are repeated and thereby metastasised throughout the whole process. “A problem early in the process always results in a defective product later in the process” (Ohno 1978/1988, p. 4).

[35] As Hattie (2009, p. 109/110) concludes from the meta-analyses in this area, much of teacher education is based on the gut feeling, (quoting Walsh) ““that there is presently very little empirical evidence to support the methods used to prepare the nation’s teachers.” [In my experience] every time the ‘core’ knowledge decided on by a group has been different. […] it seems surprising that the education of new teachers seems so data-free; maybe this is where the future teachers learn how to ignore evidence, emphasize craft, and look for positive evidence that they are making a difference (somewhere, somehow, with someone!). Spending three to four years in training seems to lead to teachers who are reproducers, teachers who teach like the teacher they liked most when they were at school, and teachers who too often see little value in other than practice-based learning on the job”. The challenge is to “unlearn” the perspective of teaching as a student. This requires an *erkenntnis* theoretical reflection of the teacher (who now thinks to know) to imagine the perspective of the learner new to the topic.

[36] I personally know people who have been influenced by the Exploratorium for their lifetime, for instance, becoming rocket scientists, famous writers, etc. Other typical effects and principles of Machian teaching can be found in the observations of K.C. Cole in her biography of Frank Oppenheimer “something incredibly wonderful happens” (Cole 2009). Cole wrote (email 22/08/2012) “many of my other books do [cite Mach], and that thinking came first from Frank [Oppenheimer], but I don’t remember how…”. The observation is typical for the mother’s milk effect described by Einstein regarding Mach. Before intensive research and revisiting old notebooks, also Kurki-Suonio was not aware of where he had his ideas from.

Certification[37] in education has a tendency to promote the production of large groups of below-average performing students. The method by itself does not improve understanding. The low-achieving students are sieved out, while the other part is not taught much new. Certification optimises the maximum passing of a minimum standard. If one sees certification instead as a means of providing a minimum bar *everybody* must cross,[38] finding out who still might require closer attention, at least the method is stripped off its teleology. It would mean that all students must have a minimum understanding of the topic taught. Still such a method is not genetic, though the genetic method is probably the only one providing this effect until now. Nevertheless, standard tests can be used to test genetic teaching versus standard teaching. But such tests will miss out on the most important dimensions of genetic-adaptive learning (the tests are linear, not exponential). They are a poor proxy, though students taught with genetic-adaptive teaching do not tend to have trouble passing, on the contrary.[39] Only if all students pass such tests with the highest possible grade, the tests do not make sense anymore (see Siemsen 1981). The number of students not passing shows the failure of the teacher to teach and not necessarily the failure of the students to learn. The model that the grades in a class must follow a normal distribution is a human convention, not an empirical law. It is not consistent with the teaching goal to teach everybody well.

Mach always saw exams not as a means of testing the knowledge of the student, but to teach the student something general, something the student would be able to use for a lifetime (a method, which in several cases has been described to work by Mach's former students).

For Mach, learning is a continuous activity of all living nature, not restricted to classrooms. Phenomena do not tend to adhere to scientific disciplines, but still require to be observed. In such a view, classroom activity is just a refinement of daily activity into a specific direction. There is no need for artificial borders unnecessarily separating the classroom from learning activities taking place elsewhere. It is the learning, which is the central phenomenon, not the place.

---

[37] "One has to go rather slowly on fixing standards, for it is considerably easier to fix a wrong standard than a right one. There is the standardizing which marks inertia and the standardizing which marks progress. Therein lies the danger in loosely talking about standardization. […] no body of men could possibly have the knowledge to set up standards, for that knowledge must come from the inside of each manufacturing unit and not at all from the outside. In the second place, presuming that they did have the knowledge, then these standards, although perhaps effecting a transient economy, would in the end bar progress, because manufacturers would be satisfied to make the standards instead of making to the public, and human ingenuity would be dulled instead of sharpened" (Ford quoted in Ohno 1978/1988, p. 99). Currently, no standardisation system in education is made for improving education by a factor of ten.

[38] The goal of quality management as taught, for instance, by Juran in Japan, which led to the Toyota Production System, is to optimise the process so that it has zero defects. As education is about humans and their lives, the goal of zero dropouts and even zero low achievers should be at least as important in education as in the automotive industry.

[39] In Finland, teachers from Kurki-Suonio's courses already have trouble to measure their performance, because even the phenomenology of the PISA-type tests is insufficient to measure their way of teaching.

The freed time and resources can then instead be spent on helping the students to improve their learning and improving teaching so that more than 5 % remains. In such a way, teaching can be easily improved by several hundred percent with no new resources necessary. The OECD estimates that Finnish students gain ¾ of a year on 4 years of school against German students.

72.4 The Historical-Genetic Background of Mach's Ideas on Science Teaching

What is the central change in Mach's world view in comparison to the previous (antique) world view? The main difference is the transformation in the concept of genesis brought about by many new empirical observations, which Darwin has so consistently put together in his *Origin*.

In the previous 2,500-year-old Aristotelian genetic view (based on Empedocles, see Freemen 1947/1971), animal organs (legs, arms, etc.) were initially "puzzled" together, with more or less fitting results from which only the best (the actual species, some anthropomorphic beings like centaurs and especially humans) were retained. These were the "ideal forms" (species, ideas) subsequently serving as "mould" for further copies (like a signet ring is copied into molten wax). This antique concept of genesis had quite some, but limited applicability. It would fit to some of what we would now call evolutionary phenomena, but not to others. It would explain some prenatal defects, such as Siamese twins, or cloven hands as well as anthropomorphic figures of gods with animal heads, maybe deriving from dreams or observations of masked performances. It would not fit to genetic aspects of evolution, such as fossils or species closer or less related (especially to humans). But in ancient times, such phenomena were not easily observable.

Plato developed a philosophy of knowledge in analogy to this Empedocletian hypothesis. Like the Babylonians saw the stars as the eternally unchanging and ideal gods, the Platonian universe god (in *Timaios*) was ideal and eternal. It was the signet ring, from which the earthly (wax) moulds were formed (with some errors in the process). Similarly, the godly ideas were ideal and eternal. As all souls were born with some divine essence, they could sometimes remember these ideas and thus retain them. Plato wanted to include the idea of *metempsychosis* (reincarnation of eternal souls), already much used by the Eastern religions and philosophies, into his philosophy as well.

For knowledge it meant that in humans potentially ideal (godly) thinking was degraded by earthly experience. Many of the ideas transported in myths thus become archetypes of other ideas (see, for instance, Eliade 1975/1981). Knowledge is seen as fixed forms, which do not change over time. They can only be rejected as false and replaced. Thereby, the differentiation between "true and false" becomes central. The ideas that "errors" are an integral part of knowledge and that knowledge and errors can be "good" or "less good" or "bad" (i.e. completely senseless), like gestalt psychologists suggest (see Koehler 1925/1957 or Lipmann and Bogen 1923), are not part of Plato’s system.[40] As a consequence, the logical components were given priority within the overall world view as logic was seen as god’s ideal way of thinking and detecting erroneous ideas. This view of course tends to be absolutistic rather than democratic, like the society in Plato’s Republic (see also Siemsen 2010c). One tends to claim to know the truth, while other ideas are declared aberrations. Plato’s ideal ideas cannot be developed further. They are the goal (*telos*) for any learning. For teaching, the Platonian goal is in principle already achieved and just needs to be reproduced.

Darwin (1859) in his *Origin of the Species* replaced this antique “organ puzzle” with the idea of an adaptive and transformative non-teleological process over time. Species constantly evolve in an interactive process with the environment. Organs are not puzzled together, but are formed by a long process of small adaptations, which can open new opportunities and thus “transform” into new applications. There is no godly signet ring, but each “mould’ itself creates new “moulds” (though the idea of errors in the reproduction process remains as mutations). No eternal soul needs to be transported from our “inner fish” (see Shubin 2008) to our “human form”.

What does Darwin’s view on species mean for the area of knowledge and ideas? Mach (1883/1888) in his essay *Transformation and Adaptation in Scientific Thought* generalises

> Knowledge is an expression of organic nature. The law of evolution, which is that of transformation and adaptation, applies to thoughts just as well as to individuals or any living organisms. A conflict between our customary train of thought and new events produces what is called the problem. By a subsequent adaptation of our thought to the enlarged field of observation, the problem disappears and through this extension of our sphere of experience, the growth of thought is possible. Thus the happiest ideas do not fall from heaven, they rather spring from notions already existing. (Mach 1883/1888)

As a result, Mach’s method is the genetic method of teaching, i.e. teaching as close as possible to the way how we as humans have biologically and culturally evolved. Biology and culture for Mach are reciprocal processes, which have a *plastic* result.[41]

Plato’s hypothetical analogy of biological genesis and human knowledge thus becomes a singular genetic process through a consistent (and thought economical)

---

[40] “The self is no pot into which the blue and the ball just have to drop into so that a judgment [a blue ball] shall result. The self is *more* than a simple unity, and certainly no Herbertian *simplicity*. The same spatial elements, which close to a ball have to be blue and the blue has to be recognized as different from the places, as separable, in order to come to a judgment. [...] If we will see the self not as a monad isolated from the world, but a part of this world and in the midst of its flux, from which it came from and to which it is willing to diffuse again, so we will not anymore be inclined to see the world as something *unknowable*. We are then *close* enough to ourselves and *related* enough to the other parts of the world in order to hope for real *Erkenntnis*” (Mach 1905, p. 462).

[41] He is thus neither a nativist nor a blanc-slate empiricist, but close to modern notions of neuronal plasticity (for instance, by Buonomano and Merzenich 1998).

application of the idea of evolution. There is only biological and cultural evolution as two properties of the same genetic process. In this respect, Plato's conception of ideas is retained.

But then, another aspect of Plato's synthesis must be rejected as inconsistent with the idea of evolution. In the new evolutionary perspective, "forms" are not ideal anymore in an absolute, godly sense, just like species are not ideal, but temporary adaptations. Species as well as ideas are processes and products at the same time. In a Newtonian sense, they "interact over time" with the environment, or they are "reciprocal" as James suggested. Forms are only temporary *gestalts*, resulting from the way humans adapted biologically and culturally (historical genesis). These gestalts become adapted and transformed. They are never final.

From an *erkenntnis* theoretical view, and especially an *erkenntnis* psychological view, this fundamental conceptual change reciprocally requires many other conceptual changes which are based on this question. The empirical meanings of several foundational concepts, such as "knowledge" change, i.e. need to be adapted accordingly. Thus, the *erkenntnis* psychology of education fundamentally changes from the older Platonian/Aristotelian[42] view.

At the time of Mach, the Platonian/Aristotelian view had already been slowly eroded by central facts from various disciplines, which were obviously inconsistent with it. Many scientists (Erasmus Darwin, Spinoza, Herbart, Spencer, etc.) had already tried new syntheses from this, groping for new empirical meanings of concepts and new models regarding humans and nature. Charles Darwin's *Origin* was just a culmination of such efforts. Mach was afterwards the first[43] to develop a fundamentally new world view, including the (partial) synthesis from Charles Darwin and the facts from other sciences (physics, psychology, etc.). But he was unable to finalise (sufficiently stabilise) this view in all aspects during his lifetime.

Although Mach had a strong influence on science education (especially on the development of ideas of eminent scientists), he did not write a complete theory of science education. Thus, his intuition in science education remains more influential than his theory of it. His ideas have nevertheless been very fruitful (see Siemsen 2010a, b, c, d, 2011, 2012a, b). Therefore, an evaluation of the questions leading Mach to his ideas might have a strong effect on the future of science education. In science education, especially regarding the history and philosophy of science teaching, the time might now seem more recipient for his ideas than at Mach's own times.

---

[42] Aristotle as a student of Plato shared many of Plato's ideas; though as son of a physician, he was certainly more empirical in the physiological details of the theory.

[43] Mach published the first articles and books in this direction already four years (1863) after the publication of the *Origin*. This was much before Haeckel and Darwin himself wrote on the evolution of humans and human knowledge.

72.5 Mach's Central Ideas: Sensualism, Gestalt and *Erkenntnis* Theory

What are Mach's central ideas for science education? From his synthesis between the Platonian/Aristotelian world view and Darwin's world view, there are in principle three reciprocal areas of application: a consequent basis of all knowledge in its *sensual* origins, the thought-economical reduction of sensual elements to conceptual *gestalts* (*Vorstellungen*) and the *erkenntnis* theory, which provides the overall consistency of concepts as well as a meta- perspective and method for optimising one's own learning.

As Mach takes the psychophysical relations as basis for his world view, the sensual and physical perspectives provide the starting points for exploring this relation and therefore the empirical basis of all knowledge. Thus, in line with David Hume and contrary to the aversion of Plato and Aristotle towards sensuality, Mach postulates that the only possible (and empirical) grounds for concepts are the senses and sensual experiences. Reason and reflection are not something apart from this, some higher faculty of thought, but merely an extension and further development of sensualistic origins.[44]

When Aristotle postulates that "*no bodily activity* has any connexion with the *activity of reason*" (Aristotle 1930, p. 2068) and Plato urges to wait for the "opposing currents" of the senses to abate,[45] for Mach these seemingly "opposing [sensual] currents" (from an adult perspective) are the genetic origins of reason. Instead of Platonic waiting, one can encourage the thought-economical process right from its origins. Just because a suckling cannot speak words (i.e. "call names") does not imply that it cannot think or communicate. On the contrary, the suckling's speaking and reasoning are based on bodily activities. For Mach, there is only the "adaptation

---

[44] "Certainly one can judge internally, *without* linguistic expression or *before* it. […] One can easily observe this for clever dogs or children, who cannot yet speak" (Mach 1905, p. 112/113). "The basis of all knowing is therefore the *intuition*, which can be related to something sensually perceived, just vividly imagined or potentially imaginable, conceptualizable. The logical knowledge is just a special case of the formerly described, which is only concerned with the finding of consistency or inconsistency and which cannot be brought about without perception or imagination related to former findings. If we come to this new *finding* by pure physical or psychical chance or by planned extension of the experience by thought experiments […], it is always *this* finding, from which all knowledge [Erkenntnis] grows" (Mach 1905, p. 315).

[45] "… and by reason of all these affections [the "opposing currents" of nutrition and senses], the soul, when encased in a mortal body, now, as in the beginning, is first without intelligence; but when the flood of nutriment abates, and the courses of the soul, calming down, go their own way and become steadier as time goes on, then the several circles return to their natural form [mirroring the ideal thoughts of the Cosmos-god seen in the astronomical observations of circular movement], and their revolutions are corrected, and they call the same and the other by the right names, and make the possessor of them to become a rational being. And if these combine in him with any true nurture [Pythagorean dietary obligations] or education, he attains the fullness and health of the perfect man, and escapes the worst disease of all; but if he neglects education, he walks lame to the end of his life, and returns imperfect and good for nothing to the world below. This however, is a later stage […]" (Plato 1871/1892, Vol. III, p. 463).

of the thoughts to the facts and the thoughts to each other". But the adaptation of the thoughts to the facts must take priority as otherwise the thoughts have no relation to the world and are thus arbitrary. Furthermore, learning – including human learning – has evolved (according to Darwin) over millions of years from the sensual experience and not from some (relatively recent) metaphysical a priori system. Sensualistic learning must therefore be much more effective than rationalistic learning.

For Mach, reasoning is just a (cultural) result of the economy of thought. As one cannot memorise all singular sensual experiences, one needs to economise the thoughts on experience.[46] To describe the result of this process, Mach uses the concept of "gestalt".

72.6 Gestalt Psychology

Mach is known as the intellectual father of the gestalt[47] concept, which first Christian von Ehrenfels (1890) identified as a specific Machian concept. The gestalt psychologists (Wertheimer, Koehler, Koffka, Kaila, Lewin, etc.) developed Mach's gestalt concept into a full psychology (see, for instance, Ash 1995).

In his *Analysis*, Mach (1914, footnote p. 90) describes the origin of his idea of gestalt, which led to his last shift in world view.[48] "Some forty years ago […], in a society of physicists and physiologists, I proposed for discussion the question, why geometrically similar figures were also optically similar. I remember quite well the attitude taken with regard to this question, which was accounted not only superfluous, but even ludicrous. Nevertheless, I am now as strongly convinced as I was then that this question involves the whole problem of visual gestalts. That a problem cannot be solved which is not recognized as such is clear. In this non-recognition, however, is manifested, in my opinion, that one-sided mathematico-physical direction of thought […]".[49]

These ideas of Mach had intuitive influences on physics and mathematics but also on the development of psychology, for instance, on the concept of gestalt and

---

[46] Actually, nature economises memory in the sense of Hering (1870/1969). Therefore, gestalts are a plastic psychophysical process between physiological and cultural genesis, not limited to thoughts alone.

[47] The gestalt concept as a holistic concept was already used by Goethe or Herbart, but it did not have the genetic perspective. Only after Darwin, Mach could transform the concept into a "process and product". Therefore, seeing gestalt only as "holism", which one often finds in the literature, is an outdated, pre-Darwinian and in the sense of gestalt psychology inadequate understanding.

[48] There were at least two more shifts in his world view (see Mach 1914, p. 30). Mach had several such gestalt shifts in world view, but this shall not be of concern in this article. One nevertheless needs to be careful when reading Mach, which view he held at the time of writing. Some of the views are not consistent to each other.

[49] This quotation also bears reference to the prior-discussed question of methodological specialisation in science and the (unintended) intuitive training of one's thoughts.

gestalt psychology.[50] The article *On Gestalt Qualities* from 1890 by von Ehrenfels was regarded by Wertheimer and Koehler as the foundational article of gestalt psychology (see Wertheimer 1924, Koehler 1920/1938, and Ash 1995). In the beginning of this article, von Ehrenfels states that his ideas initiated from an intuition he had after reading Mach's *Analysis*:

> My starting point arose from several remarks and hints from E. Mach's "Contributions to the Analysis of Sensations" (Jena 1886) [...]. Mach sets up the, for some people certainly paradoxically sounding, hypothesis that we can immediately "sense" [*empfinden*] spatial patterns [*Gestalten*] and even "sound-patterns" or melodies. And indeed at least the second of these theses not only seemingly, but also from its contents should be undisputedly absurd,[51] if it would not be immediately intelligible, that "sensation" here is used in a different than the usual sense. [...] But if Mach, by using the term "spatial and tonal gestalts", also wanted to stress its simplicity, it becomes clear that he [...] viewed these "gestalts" not as mere combination of elements, but as something new (relative to the elements on which they base) and up to a certain degree independent. [...] I hope to be able to show in the following that Mach [in his reflections] has shown us the way of resolving the problem mentioned. (von Ehrenfels 1890, pp. 249–251)

The problem von Ehrenfels mentions is what William James called *The Knowing of Things Together* (1895).[52] If one takes a "regular" concept of sensation, it is a question of descriptive psychology. For Mach, it becomes a question of genetic psychology. What is "simple" might therefore appear to be simple in its current sensational gestalt but is actually a result of a "complex", i.e. reciprocal genetic process between sensation, physiology, memory and background. Gestalts are not linear (additive); they are adaptive and transformational.[53]

Abstraction therefore is not necessarily a "higher development", but a specialisation of thoughts. This specialisation might be thought economical in some contexts or hindering in others. What is "higher" and "lower" in a cultural sense cannot be judged anthropomorphically from the point of view of a specific culture.[54] Such categories often make no sense in anthropology, as the whole conceptual frames (world views) are different. All concepts might be based on completely

---

[50] His other influences, for instance, on the development of genetic psychology (Siemsen 2010b) and Boring (1950), shall not be of concern here.

[51] The German word used here is *widersinnig*, which literally translates as "counter sensual".

[52] Hadamard (1945, p. 65) quotes a description from Rodin: "Till the end of his task, it is necessary for [the sculptor] to maintain energetically, in the full light of his consciousness, his global idea, so as to reconduct unceasingly to it and closely connect with it the smallest details of his work. And this cannot be done without a severe strain of thought". The gestalt (statue) integrates the many details (ideas) into a *global idea*.

[53] Many gestalts are not best recognised in reality, but in caricatures, i.e. when certain properties are overemphasised, while others are neglected. Greek statues in the "classic" times are thus not just idealised bodies. They are idealised beyond the point a body could look like. Egyptian obelisks are not built straight, but slightly curved. Equally, "natural laws" cannot be observed in reality. They approximately describe many facts under idealised circumstances which can never be "achieved" for each single fact.

[54] Similar ideas have been developed by Franz Boas and have been very influential in US anthropological thinking until today (see Stocking 1968). On the closeness of the development of these ideas to Mach and their later influence on the initial ideas of Jerome Bruner, see Siemsen (2010b).

different sets of empirical meanings.[55] Also logic and our current Western concept of number came out of practical requirements and needs. They can thus neither be considered universal nor culturally independent. Because of the dominance of Western culture and the expansion of modern science, they have just been developed by more people over longer time than any other similar conceptual systems from other cultures.

The concept of gestalt also resolves the unproductive questions regarding the initial primacy of "nature or nurture". From a gestalt perspective it makes no sense to try to draw a triangle in one dimension and ask which of its sides has a larger share in its area. If one takes the concept of memory as a general function of evolution (see Hering 1870/1969), the problem disappears as a pseudoquestion.

72.7 Mach's *Erkenntnis* Theory in Science Education

The Machian world view is psychophysical, i.e. its basic "conceptual currency" of comparison (elements) requires switching between a physical and a psychical perspective. From the psychical perspective, the basic elements can be seen as sensual (defined recursively as gestalts). In a historical genesis process, clusters of sensual elements from different domains are synthesised into new gestalts, such as space, time and measurement. The syntheses in turn change the focus of attention to new observations, while neglecting others. Depending on the syntheses made, foundational empirical meanings of pre-scientific concepts are laid, which can help or hinder the acquisition of scientific concepts.

In order to keep all these processes consistent, to integrate them, one needs an *erkenntnis* theory. The *erkenntnis* theory provides the conceptual toolkit, the generality, but even more important the meta-method of consistently combining different methods of learning. It provides the observational meta-perspective on oneself as a learner so that one can optimise one's own learning, detect systematic errors, etc.

For implementing this in science education, Mach suggests, for instance, the use of history as (one) method, "[…] It should be shown in all analogous cases, how the concepts have originated historically, which observations have urged towards them. The most naïve historical exposition is always the best. The discoverer of a truth in natural science and the able student both stand before a new theorem without presuppositions. For both the same way is therefore most natural" (Mach 1876, p. 6). "The teacher using historical material […] will not run into the danger of expecting from the student to understand in one attempt, what could develop in the most

---

[55] The difference in observed facts can be so intuitively fundamental that even with long training, one cannot observe them in principle. For instance, Boas observed that he consistently heard phoneme in Inuit language one time as one sound, another time as a different sound. His interpretation was that psychophysically, the factual sound gestalt was in between, but impossible for him to hear in the way the natives would hear it.

important heads but slowly and gradually" (Mach 1876, p. 6/7).[56] "The historical exposition will lead to the comparison of different chapters and thereby separate the fundamental from the accidental and conventional" (Mach 1876, p. 8). "The historical [genetic] exposition will apart from clarity have the advantage that the teaching stops to be dogmatic. Science appears as something evolving, not finished, still to be shapable in the future. Mental educability instead of simple education should be the result of such a teaching" (Mach 1876, p. 9). The use of history for Mach thus mainly serves an *erkenntnis* theoretical function.

Mach elaborates the idea of how to teach in a way to optimise the learning for science education: "[…] The formal education is a seed, which by itself will develop fruitfully. This process is not to be underestimated relative to the positive skills, when the student immediately transfers to the practical life, because then he can easily acquire what is missing by himself. On the other hand, an unnecessarily stuffed head cannot help to lead him in times of need out of the critical situation. Formal education is on the other hand the main goal if the teaching is continued in higher education. Then all elements have to be transformed anyway and have to be taken as material and foundation of the new. It is therefore practical to limit the subject matter as far as possible, but work on it in a *many-sided way*. Only by dealing differently with the same issue, one understands the basis of the method and achieves ability in its usage" (Mach 1876, p. 1/2).

The genetic method is thereby different from the axiomatic method, which starts from basic axioms; it is different from the Socratic method, which starts from (linguistic) definitions (already presupposing a frame or a "background", see Rubin 1921), but as described before, it is also not simply historical, though it makes intensive use of history. "One can certainly provide the student with a broader knowledge by starting from ready-made definitions and concepts, placing ready-made doctrines in front of him and proving them. This method is not even so bad in mathematics, because there the step from the experience [*blosse Anschauung*] to the definition and to the theorem might be very short and can therefore be complemented by each able student. The physical knowledge which is acquired in this way nevertheless always appears as externally imposed. Especially for the student who reflects, sudden gaps of clarity will appear which he will not be able to resolve, if he does not know, how one has arrived at the concepts put at the top" (Mach 1876, p. 2/3).

One way of implementing this is by letting the students guess the "success" of an experiment before it is conducted. "Not only thereby the attention is increased, but youths will from the errors which occur in this also draw the lesson that natural laws cannot be philosophized-forth [*lassen sich nicht herausphilosophieren*]. A body does not, as most will guess, in double the time also fall double the way. The pendulum of fourfold length does not also show the fourfold duration of oscillation. One here does not have to construct *a priory*, but to observe" (Mach 1876, p. 20/21).

72.8 Mach's Successors

The successors of Mach, who had Machian effects in their teaching, are William James, Alfred Binet, Eino Kaila, Kaarle Kurki-Suonio, Karl Hayo Siemsen, Martin ernohorský, Rudolf Laemmel, Eugenie Schwarzwald, Frank Oppenheimer, Alexander Israel Wittenberg, Max Wertheimer, Abraham S. Luchins, Adolf Hohenester and John Bradley.

There are several people who used at least part of Mach's teaching ideas in their teaching philosophy, but probably not enough to produce the exponential effects (though this has not been studied in all detail in every case): John Dewey, Otto Blueh, Jerome Bruner, Benchara Branford, Catharina Stern, Eric M. Rogers, Peter Drucker, Paul A. Samuelson, Wilhelm Ostwald, Henry Edward Armstrong, Edgar W. Jenkins, Martin Wagenschein, Georg Kerschensteiner, Spiru Haret, Efraim Fischbein, Solomon Marcus, Joachim Thiele, Robert Wichard Pohl, Walter Jung, Fritz Siemsen, Hugo Kükelhaus, Hans Freudenthal, George Sarton, Alfred N. Whitehead, James Conant, Gerald Holton, Frank Wilczek, K. V. Laurikainen, Edouard Claparède, Théodore Flournoy and Jean Piaget. Many more educators have been inspired by Machian ideas; though after several generations, these "mother's milk" effects become increasingly difficult to trace and to make explicit.

[57] The other PISA studies are equally interesting, but will not be cited, as the general issues discussed here can be taken from any single one of them

Hayo Siemsen is working on his habilitation on Mach's influences and his ideas on the philosophy of education and the psychology of research. He is also member of the Ernst Mach Institute for Philosophy of Science and member of the newly founded international Institute for Processes of Learning. His Ph.D. theses were focused on innovation systems, especially on the question if one can learn to be innovative. In various publications he covered a wide range of areas, including education, psychology, economics, management, history, methodology and philosophy/*erkenntnis* psychology of mathematics. The publications are following Mach's general ideas and broad influences rather than scientific categorisations. Recently he published a series of articles in *Science & Education* on Machian education, especially in Finland in comparison with other, similar science education.

Chapter 73
Frederick W. Westaway and Science Education: An Endless Quest

William H. Brock and Edgar W. Jenkins

73.1 Introduction

> I fear that during my professional career, I advocated the claims of science teaching much too strongly, and I am now quite sure that the time often devoted … to laboratory practice, and to the purely mathematical side of science, more especially chemistry and physics, was far too great. (Westaway 1942a, p.v)[1]

So wrote F. W. Westaway, teacher, headmaster, His Majesty's Inspector (HMI) and eloquent advocate of science education, in the preface of his last book, published in 1942, with the intriguing title *Science in the Dock: Guilty or Not Guilty?* Who was Westaway, what influence did he have upon school science teaching and what had prompted him to raise and address this question?

Frederick William Westaway was born on 29 July 1864 at Cheltenham, Gloucestershire, the first of seven children of William and Caroline Westaway, three of whom died in infancy. It seems clear that the family circumstances were extremely modest. His father was a travelling blacksmith, and his mother (to judge from the mark she made on Frederick's birth certificate) was unable to write. Westaway later recalled receiving his first chemistry lesson at the age of 10 in 1874. It was given by the Gloucester Public Analyst[2]:

---

[1] The preface was dated September 1941. He had expressed similar doubts following WW1 in a new preface to the 2nd ed. of Westaway (1919, p. xii).

[2] Probably John Horsley, a founder member of the Society of Public Analysts in July 1874. He specialised in the analysis of milk and dairy products. Westaway joined the Chemical Society in June 1892.

> There was no laboratory available, but there was a well-fitted lecture room, and in later lessons a few gases were prepared. But the first lesson, which extended over an hour, was frankly a lecture on the atomic theory. No experiments whatever were performed, but the formulae and equations which covered the blackboard impressed at least one small boy. (Westaway 1937a, p. 490; Westaway 1929, p. 18)

By 1881 the family had moved to Ruardean in Gloucestershire's Forest of Dean, where Frederick's father was landlord of a public house.[3] By then Frederick was a pupil teacher at the village school from where he enrolled at St John's Training College in Battersea and began his formal teaching career in London in 1886 (Westaway 1929, p. 19). Concerning this experience, he provides a personal anecdote of some historical interest. He was allocated two hours for chemistry and two hours for mechanics.[4] He had no laboratory or demonstration bench and only a balance that he had made himself. The Bunsen burner had to be fed from the gas pendant above the pupils' heads. Using Ira Remsen's revolutionary American textbook, he proceeded to teach (Remsen 1886):

> In the middle of a lesson on equivalents, two visitors whose names I did not catch were shown in, and they sat down and listened. When I had finished they came up and showed what I thought to be a surprising appreciation of what I had been doing, and eventually one of them said: "Do you happen to know Roscoe's book on chemistry?" "Yes," I replied, "and a thoroughly unsatisfactory book it is. The writer makes unjustifiable assumptions about chemical theory before he had established necessary facts. It is the kind of thing that no teacher ought to do." At this stage the second visitor interposed and said, "I think, perhaps, you are asking for trouble. Let me introduce you to Professor [afterwards Sir Henry] Roscoe." However, in spite of the criticized book, I learnt more about the teaching of chemistry in the next quarter of an hour than I might have learnt in the next ten years. In particular, I learnt a much needed lesson – that there is more than one avenue of approach to the teaching of science, and that it is sheer folly to assume that science must be taught according to one pedagogue's prescription. (Westaway 1929, pp. 19–20)[5]

He lodged in Lambeth, joined the rifle volunteer movement, passed his London Matriculation examination in 1887 and graduated BA from the University of London in 1890. It was a career path followed by a significant number of the more able pupil teachers in the last two decades of the nineteenth century, and many of them found employment in the growing number of post-elementary schools, known as Higher Grade Schools, established by the School Boards in larger towns and cities (Vlaeminke 2000). From hints in his later books, it appears that Westaway continued his self-improvement by attending evening classes and the summer schools for science teachers that were run by Frankland (chemistry), Guthrie (physics) and Huxley (biology) at South Kensington under the auspices of the Department of Science and Art (DSA).

---

[3] Later, between 1897 and 1901, William Westaway was landlord of the George Inn, Market Street, Gloucester.

[4] This may imply that the bulk of his timetable was spent in teaching more general subjects such as English and Latin.

[5] For Roscoe's textbook, ironically published in the same Macmillan's Primer Series as Remsen's book, see Roscoe (1866; new ed. 1886). The other visitor was the chemist and educationist John Hall Gladstone, as revealed in Westaway (1936, p. 313).

In May 1892, when teaching at a school at Stockwell in south-west London, Westaway married Mary Jane Collar, the daughter of a pianoforte maker and herself a teacher.[6] Her two brothers, George and Henry, were also teachers, and both eventually became headmasters of London schools. The newly married couple immediately moved to Dalton in Furness[7] where he had been appointed headmaster of the Higher Grade School, the local Board School having been established in 1878. Westaway thereby began his formal connection with South Kensington since the school would have been recognised as an organised science school for the purposes of DSA grants. The chief local industries were iron ore mining and quarrying, and the School Board, like that in other northern towns in England, recognised the need for a better-informed and technically competent workforce. It is alleged that Westaway grew a beard to hide his relative youth. Their only child, Katherine Mary, was born in the School House in 1893, and her father was to exert an important influence upon her upbringing and career. She eventually became a distinguished classical scholar and an outstanding headmistress of Bedford High School from 1924 until her retirement in 1949.

Clearly ambitious, Westaway moved from Dalton in Furness to Bristol in 1894 to become headmaster of the newly built St George's Secondary and Technical School which contained "a thoroughly well-appointed Chemistry Laboratory, a large Science Lecture Room, a Workshop, a Dining Room and accommodation of every kind conducive to the well-being of the scholars".[8] Its finances were entirely contingent upon the school's ability to earn grants by Westaway's pupils gaining high passes in the examinations run by the DSA. A local newspaper reported:

> The [School] Board considered a number of applications for the appointment of the St George Higher Grade School. Mr *F. W. Westaway*, at present holding an appointment at the higher grade schools, Dalton-in-Furness, was appointed unanimously. In his application his University distinction was stated to be (a) B.A. London; Inter B.Sc., final examination, deferred until 1895; (c) Member of Convocation of the University of London. The list of qualifications, particulars of past experience, copies of testimonials, and prospectus of present school were considered by the Board highly satisfactory. (Anon 11 October 1894)[9]

Vlaeminke's study of the school's logbooks reveals that Westaway taught all the science and mathematics himself and triumphantly gained passes for his pupils in the DSA examinations that were the best in the Bristol area. No doubt this was

---

[6] The ceremony was conducted at St Matthew's Church, West Kensington (Mary Collar's parish), by Edwin Hobson, the principal and chaplain of St Katherine's College, Tottenham, where Mary had trained to be a teacher. The college, which had been set up originally by the Society for the Promotion of Christian Knowledge in 1878, is now part of Middlesex University. Hobson had been vice-principal of St John's College, Battersea, from 1874 to 1877 before Westaway was a student there.

[7] Dalton in Furness lies on the southern edge of the Lake District in Cumbria (until 1974 in Lancashire). It is famed for its castle and for Furness Abbey. The school, which opened in 1877, survives as an infant school.

[8] This was Bristol's first state secondary school created by local entrepreneurs in 1894. Its premises, which are currently used as a Sikh temple, were opened in 1894. Following various changes of name, it moved to new premises in 2005 as St George City Academy.

[9] The school's development is analysed in Vlaeminke (2000).

noticed by the Department of Science and Art for, within a year, Westaway was offered a subinspectorship in the department. On the face of it, accepting this offer was an odd decision, for although the character of the DSA was changing during the 1890s, the task of its inspectors largely remained one of ensuring that its militaristic rules and regulations for the conduct of examinations and payment by results were strictly adhered to (Butterworth 1982, pp. 27–44). The appointment to the inspectorate probably involved a drop in salary, though this would have been compensated by the prospect of a very good pension.[10]

Westaway's movements between 1895 and the passing of the (Secondary) Education Act of 1902 are unclear. He was undoubtedly not content to sit on his laurels but continued his studies at the Royal College of Science at South Kensington in London where he was a prizeman in mathematics and physics. By 1901, however, his post in the civil service had become that of one of Her Majesty's Inspectors of Education with responsibilities for secondary education in the area of Essex.[11] It was here that their daughter Katherine, together with two friends, began her first lessons with a governess (Kitchener 1981; Hunt 2004), and Westaway cultivated a friendship with R. J. Strutt, 3rd Baron Rayleigh, who kept a private laboratory at his home at Terling Place, near Chelmsford. Within a year, however, Westaway took over responsibilities for inspection in the Bedfordshire area. The family moved to Pemberley Crescent in Bedford, close to Bedford School.[12] He remained an HMI until his retirement in 1929, when he moved to the village of Aspley Heath, adjacent to Woburn Sands in Bedfordshire. He was intensely proud of his profession and of the intellectual attainments of the colleagues with whom he mixed. He sometimes indulges in name-dropping: for example, when mentioning the Irish physicist Thomas Preston (1860–1900), he refers to him as "for some time an esteemed colleague of the present writer's" (Westaway 1937a, p. 364).[13] Preston did, indeed, combine his chair of natural philosophy at Trinity College Dublin with a government post as an inspector of science and art for Irish schools, but it seems unlikely that Preston ever came into direct contact with Westaway.

73.2 The Philosophy of Science

During his long life, Westaway authored some sixteen books, many of which ran into several editions, although not all were concerned with science education. His first book, *Scientific Method: Its Philosophy and Practice*, was published in 1912.

---

[10] On the recruitment of inspectors, see Gosden (1966, p. 25).

[11] The 1870 Education Act abolished the denominational character of the inspectorate and reorganised HMIs territorially to reduce their travel. This system continued after the reorganisation of secondary education following the Education Act of 1902. See Gosden (1966, pp. 27 and 111). The Westaway family moved from Bristol to 87 Camden Villa, Fuller's Road, Woodford, Essex.

[12] According to 1901 and 1911 Census data, the Westaways employed one servant girl.

[13] For Preston, see Weaire and O'Connor (1987).

The date is significant since it coincides with the growing scholarly interest in the history and philosophy of science, evident, for example, in the first publication of the journal *ISIS* by George Sarton in Belgium in 1913. Westaway dedicated his book to the physicist Lord Rayleigh (1842–1919) "to whose work and whose teaching the author is deeply indebted" (Westaway 1912, p. 439).[14] The first edition of *Scientific Method* was in four parts. The first examined philosophical issues and offered a commentary upon the ideas of a range of philosophers including Plato, Aristotle, Francis Bacon, Descartes, Locke and Hume. This was followed by attention to Victorian "methodologists" such as Whewell, Mill and Herschel and a discussion of what might be meant by such terms as induction, deduction, scientific law and hypothesis. The third part of the book turned to the history of science and was devoted to "Famous men of science and their methods". In this section, scientists such as Harvey, Newton, Black, Priestley, Faraday, Wallace, Darwin, Clerk Maxwell, Ostwald and J. J. Thomson were largely allowed to speak for themselves through the form of generous quotations. The book ended with a practical section for science teachers entitled "Scientific method in the classroom" in which Westaway offered examples, drawn from botany, chemistry and physics, of what today would be called teaching by investigation.

Nature thought the book is "a model of clearness" and ideal for both science teachers and the general reader. Its sole fault, if any, was the use of excessive quotations, though the reviewer put this down to the fact that Westaway was exceptionally well read (JAH 1912).[15] The reviewer missed the fact that Westaway was concerned with more than promoting a greater understanding of the history and philosophy of science. As he made clear in his preface, he was anxious to bring humanists and realists (i.e. scientists) closer together and to reconcile the ideals which they represented. The need for such reconciliation was to become particularly urgent during the First World War when something of a battle of the books broke out between the scientific community and those representing the humanities, over the contribution that science could make to liberal education.[16] One outcome was the claim, already promoted in Westaway's book, that the history and philosophy of science offered a means of humanising a narrow, specialised and otherwise dehumanising scientific education.

The second edition was published immediately after the war had concluded in 1919. A new preface blamed Britain's industrial problems on its "continued use of haphazard methods". It would be the undoing of the nation if this were continued:

---

[14] Also Westaway (1919, 2nd ed., p. 426), Westaway (1924, 3rd ed.), Westaway (1931b, 4th ed. "revised and enlarged, present-day methods critically considered") and Westaway (1937a, 5th ed.). Most of these editions are available online. According to the *World Catalogue,* Chinese translations were made in 1935 and 1969.

[15] The reviewer was probably the chemical physicist John Alexander Harker.

[16] There is a large literature on the theme of humanising the science curriculum. See Jenkins (1979, pp. 54–55), Brock (1996, Chap. 19), Mayer (1997), Donnelly (2002, 2004) and Donnelly and Ryder (2011).

> On the one side we have Germany, clear-headed and thorough; America, original and enterprising; Japan, self-denying and observant; France, pain-staking and clever: all four nations believers in *work*. On the other side we have Britain, insular and unsystematic, looking upon work as a nuisance because interfering with pleasures. (Westaway 1919, p. xii)

An appendix, "Retrospect and Reflections 1912–1918", continued this theme, going so far as to assert that Britain had not won the war because of science or education but because of the reawakening of the nation's dormant national qualities. For their part, the Germans had lost because of their servility to authority and inability to think for themselves. Westaway's solution, overtly political, involved the redistribution of wealth and the wholesale application of scientific method. The "Retrospect" surveyed the functions and influence of science and scientific method on national life. This time the *Nature* reviewer, noting how the Thomson Report on Natural Science Teaching had urged science teachers to become acquainted with the history and philosophy of science, recommended the volume enthusiastically as enlightening and helpful. "Clearly presented" with "apt and instructive" examples, "any science teacher, whether at university of school, who reads the book, cannot fail to derive profit and interest from it" (Anon 1920a).[17]

By the time the 4th "revised and enlarged" edition had appeared in 1931 (a third edition in 1924 merely expanded the chapter on the theory of relativity), Westaway was a lot more sanguine about Britain's future. Post-war society, he suggested, had become less rule of thumb, more rational and systematic. He expressed delight in the progress of mass production with its implicit inclusion of specialisation, expertise and machinery in the operations of industry. Even so, there was still need for "the development of the scientific study and impartial examination of all the complex factors, economic, social, political, and racial, involved in controversial problems which are the sources of international friction" (Westaway 1931b, p. xii). Westaway clearly believed that the revised version of his book would help teachers produce a workforce geared to a mass-production society. To that end, he added a fourth section on present-day methods in contemporary science – including nuclear physics and quantum mechanics – and a fifth section on how scientific method could be inculcated in the classroom and lecture theatre.

In the final edition, published well into his retirement in 1937 and which received a Chinese translation, two further sections were added: one giving excerpts from the writings of "distinguished workers of the day" whom he obviously admired[18] the other offering further examples of the application of scientific methods for advanced students (Westaway 1937a). This extraordinary section included the analysis of historical facts using the example of the causes of the decline and fall of the Roman Empire, as well as an open-ended discussion of whether there was a criterion of excellence in aesthetics – a subject that he was to expand in another book.

---

[17] The unsigned review was probably by the editor, Richard Gregory, whose much reprinted book *Discovery* (Gregory 1916) was admired by Westaway.

[18] These included Max Born, Herbert Dingle, Julian Huxley, James Jeans, Hyman Levy, Max Planck and Walther de Sitter.

73.3 Science Teaching

Westaway had included a short section on scientific method applied in the classroom in *Scientific Method* in 1912 and the subsequent editions, but it was not until his retirement that he expanded it as a separate book in 1929. Dedicated to his friend and superior in the inspectorate, Francis B Stead, *Science Teaching: What It Was, What It Is, What It Might Be* was a volume that sought to assert the liberal values of a scientific education, providing always that science was well taught. From this perspective, *Science Teaching* follows the tradition of earlier works by Mach (1893) and Dewey (1900, 1902, 1916),[19] a tradition that was to be sustained in subsequent years by the writings of Schwab (1982), Conant (1947, 1957), Holton (1952) and many others. It also owes something, and not simply as far as its title is concerned, to Edmond Holmes' seminal volume, published in 1911, *What Is and What Might Be* (Holmes 1911),[20] and to Stead's work as secretary (and compiler) of J. J. Thomson's influential wartime report on *Natural Science in Education* (Stead 1918).[21] Drawing upon his experience as an HMI – he speaks of witnessing "1000 lessons a year for over 30 years" (Westaway 1929, p. xii) – Westaway argues in *Science Teaching* for a broadening of school science education to include some biology, astronomy and palaeontology and sets out the case for making science a compulsory part of the school curriculum. But the book is more than this. It is also a primer of practice and a challenge to those whose educational "claims on behalf of science … are sometimes tinged with a good deal of arrogance and intolerance, and whose advocacy is thus better calculated to make enemies than enlist friends" (Westaway 1942b, back cover).[22] Once again, Westaway is seeking to promote a middle way in education, one in which there is "no natural antagonism between science on the one hand and humanism on the other" and one in which the history and philosophy of science play a key part. Such an ethos was shared with another significant HMI, the historian and positivist, Francis Sydney Marvin (1863–1943).[23]

---

[19] Mach (1893) first appeared in German in 1883. It remained in print throughout Westaway's career. Westaway frequently cited and recommended Mach in his writings, but not Dewey.

[20] Holmes (1850–1936), who became chief inspector of elementary schools in 1905, resigned in 1911 over criticisms of HMIs who had formerly been elementary schoolteachers. See Gordon (1978) and Shute (1998).

[21] Chaired by the physicist J. J. Thomson, the report was actually compiled by the committee's secretary, Francis Bernard Stead (1873–1955), H. M. chief inspector of secondary schools and a close friend of the Westaways. Stead, a Cambridge NST graduate, had worked at Plymouth's Marine Biology Association and Clifton College before joining the inspectorate in 1908. The science report was one of four (science, classics, English, modern languages) eventually prepared by the Board of Education. See *Nature* 175 (1955), pp. 148, 175) and Jenkins (1973, pp. 76–87).

[22] A 4-page publisher's pamphlet of "press appreciations" (c. 1930) in the possession of WHB carries the quotation from *Journal of Education*: "Get the book and read it; it is the best thing yet".

[23] Marvin, August Comte's principal spokesman for positivism in Britain, was an HMI from 1890 to 1924. He played a major role in improving the teaching of history in schools. See Mayer (2004). Curiously, despite his influence on the teaching of history, Marvin has not been included in the *Oxford DNB,* whereas his wife, Edith Mary Marvin (née Deverell) (1872–1958), a fellow HMI,

Westaway's definition of a successful science teacher (ignoring his gender bias) may be demanding and an ideal, but it still suggests what is required in the profession:

> He knows his own special subject through and through, he is widely read in other branches of science, he knows how to teach, he knows how to teach science, he is able to express himself lucidly, he is skilful in manipulation, he is resourceful both at the demonstration table and in the laboratory, he is a logician to his finger-tips, he is something of a philosopher, and he is so far an historian that he can sit down with a crowd of boys and talk to them about personal equations, the lives, and the work of such geniuses as Galileo, Newton, Faraday, and Darwin. More than all of this, he is an enthusiast, full of faith in his own particular work. (Westaway 1929, p. 3)

Little wonder that he admitted that he thought a teacher was not really fully equipped to teach effectively until he was in his thirties.

Science Teaching, with its extensive syllabus suggestions and advice on laboratory accommodation and equipment, as well as its helpful discussion of classroom practice, was well received by the reviewers ("a book of outstanding usefulness", "remarkable, critical and stimulating"), and it became a staple of initial training courses for graduate science teachers.[24] His suggestions that the periodic law and wave motion (not energy) should be the pole stars of the school chemistry and physics syllabuses were undoubtedly influential, as was his emphatic insistence on the introduction of biology into the secondary curriculum. Like the rest of Westaway's books, it is characterised by a directness and lucidity of style and by the author's capacity to engage with a wide range of disciplines and to draw his arguments and examples accordingly. The book was reprinted in its year of publication and again in 1934, 1942 and posthumously in 1947. Even today, much of Westaway's advice to those learning to teach science has the ring of experience. Some of his questions for young science teachers or pupils leaving school remain both challenging and of interest. For example,

> Do you consider that the estimates of stellar distances and electronic magnitudes correspond approximately with actual fact? What part of the available evidence is experimental and what part is inferential? Is the latter evidence convincing?
>
> How would you estimate the number of flaps made in a second by the wings of a flying bluebottle?
>
> Some years ago a science teacher, working single handed, was trying to extinguish the burning woodwork (pitch-pine) of a fume cupboard … when he was called to a boy who had become unconscious through the inhalation of chlorine. How would you have coped with the double emergency?

Further insights into Westaway's views on science teaching are revealed by an appreciation he wrote for *The School Science Review* of Henry Edward Armstrong, following the death of the latter in July 1937. Westaway had come into contact with both Armstrong and Thomas Henry Huxley as early as the 1880s while studying at

---

has. The same has happened with Westaway and his daughter, Katherine. Both Marvin and Westaway are to be included in a forthcoming update of *ODNB*.

[24] For an appreciative review by the science teacher and historian of science, Eric Holmyard, see Holmyard (1929). Note also the appreciation of the Latymer School science teacher George Fowles (1937, pp. 13, 501, 513, 527).

the Royal College of Science, and he thus constitutes a direct link with some of the leading figures in the late nineteenth-century education.[25] It is clear from Westaway's *Science Teaching* that it was Huxley who exercised the greatest influence upon his ideas, and he was intensely proud to have been personally examined by Huxley in biology. For Westaway, the purpose of a scientific education was the making of Huxley's "cold logic engine", in which "the desire for discriminating evidence" would become a "predominating factor" in thinking.[26] Nonetheless, he found Armstrong's heurism, with its commitment to teaching "scientific method", an approach to science teaching in which "practice simply would not yield to precept" (Westaway 1929, pp. 20–27).[27] The imparting of information was a vital function of teaching, and this was the cardinal fault of heurism in its pure form. Moreover, heurism was "not new" but, in essence, a strategy "used by intelligent teachers all down the ages". For Westaway, therefore, Armstrong's great contribution to science education was not heurism itself but the fact that he compelled others to keep their "defensive weapons keen and bright" and be "ever ready to defend alternative methods". Armstrong, he thought, had given hostage to fortune by calling his system the heuristic method instead of, say, "the search" or "discovery method" (Westaway 1929, p. 20). However, he admired Armstrong as a teacher and had high praise for his account of chemistry in the 13th edition of *Encyclopaedia Britannica* (1926) for the way it cast light on the inner nature of chemistry.

73.4 Mathematics Teaching

It would seem that Westaway's first love as a practising teacher was mathematics. In several places, he lamented the loss of Euclid due to the efforts of the former Association for the Improvement of Geometrical Teaching. Nevertheless, he became a keen member of its successor, the Mathematical Association, and a regular reader of its *Mathematical Gazette* (Price 1994). He published two geometry textbooks for private and state secondary schools and technical colleges which differed only in that the latter contained additional material for middle-form boys up to the age of 14 (Westaway 1928a, b).[28] The texts were addressed directly to both teachers and

---

[25] "Faith in my own old teachers –Thomas Henry Huxley, John Tyndall, John Hall Gladstone, and (the 3rd) Lord Rayleigh – is as strong as ever, all of whom, in season and out of season, insisted on laboratory and field work first and always, on *facts* and ever more facts" (Westaway 1936, pp. ix, 359, and 745). He also recalled the wonderful lecture demonstrations of Charles Vernon Boys in Westaway (1936, pp. 692).

[26] Westaway was quoting from Huxley (1905, pp. 76–110).

[27] See Brock (1973; reprint 2012).

[28] Westaway (1928a) covered the geometry syllabus from age 8 to 13 when the common entrance examination for admission to a public school was taken. Westaway (1928b) must have been published a few months after the other geometry textbook. Both texts mentioned Westaway's admiration for the geometry lessons of his "friends" Frederick William Sanderson (1857–1922), headmaster of Oundle School, and Edward Mann Langley (1851–1933), a teacher at Bedford Modern School and founder-editor of *The Mathematical Gazette.*

pupils, the latter being expected to read a chapter before it was discussed with them. In line with contemporary feelings about geometry teaching, Westaway avoided deductive proofs from first principles. Long chains of reasoning were also avoided, and intuitive reasoning was frequently used, while practical examples from surveying and carpentry demonstrated the practical significance of geometrical reasoning.[29] Typically, Westaway supplied a list of Latin words and the mathematical expressions derived from them in the expectation that teachers and pupils would correlate their mathematical and classical learning.

In 1931, following the tremendous success of his book on *Science Teaching*, Westaway's publishers suggested that a similar book addressed to mathematics teachers was a desideratum. The result was another remarkable handbook offering young inexperienced teachers advice and useful hints on putting mathematics across in the classroom (Westaway 1931a). Although entitled *elementary* mathematics education, the 28 chapters in fact ranged from simple addition and subtraction to teaching the calculus and thus covered the whole of school mathematics from the level of infants to university entrants. As one reviewer remarked (Anon 1931), Westaway's standard for what a pupil should know was very high, citing as evidence the casual remark that a 4th-form boy was apt to forget the factors of $a^4 + 2a^2b^2 + b^4$ [i.e. $(a^2 + b^2)^2$]. (Was this a reflection of a decline in expectations or merely due to the fact that Westaway's treatment smacked of the nineteenth, rather than, the twentieth century, as the same reviewer suspected?) There were also sections on mathematics in astronomy and biology (a field Westaway foresaw as developing in significance), time and the calendar (which he thought was the job of mathematics staff to teach), as well as on non-Euclidean geometry and the history and philosophy of mathematics. Westaway specifically addressed *new* teachers rather than experienced accomplished instructors, thus ensuring, like his treatise on science teaching, the book's heavy use in British teacher training colleges and ready sale among tyros. Its valuable suggestions for organising the math curriculum throughout a school must also have recommended it to senior staff as well. Curiously, and surprisingly, the Mathematical Association ignored the book, though it was reviewed favourably and at length by the Harvard geometer Ralph Beatley who recognised that many of the problems delineated by Westaway were common in America as well (Beatley 1933).

73.5 Language Teaching

Westaway had clearly taught Latin at an early stage of his career and had a deep respect for classical education.[30] Although we think of him primarily as a science educator, he also made an informative contribution to classical teaching in the form of his second book *Quantity and Accent in the Pronunciation of Latin*, which he

---

[29] This practical aspect was praised by Dobbs (1929).

[30] His love of the classics was inherited by his daughter Kathleen who lectured in classics at Royal Holloway College (1920–1924) before becoming headmistress of her old school. See Westaway K. W. (1917, 1922, 1924).

published in 1914 (Westaway 1914).[31] Westaway was adamant that it was not a textbook and that it was not aimed at schoolteachers. His targets were private students of Latin and those whose knowledge of the rules of pronunciation was rusty. The context was a contemporary debate between an older generation of classicists who wanted to continue using an Anglicised "easy-going" form of pronunciation and the younger generation of classicists whose knowledge was informed by research in philology and phonetics. "Mr Westaway's heart is in the right place", that of a reformer, concluded Edward Adolf Sonnenschein, the professor of Greek and Latin at the University of Birmingham, and "he writes with conviction" (Sonnenschein 1914, pp. 213–214). That the text did well in modernising the teaching of Latin is suggested by the fact that it remained in print in the 1920s and that an enlarged edition appeared in 1930. The text had been read with approval by both John Percival Postgate (1853–1926), professor of Latin at the University of Liverpool and the founder (with Sonnenschein) of the Classical Association in 1903, and Westaway's superior in the Education Department John William Mackail (1859–1945), an eminent Virgil scholar. Westaway became a life member of both the Classical Association and the Modern Languages Association in 1903. Like the British Association for the Advancement of Science, which he also joined in 1903, Westaway must have seen these organisations as a valuable way for an HMI to keep up to date.

In *Scientific Method*, Westaway's concern for logical thinking took him into one of his many other interests, language and clarity of thought and expression, and hence into the use of words to express causality. It seems he regarded English grammar as offering important philosophical insights for the science teacher. In his inspections of schools and technical colleges, not unexpectedly, Westaway came across poorly expressed written reports of experiments. More surprisingly, he came across ungrammatical and illogical prose in reports by scientists in periodicals such as *Nature*, which he evidently read each week. Another periodical he read regularly, but never contributed to, was the *Mathematical Gazette* which had been founded by the Mathematical Association in 1894. Westaway joined the association in 1914. He was impressed and inspired by his chief in the inspectorate, W. C. Fletcher, who published an article in the *Gazette* in March 1924 stressing that mathematicians should write good prose between their symbols (Fletcher 1924).[32] Fletcher's essay, together with the earlier appearance of George Sampson's influential report on the teaching of English in 1921 (Sampson 1921),[33] probably inspired Westaway to publish *The Writing of Clear English* in 1926. While significantly subtitled *A Book*

---

[31] This was the only one of his books not published by Blackie. Note also Westaway (1933a).

[32] Fletcher (1865–1959) is best known for "Fletcher's trolley", an improvement on Atwood's machine for teaching mechanics. After graduating from Cambridge as 2nd wrangler in 1887, Fletcher taught at Bedford School (1887–1896) before becoming headmaster of the Liverpool Institute (1896–1904). He was appointed Chief Inspector of Secondary Schools in 1904. He retired in 1926 only to teach at the girls' school where his daughter was headmistress. See obituary (Anon 1959).

[33] Sampson (1873–1950) followed a similar path to Westaway – pupil teacher, London Matric, teacher, headmaster, district inspector for London County Council.

for Students of Science and Technology, its clear exposition of the principles of English grammar and advice on sentence and paragraph construction and logical writing style would have made it useful to a generally educated readership that found itself in need of English improvement (Westaway 1926).[34] In retirement, Westaway revised and enlarged the book as *The Teaching of English Grammar Function versus Form* (Westaway 1933b).[35]

In 1932 Westaway persuaded his publishers to launch a series of books offering instruction and advice to teachers under the umbrella title of The Teachers' Library. Although Westaway did not write a book specifically for the series, he recruited the help of other HMIs and acted as the advisory editor for the series. The library was planned "for the guidance of teachers whose daily work is concerned with children of eight and upwards" (Finch & Kimmins 1932, Preface).[36]

73.6 History of Science

As we have seen from both his *Scientific Method* and *Science Teaching*, Westaway believed that teachers should tell stories about great mathematicians and scientists. He also thought sixth-form students should be encouraged and challenged to read, among other original works, Newton's *Opticks*, Faraday's *Researches on Electricity* and Darwin's *Earthworms* (Westaway 1929, p. 383). The interwar years were a particularly productive time for Westaway. In addition to books on the teaching of mathematics, geometry and English (for science specialists), he wrote a large volume of over 1,000 pages entitled *The Endless Quest: Three Thousand Years of Science* (Westaway 1934).[37] This huge, richly illustrated volume is something of a tour de force, and, even today, when specialised degree courses are available in history of science, as a history of science published in 1934, it makes appealing and, in places, challenging reading. Westaway's originality is shown in his deliberate attempt to write a critical appraisal of scientific development and to show its weaknesses as well as its strengths. He acknowledged the influence of his departmental colleague, the positivist historian Sydney Marvin, who was a friend of George Sarton and who was keen to see history of science taught by history teachers. An anonymous reviewer in *The School Science Review* described the book as "a veritable encyclopaedia of science", adding that only "a writer of extreme scientific versatility" could attempt to write it (Anon 1935; Dingle 1935).

Internal inspection shows that Westaway's sources included the British Library and books borrowed from H. K. Lewis, the scientific and medical library

---

[34] One teacher thought he had "done his work well". See Anon (1927).

[35] For context, see Hudson and Walmsley (2005).

[36] Unfortunately, because in most scholarly libraries books are catalogued by authorship, it is not possible to identify all the books in the series except serendipitously.

[37] 2nd ed. 1935 with minor corrections only; reprint 1936. Chinese translations 1937 and 1966, Czech in 1937. The book of 1,080 pp was dedicated to his daughter.

in Gower Street, the *Encyclopaedia Britannica* and *Nature* as well as his own well-stocked library. The ready availability of Boyle's *Sceptical Chymist* and Harvey's *On the Motion of the Heart* in the Everyman Library enabled him to give detailed accounts of their experiments and reasoning. Westaway's historiography was surprisingly sophisticated for a period when accounts of science were usually triumphalist and Whiggish. When discussing Babylonian mathematics and astronomy, for example, he scorns any reader who condemns the Babylonians for not formulating hypotheses to explain their observations of heavenly events. How would the reader determine the length of a solar year? No reference books allowed, the problem had to be solved by thought alone. By setting the reader such rhetorical questions, the Babylonians' ability to determine that the solar year was $365^1/_4$ days long without using instruments became all that more impressive. The same device is used at the end of the book when Westaway sets the reader 20 thoughtful and probing questions. Two contrasting questions, one based on bookwork and the other more diffuse and philosophical, will suffice to illustrate his purpose:

> What is an explosion? How long does it take a high explosive like T.N.T. to be converted into a gas? Explain why such a gas is so remarkably destructive, why its downward action is so violent, and why it does not expend its force upwards into the atmosphere.
>
> On being established in 1899, the Board of Education adopted the traditional views of the Science and Art Department of the Privy Council, which the Board succeeded, that physics and chemistry were the most suitable subjects of science for teaching in schools, views which still generally survive. To what extent do you consider this to be the cause of (1) the ignorance of, and (2) the lack of interest in, science by the average educated Englishman? If it is the cause, what is the remedy? If not the cause, what *is* the cause? (Westaway 1936, pp. 1037–1040)

73.7 Broadening Science Education

When looking back on his long career as an educator, Westaway was pleased by the way changes in teaching and educational practice had remoulded the minds of the younger generation. He was particularly struck by the way that the creation of sixth forms in secondary schools had led young people to become critical, well informed and opinionated. In one of his last, and perhaps oddest, books, Westaway encouraged intellectual debate among young people by providing raw materials for philosophical discussion and debate. He agreed completely with the views of the political historian Sir Ernest Barker who had written in *The Times*:

> At the end of a life spent in teaching, I am an educational anarchist so far as concerns the growth of true minds. When I find a true mind, I want to let it grow. Conscience used to make a coward of me, and I was once resolved to be a good tutor. Either I have lost my conscience, or it has acquired a finer edge. At any rate, I am now disposed to be very tender to the liberty of young minds. Their liberty includes their freedom from me. I insult them if I tell them first what to read – still more if I tell them what is 'the right view'. They need their own intellectual adventures. If they ask me to go with them, I am proud to be asked: if

> they ask me questions, I will tell them what I think – and I will add that I am far from being sure about it. (Barker 11 August 1937)[38]

Westaway's curiously titled *Obsessions and Convictions of the Human Intellect* (Westaway 1938a) from which this quotation comes contained a variety of informative and unbiased essays on subjects that were likely to interest young people between the ages of 16 and 25. Carefully excluding politics, the subjects ranged from astrology and alchemy, perpetual motion and the fourth dimension to questions about the nature of space and time, miracles, religious persecution down the ages and the concept of Hell ("atrocious" and "immoral"). Much of this curious work, which was aimed at providing a critical synoptic view of modern knowledge for pupils exposed to overspecialisation, was cannibalised (albeit reworked) from his other books. The first impression sold out immediately and was reprinted with a different, and probably more appropriate, title *Man's Search after Truth* (Westaway 1938b).[39] The book, which must have been an essential volume for school libraries, ends typically with a series of questions for the reader, but in this case they were questions that had all been suggested by young people when talking to Westaway.

The idea for *Appreciation of Beauty*, which Westaway published in 1939 soon after Chamberlain had negotiated "peace in our time" with Germany, came from the chapter on aesthetics that he had added to the third edition of *Scientific Method* in 1924. Echoing Robert Bridges' famous poem, dedicated to his wife Mary, on first reading it appears to address science students and scientists who may lack an appreciation of the arts, but a closer reading suggests that he had in mind a more general readership that felt it lacked an appreciation of "high culture" (Westaway 1939).[40] The book is, in fact, a vade mecum of culture offering guidance on how to understand and appreciate painting, sculpture, the history of art, architecture, ornament, arts and crafts, landscape and garden design, literature and music all underpinned by a philosophical discourse on aesthetics. In the final chapter, "What is meant by the beautiful", partly reworked from the third edition of his *Scientific Method* (1924), he concluded that Art "in the highest sense" involved "the reproduction of the phenomenon of nature" (e.g. sights and sounds), an "expression of the thoughts and emotions of the artist" and the embodiment of both these factors in "an external product like a painting, a statue, a cathedral, a piece of ornament, a garden, a poem, or a symphony" (Westaway 1939, p. 195). At the end of the day, beauty, he decided, had nothing to do with accepted canons of beauty or the consensus of experts. Nor could it be a Darwinian evolved sense that provided some kind of survival value. The appreciation of beauty was a form of communication from one human spirit to another, and because this communication was individual and personal, it was incapable of objective examination. Although the appreciation of beauty was undoubtedly a variable function of a person's education, experience, beliefs, traditions and

---

[38] Sir Ernest Barker (1874–1960), as quoted in Westaway (1938a, p. xi)

[39] Pagination and content were identical to *Obsessions and Convictions* (Westaway 1938a). See the enthusiastic review in *Nature* (Anon 1938).

[40] Robert Bridges' final poem, *the Testament of Beauty*, had appeared in 1929.

customs, ultimately Westaway agreed with Robert Bridges that man's appreciation of nature and man-made art was God given – a conclusion he instantly qualified as an unverifiable hypothesis but one that gave him the greatest degree of personal satisfaction.[41]

The Appreciation of Beauty is fascinating in respect to what it reveals about Westaway's own tastes, as well as implying that he had studied art at the Royal College of Art in the 1880s where he had learned to draw accurately. In contrast to his progressive appreciation of modern science, he stands revealed as a very conservative connoisseur of painting. Good art had to be representational and to tell a story. Although well read on Victorian and Edwardian art criticism, Westaway completely ignored artistic developments since the pre-Raphaelites. Indeed, art since the Impressionists deserved to sink without trace. Not for him Kandinsky's appreciation of the spiritual nature of abstraction. The literary canon ended with Arnold Bennett. He detested jazz bands: "what front-rank musician has any real respect for a Jazz Band?" Live music was better than recorded music or music transmitted by wireless. Such opinions make him sound like an elderly schoolteacher whose fixed opinions had never altered. Despite this conservatism, Westaway's guide would have undoubtedly benefited a reader who wanted to improve their appreciation of high culture. Despite some "old-fogey" opinions and a decidedly deficient coverage of culture after about 1890, any reader would have received a lot of sensible advice of how to view pictures (e.g. where best to stand), how painters and sculptors achieved their optical effects, the need to know the Bible, classical myths and saint's lives to fully appreciate an artists' intentions and a contemporary guide to Britain's best museums and art galleries.

73.8 Westaway's Religious Views

Anyone reading Westaway's *Appreciation of Beauty* in isolation from his other writings might well assume that he held extremely orthodox religious views. They would be mistaken. There was a general tendency among thinkers to take stock of the human race after the cataclysmic First World War. Westaway was but one of many philosophers, theologians and scientists who, in the light of evolution and the emergence of modern physics and cosmology, published their views on the relationship between science and theology (Bowler 2001).[42] Like many other early twentieth-century scientists, theologians and philosophers, he was concerned to reintegrate science and religion by demonstrating that the Victorian forms of materialism no longer appealed to scientists. That being the case, the churches had to modernise and bring their teachings into line with contemporary science. *Science and Theology: Their Common Aims and Methods* appeared in 1920 and was

---

[41] Westaway acknowledged that in writing the final chapter, he had received "great help and friendly criticism" from the philosopher and statesman, Arthur Balfour (1848–1930).

[42] Bowler did not notice Westaway's contribution to the debate.

reissued in an enlarged edition in 1934. It can be considered as an appendix to his *Scientific Method*.[43] His aim was to present the scientific developments of the past 50 years in layman's language and show their provisional nature. Because science was now a fundamental factor in human life and progress, he argued, any religious system had to find ways to accommodate it. Religious divisions were largely caused by a failure to accommodate new knowledge, and he appealed to Christians especially not to consider only their own doctrines as true and valid.

Reviewers were delighted by the book's directness and lucidity of style in dealing with matter, space and time, the genesis of the earth, the evolution of animal species, the antiquity of man and the emergence of life and consciousness (Sarton 1921; Anon 1920).[44] Westaway's conclusions were blunt: the belief that the same atoms of our bodies would reassemble on the day of judgement to form a human being was a pagan superstition; to express a belief in the resurrection of the body merely emphasised the material aspect of religion and was unnecessary; what really counted was a belief in the survival of personality. It followed that a belief in Christ's literal resurrection was unnecessary since what counted was the survival of Jesus' personality. Westaway accepted that the Bible had not been divinely inspired, but in accepting evolution he made it clear that it was meaningless if not teleological. A long, and erudite, section on controversies and heresies within the early church demonstrated how much theological clutter and primitivism needed to be eradicated from Christian doctrines. The "unbending institutionalism" of the church had to be eradicated. Westaway's convictions were clearly those of the Broad Church, an idealist philosophy and theistic belief:

> Theism has been aptly described as a systematized body of doctrine in which it is shown that an intelligent First Cause is the necessary and inevitable presupposition of experimental science, of reasoned knowledge, of aesthetics, of ethics, as well, of course, as of religion. If we want to explain our conceptions of the Real, the True, the Beautiful, or the Good, in each case alike we are inevitably driven to the conclusion that without an intelligent First Cause as a Beginning or Foundation, the whole of our scheme must dissolve and leave not a rack behind. (Westaway 1932, p. vii)

Once again he thanked Lord Rayleigh, who had died in June 1919, for his help with the manuscript, which was completed 2 months later. In a note added in proof, he observed that Einstein's "hypothesis" of relativity had been apparently verified – or, rather, just one of its consequences had. He remained doubtful, however, because he could not see how gravity acted in a void and he found the theory contradictory regarding the variability of time. However, by the time of the second, enlarged edition in 1932, Westaway had come to terms with relativity, stressing that we must carefully distinguish between *abstraction* which subtracts from observations and *hypotheses* (like relativity) that added to observations. The whole tendency of modern science, he noted in the light of quantum mechanics, was away from dogmatism and towards less certainty.

---

[43] Indeed, chapter 1, "problems of philosophy", is largely a reprint of the final chapter of *Scientific Method* (Westaway 1912).

[44] Sarton (1921, p. 120) thought the book "very good indeed". The *Nature* reviewer (Anon 1920, p. 608) thought "the theology student is left without excuse".

73.9 Westaway's Personal Beliefs

What of the man himself? As a teacher, he was evidently both successful and something of a pioneer, using, for example, three-dimensional molecular models in the earliest days of his classroom career – namely, the 1880s:

> When I first taught organic chemistry… I bought … a gross of small wooden balls into which I screwed midget hooks. I wanted the boys [sic] to visualise molecules as three – dimensional things. (Westaway 1937b, p. 311)[45]

Westaway was not, of course, beguiled by this use of molecular models. Noting that his pupils "loved to play about with and interchange the coloured sub-groups of atoms", he asks:

> Which was the more immoral – to let the boys think that those 'molecules' were truly representative of nature, or to waste the school time in that way?

His answer was that "scientific laws are fundamental, and scientific hypotheses are useful, but scientific shams are an abomination".

It is clear from all of Westaway's writing that he was a notable scholar, with an unusual breadth of knowledge and an abiding commitment to understanding and promoting science as an endeavour dedicated to improving the sum of human happiness and well-being. The use and meaning of words were important to him, although he was no pedant, and in several of his writings, he exposes the ways in which convictions and prejudices hold sway in matters that should be governed by reason. His commentary upon the teaching of general science being promoted by the Science Masters' Association in the late 1930s is characteristically balanced. Although he welcomes the broadening of the science curriculum that the innovation represented, he commented that while "all reformers see pretty clearly the effects of action, … they seldom look far enough ahead to see the ultimate effects of a reaction", a warning that general science should not be reduced to serving up "juicy tit-bits all the year round" (Westaway 1937b).

He was also a man of his time, writing favourably of positive eugenics and sarcastically of antivivisectionists,[46] and although careful to deny gender bias and that he consistently referred to boys (rather than pupils) for convenience, the general impression one has from reading all of his books is that he did not think girls benefited much from courses in science. His professional duties and his writing inevitably meant that he worked to a strict timetable, but it is clear that he doted upon his daughter. He found time to teach her mathematics for two hours each Saturday morning to help her prepare for her secondary school entrance examination. The evidence is that both father and daughter found these sessions stimulating and

---

[45] Such "glyptic" models had been first demonstrated by August Wilhelm Hofmann in the 1860s and could be purchased from instrument makers – to the disgust of the anti-atomist, Sir Benjamin Collins Brodie, professor of chemistry at the University of Oxford. See Brock (1967).

[46] "When the Anglo-Saxon or the Celt engages in a war of reason *v.* sentiment, sentiment almost invariably proves the winner" (Westaway 1936, p. 923).

enjoyable, Katherine describing them in later years as the highlight of her week (Kitchener 1981).[47] They were also undoubtedly successful, as Katherine found the mathematics component of the examination "too easy for words". Nevertheless, Westaway made it plain in his writings that he believed the average mathematical ability of girls was lower than that of boys and that their interest in mathematics was less. He even went so far as to suggest that the majority of girls did not need to study mathematics beyond the age of 13.

He was also a language purist, urging teachers to avoid the word "scientist" while admitting that the more correct term *sciencer* (analogous to astronomer) did not trip easily off the tongue,[48] and urged teachers to insist on the indicative mood when pupils wrote up their laboratory notes. As an inspector, he was highly regarded by his colleagues, while those he inspected found him astute in his judgement, constructive in his comments and unfailingly courteous in his dealings with people. He was unusually, perhaps, a welcome guest in many school staff rooms.

What, other than the deployment of science in war, prompted Westaway to place science "in the dock" and invite his readers to judge its guilt? Of what crime did science stand accused? Any answer to this latter question must, in part, be conjectural, but the "verdict" delivered by Westaway at the end of *Science in the Dock* and the text itself provide important clues. Reviewing, from the perspective of 1942, the position of science in relation to war, civilisation, education and religion in a rather muddled manner, Westaway ultimately leaves the verdict for the reader to decide. However, he suggests that a Scottish jury would bring in a verdict of "not proven" and that almost any jury would append to its verdict "the rider that science seems to be rather indifferent to the results of its work on the happiness of humanity". In addition, the jury would not improbably express the opinion that "not a few of the men who devote their lives to unearthing the secrets of nature really think less of the welfare of mankind than of their own enregistration on the roll of personal fame" (Westaway 1942a, p. 128).

Throughout his life, Westaway had tried to bridge the gap between science and the humanities, and, as noted above, he held firmly to the view that scientific knowledge should be directed towards the greater good of the human race. The collapse of humane values represented by the Second World War and its associated technology of destruction were thus a challenge to the ideas which Westaway had espoused and promised for many years. The publication of *Science in the Dock* in 1942 can be seen both as a personal exploration of the issues surrounding the social relations of science in the strained circumstances of a nation at war and as an attempt to reassert the importance of science as a humane endeavour. It can also be seen as an attempt by Westaway to expose the consequences of the early specialisation that marked English secondary education and to emphasise the need for breadth and balance. From the perspective of the early twenty-first century, however, one is also left to wonder about Westaway's attempt to reconcile his personal beliefs about science

---

[47] For further information on Katherine Westaway, see Hunt (2004) and Godber and Hutchins (1982).

[48] Here he followed Gregory, *Nature's* editor. *Nature* did not use the word scientist until the 1940s.

and the Christian faith. Again, conjecture is inevitable, but his books on the aims and methods of science and theology suggest strongly that he accepted the notions of a first cause and a directing agency behind the natural phenomena that scientists made it their business to explore (Westaway 1920, Chap. 12).

Frederick William Westaway died from bladder cancer on 25 February 1946 at the age of 81. His personal papers have not survived. Unlike many of his colleagues in the inspectorate, he was never accorded an honour, nor did he have an entry in *Who's Who*, and the teaching press ignored his passing. His one and only obituary notice in the *Bedfordshire Times* simply recorded that his "kind and scholarly face will be missed".[49]

73.10 Conclusion: Westaway's Legacy

Westaway was but one of an army of HMIs whose support, criticisms and writings have contributed to science teaching over the past 150 years in ways that deserve fuller investigation by historians of education. We hope that this essay will encourage others to investigate the role of inspectors in encouraging and promoting science education.[50] In this essay we have highlighted the career of just one HMI whose contribution seems to have been of exceptional importance. Westaway was a somewhat unusual recruit to the inspectorate for most were Oxbridge graduates.[51] However, the range of his reading and expertise put him among the best graduates from Cambridge's mathematical and natural science tripos – the graduates he himself believed were the very best qualified to be excellent science and mathematics teachers. As Eric Holmyard commented, after reading Westaway's writings, a harassed schoolmaster will, after all, appreciate the usually dreaded attentions of an HMI (Holmyard 1929).

---

[49] At the time of his death, the Westaways and their daughter were living in de Parys Road, Bedford, adjacent to Bedford School. At Probate in Oxford, 26 April 1946, his estate was valued at £4,604 (about £138,000 in today's buying power) and willed solely to his daughter, presumably because of his wife's incapacity. Mary Westaway died on 9 March 1947. All three Westaways are buried in the churchyard of All Saints, Renhold, where the family evidently worshipped.

[50] However, HMI reports of science lessons can be disappointing as source material. HMI visits were infrequent and often focused on different aspects of a school's work, making comparisons difficult. For a guide, see Morton (1997).

[51] For example, Charles Thomas Whitmell (1849–1920), BSc (London), NST (Cambridge), taught chemistry and physics at Tonbridge School before joining the inspectorate in 1879 serving in Cardiff (1879–1887) and at Leeds until retirement in 1910; Frederic W. H. Myers (1843–1901) became an HMI in 1872 after teaching classics at Cambridge; Francis Bernard Stead (1873–1954), a close friend of the Westaways, had worked at Plymouth's Marine Biology Association before joining the inspectorate; and Thomas W. Danby (1840–1924), NST (Cambridge), assisted the chemist George Liveing before becoming chief inspector of schools for south-east England. For some amusing reminiscences of inspection in the second half of the nineteenth century, see Sneyd-Kinnersley, E. M. (1908).

But what, it might be asked, is the relevance of Westaway's writing to school science teaching today, given the profound changes in the social context of both science and religion?[52] Part of the answer lies in the fact that many of the issues that Westaway addressed have arguably become more, rather than less, important and that some of his arguments, lucidly and eloquently developed and expressed, continue to offer a challenge to the contemporary mind. Beyond this, some of Westaway's writing about science and education sets a standard that others might seek to follow, notwithstanding the changes that have taken place in the last half century in our understanding of the history and philosophy of science. Ultimately, however, reading Westaway forces the reader to ask questions about the educational function of science, questions that seem to be urgently in need of answers as school science education is increasingly cast in an instrumental mode, serving economic rather than humane ends.

At a time when serious doubts are again being expressed about whether practical work and experimentation should play an essential (but expensive) role in schools, Westaway's arguments are well worth reading again.[53] We can also take to heart Westaway's expectation (and challenge) that

> When a boy leaves school, he should have been so taught and be so informed that he is able to take an intelligent interest in all scientific, technical, and industrial developments. He should be able to turn up technical reports, and obtain at least an intelligent general grasp of their contents. He should be able to discuss in a council chamber the pros and cons of proposed new applications to industrial processes. In short, the former secondary school boy should be the disseminator of new knowledge and the intelligent adviser of the community. (Westaway 1929, pp. 385–386)

Because of the way that the sociology of science has transformed approaches to the history and philosophy of science since the 1960s, Westaway's *Scientific Method* is now only of historical interest. Similarly, his pioneering *Endless Quest* has been superseded by a more nuanced and critical approach to the history of science – though it has to be said that no historian has been able to provide a better encyclopaedic and illustrated guide for teachers on how scientific achievements were brought about. Its message, taken from Westaway's grasp of philosophy, that despite the "passing of dogmatism" there is no reason to suppose "that what is mathematically describable is ultimately real, and the only reality", is one that all teachers should reflect upon. Finally, despite worldwide cultural differences and national varieties of syllabuses and curricula, his *Science Teaching* and *Craftsmanship in the Teaching of Mathematics* remain inspirational and illuminating reading for both novices and experienced teachers.

---

[52] For Westaway's continuing relevance in an American context, see Keller and Keller (2005) and the electronic blog at http://www.smartscience.net. See also Matthews (1998).

[53] See, for example, Taber (2011). The issue is also highlighted by the REACH legislation on the safety of chemicals.

Acknowledgements We are grateful to Nicola Aldridge for information about the Westaway family and to Dr M. P. Price, librarian of the Mathematical Association Library at the University of Leicester, for comment on Westaway's mathematics.

William H. Brock is emeritus professor of history of science at the University of Leicester. He read chemistry at University College London before turning to the history of science which he taught at Leicester between 1960 and his retirement in 1998. His publications include *The Atomic Debates* (1967); *H. E. Armstrong and the Teaching of Science* (1973; paperback 2012); *Justus von Liebig und August Wilhelm Hofmann in ihren Briefen 1841–1973* (1984); *From Protyle to Proton. William Prout and the Nature of Matter 1785–1985* (1985); *The Fontana History of Chemistry* (1992); *Science for All. Studies in the History of Victorian Science and Education* (1996); *Justus von Liebig. Gatekeeper of Science* (1997); *William Crookes and the Commercialization of Science* (2008); and *The Case of the Poisonous Socks. Tales from Chemistry* (2011).

Edgar W. Jenkins is emeritus professor of science education policy at the University of Leeds where he was head of the School of Education (1980–1984 and 1991–1995) and director of the Centre for Studies in Science and Mathematics Education (1997–2000). From 1984 to 1997, he edited the journal *Studies in Science Education.* His principal books include *From Armstrong to Nuffield* (1979); *Technological Revolution?* (1986); *Inarticulate Science?* (1993); *Investigations by Order* (1996); *From Steps to Stages* (1998); *Learning from Others* (2000); and *Science Education, Policy, Professionalism and Change* (2001). He is currently co-editing a volume to mark the fiftieth anniversary of the founding of the Association for Science Education.

Chapter 74
E. J. Holmyard and the Historical Approach to Science Teaching

Edgar W. Jenkins

74.1 Introduction

Eric John Holmyard (1891–1959)[1] was a scholar and schoolmaster and a significant figure in the history of science and in science education during the first half of the twentieth century. Although his research into alchemy is well known to historians of science interested in early chemistry, his historical approach to science teaching has received much less attention from the science education community, the study by Kinsman (1985) being a conspicuous but unpublished exception.

Born in 1891 in Midsomer Norton, Somerset, in the West of England, his father, Isaac Berrow Holmyard, was a schoolteacher in a national school, i.e. an elementary school set up by the National Society for Promoting the Education of the Poor in the Principles of the Established Church. After attending Sexey's School in Bruton, Holmyard went up to Sidney Sussex College, Cambridge, to read history and science. He graduated in both these disciplines with a first in natural science and a second in part two of the history Tripos. After working as a Board of Agriculture Research Fellow at Rothamsted Experimental Station, he taught briefly at Bristol Grammar School and Marlborough College before becoming head of science[2] at Clifton College in Bristol in 1919.

Holmyard entered the teaching profession at a time when schooling in England was undergoing a period of significant change. The Education Act of 1902 had created Local Education Authorities (LEAs) with responsibility for publicly funded

---

[1] Although Holmyard used both his initials in all his publications, he preferred the name John to Eric (McKie 1960).

[2] The terms of Holmyard's appointment were unusual in that he was relieved of all out-of-school duties and, until 1936, lived in Clevedon and travelled daily to Clifton (Kinsman 1985; Williams 2002). His appointment at Rothamsted reflected his study of biology in Part 1 of the Tripos examination.

elementary and secondary schools, with a small proportion of pupils from the former selected to enter the latter on the basis of an examination at the age of 11. Secondary, i.e. grammar, schools under the control of the LEAs were quickly established across the country, and many chose to organise themselves on the basis commonly associated with the public (i.e. private) schools, creating houses, appointing prefects and promoting competitive sporting activities. However, unlike the public schools, the curriculum of the LEA grammar schools was governed by Regulations issued annually by the Board of Education which required the teaching of both practical and theoretical science. Despite the experience of pioneering schools like Clifton College, much remained to be learnt about best to organise and teach science in the grant-aided secondary schools, 1,027 of which were established by 1914 (Simon 1974, p. 363). There was therefore much debate about the order and manner in which topics should be presented and taught and about the roles to be accorded to expository teaching, teacher demonstration and laboratory work conducted by pupils (Fowles 1937; Jenkins 1979). For reasons that are discussed below, that debate became particularly significant in the years following the end of the First World War.

This essay reviews Holmyard's contribution to the historical method of science teaching and comments upon why the history of science has featured so prominently in the history of school science education.

74.2 The Historical Method of Teaching

Founded in 1862 under the headmastership of John Percival, Bishop of Hereford, Clifton College was somewhat unusual among the 'public' schools in England in the mid-nineteenth century in that it 'took science seriously' (Brock 1996, p. 373). It was a legacy upon which Holmyard was able to build. Under his leadership, the College acquired an astonishing collection of manuscripts and first editions of scientific works for its new library[3] and established an outstanding reputation for its science teaching. According to the author of the relevant entry in the *Dictionary of National Biography*, 'Under his guidance, Clifton established a reputation for science probably unequalled, and certainly not surpassed, by any other British school' (Williams 2002; see also Williams 2004).

Holmyard was an enthusiastic advocate of a historical approach to the teaching of chemistry which helped pupils to learn how discoveries were made and, more particularly, to familiarise themselves with the ideas in the minds of the researchers

---

[3] The Library, known as the Stone Library, was built with funds from Old Cliftonians. The first editions purchased for the library included Newton's *Opticks* and Darwin's *On the Origin of Species*. Clifton College also purchased material at Sotheby's 1936 sale of Newtoniana. Opened in 1927, Holmyard was justifiably proud of the new Science Library which he believed had 'no rival in any school in the world' (Holmyard, writing in the *Cliftonian* of June 1927 and quoted in Williams 2002, p. 204).

and to understand the methods by which they had overcome difficulties. His advocacy reflected a deep scholarly interest in the early history of chemistry, notably in alchemy, at a time when the history of science was becoming established as a distinct academic discipline: the journal *ISIS*, for example, was founded by George Sarton in 1912 and Department for the History and Methods of Science Department at University College London in 1921. Holmyard taught himself Arabic and acquired a good working knowledge of Hebrew, skills which enabled him to edit several important Islamic alchemical texts and to shed light on the work of early alchemists, research for which the University of Bristol awarded him a D. Litt. in 1928. He was in demand as a reviewer for several journals, including *The Journal of the Royal Asiatic Society*, reviewing publications in French and German as well as English. He served (1947–1950) as a vice-president of the newly formed British Society for the History of Science and later as an ordinary member of its council (1953–1954) and as chairman of the Society for the Study of Alchemy and Early Chemistry. He was also a corresponding member of L'Académie Internationale de l'Histoire des Sciences.

In a detailed review of approaches that had been recommended or used to teach chemistry, the schoolmaster George Fowles[4] suggested that a historical approach could be biographical, recapitulatory or be based upon the evolution of scientific ideas (Fowles 1937, pp. 511–18). The first of these relied on the biographies or published diaries of famous scientists and was sometimes coupled with the anecdotal in an attempt to relate the research of individual scientists to wider social, economic or political concerns. The work of Haber on nitrogen fixation is an obvious example. The recapitulatory approach was adopted by Perkin and Lean in their *Introduction to the Study of Chemistry*, first published in 1896 (Perkin and Lean 1896).[5] Convinced that 'the order in which problems have presented themselves to successive generations is the order in which they may be most naturally presented to the individual', they claimed that many of the chapters had been worked through by elementary students in the laboratories of Owens College, later the University of Manchester (Perkin and Lean*op.cit.*, pp. vii-viii and xi). However, the recapitulatory approach does not seem to have been widely used, partly because it involved devoting time to teaching ideas and processes that had long been superseded or could be taught much more effectively and economically in other ways. Fowles, writing a generation later, suggested (*op.cit.,* p. 515) that the approach could work well only when controversy and blind alleys did not significantly interrupt the presentation of the historical narrative. His overall judgement (*op.cit.*, p. 514) was that the 'much vaunted' recapitulatory method had 'never been faithfully carried out in practice'.

---

[4] For Fowles, see Jenkins (2000). Fowles was a close friend for over thirty years of John Bradley who regarded him as his 'friend and mentor' and his book as 'indispensable to the teacher of chemistry' (Bradley 1988, p. 2).

[5] Perkin and Lean's book held 'a position of honour' on the bookshelves of John Bradley who was introduced to it by his teacher at Archbishop Holgate's Grammar School in York, Henry Worth (1870–1949). Bradley was a distinguished teacher and teacher educator who was much influenced by the writings of Mach and who taught at Christ's Hospital where he met H. E. Armstrong (Bradley *op.cit.*).

The evolutionary approach was intended to help students understand the personal, intellectual, professional, economic and social factors that characterised the historical path towards the current understanding of natural phenomena. The value of this approach lay in countering the view that former ideas were simply the absurd outcomes of prejudice or mistaken judgement and in understanding the qualified degree of confidence that should be placed in more contemporary explanations of natural phenomena.

> We like to be thought devotees of truth uninfluenced by prejudice, as open-minded and serene students of nature, free from suppositions and welcoming every fact that comes within our ken… When the errors of our predecessors are forced upon our notice we may lament them or be amused or may seek to excuse them, but that the same lamentations and excuses may some day have to be made for us we can hardly think possible. (Lodge 1925, p. i)

Although he never referred to it as such, it is this evolutionary approach that most aptly describes Holmyard's historical method of teaching chemistry. He argued his case at a vacation course for science teachers held in Oxford in the summer of 1924[6] and in an article published in the same year in *The School Science Review*, the journal of the Science Masters' Association, an organisation of which he was a committee member and, a year later, president (Holmyard 1924a, pp. 227–33).

He began by addressing the widely held belief that school chemistry could be taught in two ways, depending upon whether the students would eventually become chemists or not. For the former group, the emphasis was placed on the grammar and syntax of the discipline, on learning the rudiments of canonical chemistry. For the latter, the 'chemistry of everyday life' was usually accorded priority. For Holmyard, this distinction was 'a grave fallacy' that rested upon 'the fundamental misconception that chemistry is a craft, when essentially it is a philosophy' (*ibid.,* p. 227). He was thus scornful of the enduring educational merits of snippets of chemical knowledge that enabled someone later in life to solve an acrostic in a daily newspaper or to understand that 'the 'will o'-the-wisp' is caused by the combustion of marsh gas…produced by the action of little insects, called germs (*sic*), upon dead plants' (p. 228). He does not, however, suggest that knowledge of this kind is to be regarded as having no value. On the contrary,

> …how often, after having cut myself while shaving, have I thanked Heaven that my chemical education had been carried to such a degree of perfection that I knew a trivalent cation was especially effective in the coagulation of colloids!

He then adds, in a remarkable sentence, that

> Merely to have rubbed on alum in an unintelligent way would have robbed the operation of all its ecstasy, and I should not have felt that piquant sense of superiority over my daily companion in the train, Lucas, the stock-broker, who is so ignorant that he doesn't even know the empirical formula for the starch in his own collars! (p. 229)

This is one of several examples in Holmyard's article of what he called 'levity', the intended irony of which could all too easily be misunderstood. However, all the

---

[6] Holmyard's contribution to the course was subsequently published as a pamphlet entitled *The Teaching of Science* (Holmyard 1924b).

examples served to introduce his main argument, namely, that the chief value of chemical education stemmed from the precise, logical and formal character of the discipline, not from its personal or economic utility. He then went on to address the question why chemistry has an educational advantage over other disciplines, such as mathematics, which can be characterised in similar terms. His answer was that chemistry appeals both to intellect and to emotion and is not a 'cold, discarnate scheme of mental gymnastics' (p. 231).

Claiming that 'the immediate [favourable] reaction to biographical details is a universally recognized trait of youthful psychology', Holmyard asked who 'could fail to be stirred by accounts of Pasteur's romantic search for *l*-tartaric acid, of Priestley's discovery of oxygen, of Moissan's isolation of fluorine?' He claimed that he had successfully used his historical approach with his own students at Clifton.

> Personally, I have never found any difficulty in getting a boy to 'believe' in the 'truth' of the sulphur-mercury theory of metals, to get him to abandon it for phlogiston theory, or to abandon this in turn for the oxygen theory, with the result that the last theory is regarded by him in a very different way from that in which a boy looks at it who has had it taught to him dogmatically (Holmyard 1924a, p. 232).

In addition to arguing for, and illustrating, Holmyard's historical approach to teaching chemistry, his article in *The School Science Review* also provides some insight into his understanding of the philosophy of chemistry. It is clear that, for Holmyard, this understanding did more than support his historical approach to chemical education: it provided its underpinning rationale. Only by adopting such an approach could students be led to understand that 'Science in general and chemistry in particular are but conceptual schemes which must always bear an unknown relation to the precepts they correlate' (p. 231). Elsewhere, he invokes a biological analogy to express his view of the history of science.

> '…the theory of evolution is applicable to the development of science no less than to the world of birds, beasts and flowers. (Holmyard 1925c, preface)

For Holmyard, scientific knowledge is to be regarded as essentially pragmatic, not connected with questions about the nature of reality, and as free of any special ontological assumptions and untainted by narrow questions of economic benefit. For the anonymous reviewer of his pamphlet, *The Teaching of Science*,

> Mr Holmyard is not concerned with a universe of absolute truth and rigid law, but with a humble and tentative hold on the precarious hypothesis of an external world. (SSR 1925a, p. 266)[7]

Almost twenty years later, Holmyard wrote that

> Reality, if it is to be discussed at all, must for the present be discussed as a philosophical problem, and the scientist as a scientist need not adventure into such regions…a theory is merely a conceptual model of perceptual facts…a tool rather than a creed. (Holmyard 1944, p. 126)

Holmyard's concern to put some distance between the discipline of chemistry and its uses brought him into conflict with his fellow members of the Science Masters' Association (Layton 1984, p. 203).

---

[7] Unless otherwise indicated, all reviewers were anonymous.

> …any scheme that sets out to be utilitarian, in the narrow sense of the word, or merely ‘interesting’ is blatantly immoral, and rightly deserves the censure it invites. (Holmyard 1924a, p. 230)

He therefore had no time for the courses of ‘General Science’ which the Association was strongly promoting in the interests of ‘science for all’.

> I am…with those who cry ‘Science for All’ but I would add ‘and Dabbling Science for Nobody’. I have no sympathy with kindergarten schemes of ‘general science’. [They are] fallacious and shallow…. (Holmyard 1924a, p. 229)

If students of science are to be helped towards what Holmyard described as the ‘truth’, only the historical method of teaching could bring this about.

> The historical method is not, I believe, one of several equally good alternative schemes of teaching chemistry in schools: it is the only method which will effectively produce all the results at which it is at once our privilege and duty to aim (*ibid.*).

In addition, it was only the historical method that could enable students to appreciate to the full ‘the serene joys of the intellectual life’ and steer school science education in a much needed new direction.

> …the main result of the teaching of science in our schools has been to accelerate the spread of that contempt for and indifference to ethical, moral and aesthetic values, and to spiritual and religious truth…perhaps the chief characteristic of our civilisation. (Holmyard 1925b, p. 490)

Nothing less than a fully worked out historical approach could bring this about and he cautioned that

> Many teachers, in all good faith, imagine that they are adopting this method [of teaching] if they drag in a few biographical details…fascinating as it may be, and valuable as it certainly is, in stimulating the child’s interest and attention, it does not by itself constitute the historical method. (*ibid.,* p. 492)

Holmyard’s views were supported by J. W. Mellor, FRS, author of several textbooks and of a landmark multivolume *Comprehensive Treatise on Inorganic and Theoretical Chemistry.* Asserting that ‘every teacher now recognises that it is a sheer waste of time to introduce many abstract ideas into an elementary science course without a previous survey of the facts from which the generalizations can be derived’, Mellor[8] argued that ‘in most cases the historical mode of treatment is correct, because the generalizations have usually developed from contemplation of the facts’ (Mellor 1932, preface).

---

[8] Joseph William Mellor CBE, FRS (1869–1938) was born in Lindley, a suburb of Huddersfield in the West Riding of Yorkshire, but left for New Zealand at the age of 10. He returned to England in 1899 to take up an appointment as chemist to the Pottery Manufacturers Federation in Newcastle – under Lyme. Mellor soon established himself as a researcher of international standing, working on the structure and properties of ceramic materials. In 1934, he was appointed director of the new laboratories of the British Refractories Research Association, named in his honour. In addition to his monumental multivolume treatise on inorganic chemistry, he was a highly competent mathematician, and his book on mathematics for chemists and physicists became widely used (Mellor 1902).

74.3 Criticism of the Historical Approach

Holmyard will have been well aware that the historical approach to teaching science also had its critics. The pioneering Cambridge chemist, Ida Freund, author of a seminal book, *The Study of Chemical Composition* (Freund 1904), had little time for such an approach. She fully understood the importance of understanding the history of a scientific discipline and had written a prize-winning historical study of the constitution of matter, some of which almost certainly influenced the approach taken in her 1904 book. Nonetheless, to those who wanted students to retrace the paths by which scientific discoveries had been made, she replied that

> Even if such a plan could be consistently adhered to …it is better to take the shorter way to the goal, this being after all a way by which the discovery might have been made. (Freund 1904, quoted in Fowles, *op.cit.*¸ p. 513)

In 1929, in a book entitled *Science Teaching: What it was – What It Is – What it Might Be*, F. W. Westaway[9] warned that

> if the historical method is to be adopted, the general method of the history teacher must be followed…What is the point of discussing Roger Bacon and his work unless a boy first understands something of the spirit of mediaevalism – any person who attempted to unravel nature's secrets must be an emissary of Satan himself, and punished accordingly. (Westaway 1929, p. 32)

For Westaway, this condition meant that 'teaching in accordance with historical sequence' could not 'be recommended for subjects usually taught up to the fifth form [i.e. about the age of 16] –physics, chemistry and biology' (*idem.*). He was cautious of the slow progress that the historical method allowed, advising that 'it simply does not pay to spend a whole lesson over, say, the phlogiston hypothesis'. Even so, he felt that some aspects of school science, such as astronomy, were well suited to being 'developed historically and to great advantage' (*ibid.* p. 31).

In 1930, the historical method and Holmyard in particular were the subject of criticism by H. H. Cawthorne. A graduate of King's College London, Cawthorne had worked in teacher education at the University College of the South West, Exeter, before taking up a post at Firth Park secondary school in Sheffield. In his *Science in Education* (Cawthorne 1930), he devoted a whole chapter (pp. 66–75) to the historical method which he is careful to distinguish from a more narrowly biographical approach to school science teaching. While acknowledging that the historical method of teaching has merits, including preventing a 'dogmatic treatment of present-day thought', Cawthorne challenged the notion that the standpoints of the student and of the scientific discoverer are roughly the same. He concluded that it was not necessary for students to 'wade through all the mire and clay of controversy' which have, at times, been obstacles to the progress of science. His advice to teachers was that in order to prevent confusing students or using excessive time, it was necessary to 'short-circuit' some parts of the full historical argument. As a further obstacle to

---

[9] For Westaway, see Jenkins (2001) and Brock and Jenkins in this volume.

teaching in the way advocated by Holmyard, he reminded his readers that the mind of the mid-twentieth-century student was packed with ‘many odd scraps of information which the most fertile imagination of the seventeenth century philosopher could never have supplied’. He offered the example of liquid air, a concept familiar to many of his students but which would have nonplussed the early members of The Royal Society (*ibid.,* p. 75). Today, when scientific ideas and explanations are widely available in museums and the print and broadcast media, Cawthorne’s point is even more telling.

For another schoolmaster, Fowles, writing in 1937, while the historical method of teaching chemistry was ‘attractive in theory’ and ‘appealed to the philosophically minded…few had drawn up a scheme or work or attempted to put the method in practice’ (Fowles *op.cit.*, p. 513). He wondered whether students, helped by their teacher to understand that a theory was no longer tenable, might be puzzled why it was retained in the face of new experimental evidence by ‘men of the depth of intellect of Priestley and Cavendish’. He asked who, ‘Notwithstanding the simplicity of the experiments …decomposes mercuric oxide with the heat of the sun concentrated by means of a 12-inch lens…when oxygen is much more easily prepared by other means?’ (*op.cit.*, p. 514). His judgement on the historical method was that ‘one is constrained to believe that the students have done little more than accept the belief of the teacher’ (p. 517).

However, there was more to Holmyard’s advocacy of the historical approach to science education than the insights it could offer into what today is referred to as ‘the nature of science’. It also added a much-needed human dimension to the subject.

> If Science is to retain the honourable place it has won in the educational system of this country…we shall have to recognise that is the greatest of the “humanities”, and deliberately abandon the so called “utilitarian” standpoint. (Holmyard 1922, preface)

It is interesting to place Holmyard’s rejection of the ‘utilitarian standpoint’ alongside the view of Harold Hartley, FRS,[10] a distinguished physical chemist and contemporary who saw science

> …not merely as an academic subject- nor only as a basis for applied technological development but as a great cultural adventure that comprised both of these: as an historical sequence, having its nourishing roots in the past and its growing branches thrusting constantly into the future. (Ogston 1972, p. 366)

Holmyard was by no means without support in seeking to present science as a humanity. Turner, in her account of the history of science teaching in England, came to the conclusion that

---

[10] Sir Harold Brewer Hartley, C.H., FRS, was taught chemistry by H. B. Baker at Dulwich College in London who encouraged him to read and buy old chemistry books. Hartley went on to Balliol College, Oxford, to develop a lifelong interest in the history of the discipline. During his long life he held a variety of academic, business and industrial appointments. He secured the Lewis Evans collection of scientific instruments for the University of Oxford and was a frequent contributor of historical articles, especially about nineteenth-century English chemists, to the *Notes and Records of the Royal Society* of which he was the editor for eighteen years. The preface to his *Studies in the History of Chemistry* (Hartley 1971) reveals that the book was commissioned nearly 70 years earlier!

> …if science teaching is to mean anything more than the acquisition of a few tags of knowledge and a certain skill in manipulation we must accord it a place among the humanities… The human side is perhaps best introduced by a carefully selected historical treatment. (Turner 1927, p. 191)

In the aftermath of the First World War in which chemistry had played such a massive and destructive role, recasting science as a humane study was widely regarded as necessary and it helps to explain why, despite the practical difficulties of implementing Holmyard's ideas, the incorporation of at least some elements of the history of science in school curricula received a broadly sympathetic hearing.

> How necessary Science is in War…we have learnt at a great price. How it contributes to the prosperity of industries and trade, all are ready to admit. How valuable it may be in training the judgement, stirring the imagination and in cultivating a spirit of reverence, few have yet accepted in full faith. (Natural Science in Education 1918, para.4)

Reaction to the role of science in the First World War was not the only influence at work in seeking to 'humanise' school science. During the 'battle of the books' that had broken out in the middle of the First World War, supporters of a classical education had reacted vigorously to the claims of a self-styled 'Neglect of Science Committee' established to promote science education and research (Jenkins 1979). Ramsay MacDonald told the House of Commons that this committee was 'practically telling us to clear the humanities out of our schools' (Hansard 1916, col. 906), and an editorial in *Blackwood's Magazine* in 1916 described the 'ferocious attack on the humanities as evidence of the 'unbalanced men of science who wish to kill off all learning other than their own'. Those who had praised German scientific and technological achievements before the war now found their own evidence being used against them.

The clash between the scientific and classical contributions to education was not confined to the UK, and the battle was not always conducted in terms conducive to effecting a rapprochement. In the USA, for example, one commentator opined that 'Largely without the benefit of the Classics, it is not to be expected that [the ordinary scientist] should know what the Humanists are saying or realize his faults' (Glaser 1924, p. 30). In the UK, the distinguished Wykehamist classical scholar and educator, Sir Richard Livingstone, claimed in his *Defence of a Classical Education* that the fundamental weakness in science as a vehicle of a liberal education was that

> …[science] hardly tells us anything about man. The man who is our friend, enemy, kinsman, partner, colleague, with whom we live and [have our] business, who governs or is governed by us [never once] comes within our view. (Livingstone 1916, pp. 30–31)

It is clear that Holmyard, who regarded science as an integral part of culture, would have rejected Livingstone's claim that science 'hardly tells us anything about man'. It is equally clear, as noted above, that Holmyard thought science as it had been taught had accelerated a contempt for, and an indifference to, ethical, moral and aesthetic values and to spiritual and religious truth. It is noteworthy therefore that the Foreword to his *Inorganic Chemistry*, first published in 1922, was written, presumably at Holmyard's invitation, by a leading classical scholar, Cyril Norwood. Holmyard would have encountered Norwood when the latter served as headmaster at Bristol Grammar School (1906–1916) and Marlborough College (1917–1925), respectively, before moving on to the headship of Harrow (1926–1934). Norwood has been described as the 'quintessential insider of English education in the first half of the twentieth century' (McCulloch 2006, p. 55; see also McCulloch 1991). He was an influential source of government advice, eventually being knighted for his services to education. In 1929, Norwood published *The English Tradition of Education* which offered a deeply complacent and conservative view of the past, a past that was closely linked to the teaching of the classics in the English public and endowed grammar schools. In his Foreword to Holmyard's book, Norwood is deeply critical of the system of Higher Grade Schools that had developed in England during the last quarter of the nineteenth century (Vlaeminke 2000). Funded for the most part by grants from the Department of Science and Art, these locally controlled post-elementary schools attached much greater importance to science than many public and endowed grammar schools and provided an 'alternative' secondary education in all but name.[11] Norwood claimed that the teaching in these schools had been 'one sided' and excessively formal and that it had taken the Great War to forcibly remind the nation that things were not well. He saw Holmyard's *Inorganic Chemistry* as offering a way forward.

> [The author] knows how to teach with breadth and without exclusiveness. Its pages give information and provoke curiosity: at many points they suggest that there are other realms of knowledge of a quite different sort. (Norwood 1922, p. *v*)

It was an endorsement that one can safely assume met with Holmyard's approval.

When the newly formed Science Masters' Association held its annual meeting in 1920, there was widespread agreement that school science courses needed to be both broadened and 'humanised', although there was much less confidence about how this could be achieved. For some, the way forward lay with a broad course of General Science which 'furnished the mind' and 'gave some knowledge of the world in which we live' (Tilden 1919, p. 12). For others, it was essential to capture the spirit and romance of scientific endeavour by incorporating a biographical element into school science education, 'the history of men and the setting forth of noble objects of action' (Sadler 1909, p. *xi*). For yet others, it was Holmyard's evolutionary approach to the history of scientific ideas, or at least some aspects of it, that seemed to have most to commend it.

Unsurprisingly, each of these possible directions for science education reform presented difficulties. Despite the success that Holmyard claimed he had achieved with his own students, his historical method was the subject of ongoing debate and critical commentary throughout the interwar years. Interestingly, there appears to be no evidence that he sought to reply to his critics by, for example, writing for *The School Science Review* or publishing a more detailed and practical account of

---

[11] See McCulloch (1984). The Higher Grade Schools are seen by some historians as constituting an 'alternative road' to that represented by the traditional grammar school curriculum. They were swept away by a series of legislative changes between 1899 and 1902, although some re-emerged as secondary, i.e. grammar, schools under the control of newly created Local Education Authorities. See Vlaeminke (2000).

his historical method to which science teachers could refer.[12] Fowles (*op.cit.*, *p.* 517) expressed some admiration for Holmyard's success in 'getting a young class to grasp the doctrine of phlogiston' but questioned 'how little of elementary chemistry' could be taught along the lines advocated by Holmyard and how far it was expedient, and actually possible in the time usually available, to secure topical development along such lines. Although it is impossible to be sure how widely Holmyard's approach to school science was adopted, it seems clear that for most science teachers it presented formidable, even insuperable, difficulties. Few teachers could command the knowledge of the history of chemistry or physics required to take students back and immerse them in the period under consideration, and there is little evidence to suggest that the obstacles identified by Cawthorne, Fowles and others were successfully overcome. In a book written 'for teachers and training college students', John Brown, a school inspector for the London County Council, could do no more than advise that 'with older pupils, the study of a certain amount of *historical development'* of the subject will prove profitable (Brown 1925, pp. 45–6).

74.4 'Ships' Surgeons Are Always Truthful!'

While Holmyard's historical method may have failed to find widespread favour among his science teaching colleagues, his scholarly achievements in the history of science were able to find generous expression in his large number of school science textbooks. There are likely to be few, if any, chemistry teachers of an older generation familiar with the English education system who will not be able to recall his name. Some may even be familiar with the above quotation – of which more below.

Holmyard was a prolific author. Throughout the interwar years in particular, publications concerning the history of science appeared alongside a steady stream of school science textbooks. The British Library Integrated Catalogue lists over a hundred entries for Holmyard (although this number includes several different editions or reprints of the same book) and a large proportion of the entries relates to works published between 1922 and 1939. The 1920s alone produced *Chemistry to the Time of Dalton,* published in 1925, two translations of Avicenna (1925c) and

---

[12] A comparison with H. E. Armstrong is of some interest. Both men sought to give students an insight into how scientific knowledge was obtained and validated, although Armstrong's emphasis on the practical teaching of 'scientific method' could not be more different from Holmyard's more complex, nuanced historical approach. Unlike Holmyard, Armstrong was a vigorous promoter of his *virus heuristicum Armstrongii* and even compiled a book setting out his ideas (Armstrong 1903), although its lack of coherence made this a less useful advocate of his cause than it might have been. See, for example, Browne (1954/1966) and Brock (1973). For both heurism and the historical method of science teaching, science teachers were undoubtedly the weakest point. As individuals, Holmyard was described as a 'quiet' and 'tolerant' man (McKie 1960, p. 5), as having 'a modest and retiring disposition' (*The Times*, October 15, 1959) and an 'imperturbability of temper' (Singer 1959, p. 17), descriptions that could never be applied to the hot-tempered Armstrong who 'always made one think [but] was fond of saying that very few…were capable of doing so' (Hartley 1971, p. 195). For Holmyard's views on heurism, see Holmyard (1925b, p. 490).

a critical and important translation of the Arabic works of Jâbir Ibn Hayyân (1928a), a year that also saw the publication of *The Great Chemists*. The same decade also witnessed the first publication of over a dozen school science textbooks, some of which were reprinted or revised and remained in use for at least the next thirty years.

Some of Holmyard's textbooks were phenomenally successful. His *Elementary Chemistry*, first published in 1925, was reprinted eleven times by 1933, eventually selling over half a million copies worldwide (Holmyard 1925a). Even today, when chemistry has undergone so many profound changes, it remains a remarkably interesting book. The frontispiece is an extract of a dialogue between master and pupil from *Ye Booke of Allchimye* written in the twelfth century, its first two chapters address the questions of what chemistry is and how it arose and the book ends with biographical notes on some famous chemists. Few, if any, modern elementary school chemistry texts begin by introducing pupils to the complex, multicultural origins of the discipline, provide illustrations of Arabic chemical operations, review the multiple uses and benefits of chemistry and explain how chemistry itself came to be so called. While what follows these opening chapters is a well-ordered presentation of familiar information about the occurrence, preparation, properties and uses of the chemical elements and their compounds, few readers would have failed to find something of interest even when this was incidental to the main text. For one reviewer, the book revealed Holmyard's 'adventurous and at once recognizable style' along with his 'store of humorous delights on chemistry' (*J. Chem. Ind.* 1934, p. 882). His *Chemistry for Beginners* prompted another reviewer to comment that 'Mr Holmyard's books always please us', adding that 'he had the rare gift of writing so as to interest the young' (*J. Chem. Ind.* 1931, p. 146).

No less successful as a publication and equally well received by the book's reviewers was his *A Higher School Certificate Inorganic Chemistry* which appeared in 1939. For one reviewer, the reading and rereading of this book had been 'sheer delight', adding that it was 'not possible to write of it save in terms which appear exaggerated'. For the journal *Nature*, it was simply 'excellent'. Following the replacement in 1951 of the system of School Certificate Examinations by the O- and A-level examinations of the GCE, Holmyard collaborated with W. G. Palmer[13] to produce in 1952 a revised edition, entitled *A Higher School Inorganic Chemistry.* The above reference to the truthfulness of ships' surgeons will be found on page 272 of the first edition and

---

[13] Palmer was a Fellow of St. John's College, Cambridge, when Bradley (see note 5) was an undergraduate and gave him 'a taste for the history of chemistry' (Bradley *op.cit.*, p. 1). Holmyard also collaborated with Frederick Arthur Philbrick to produce *A Textbook of Theoretical and Inorganic Chemistry* (Philbrick and Holmyard 1956). Philbrick died at a comparatively early age. Holmyard may have felt the need for collaboration since he had given up his post at Clifton College in 1940 when the school was evacuated to the relative safety of Bude in Cornwall. Although Philbrick is identified as the lead author, the book 'was mostly Holmyard, Philbrick having been responsible for bringing later editions up to date' (Francis 2004, p. 15).

Holmyard subsequently took up the editorship of the magazine *Endeavour*. Published by ICI, the magazine sought to publicise British scientific and technological achievements. Intended as a war time publication, it proved so successful under his editorship that it continued after the war ended when it was produced in five languages (English, French, German, Italian and Spanish). Holmyard remained its editor until 1954. His obituary was published in *Endeavour*, 73, January 1960.

page 275 of the revised volume. Referring to the salvaging of 30 tons of mercury from a Spanish wreck off Cadiz by HMS Triumph in 1810, the reader is told that the symptoms of mercury poisoning quickly became evident among the crew and livestock of the salvage vessel. Lest any should doubt the word of the ship's surgeon, quoted in the text, that he 'had seen mice come into the ward-room, leap up to some height, and fall dead on the deck', the reader is referred in a footnote to the quotation cited above. In a discussion of the colloidal state on page 147 of the earlier volume, the poet Keats is invoked to describe a gel as 'soother than the creamy curd', a description challenged by the footnoted observation that Shakespeare says 'Out vile jelly!' The likening of the smell of phosphine to that of garlic prompts the comment (p. 373) that this is 'A base libel on a plant recommended by the Father of Chemistry, HERMES, to ODYSSEUS, as an antidote to the poisons of CIRCE'.[14] A reference to 'saltpetre', potassium nitrate, is amplified by a note that the word means 'rock salt' and that this is itself a 'reminder that in bygone days chemists have found it very difficult to distinguish between substances of similar appearance' (p. 216). Elsewhere (p. 9), the reader is told that, in France, nitrogen is called azote (a name that indicates that the gas will not support combustion) and that the element cobalt is supposed to get its name from the German *Kobold*, a mischievous subterranean gnome that haunted the mines from which the ore was extracted (p. 508). All these references also appear in the 1952 publication, although the pagination is slightly different.

Holmyard's output as an author of school textbooks was not restricted to chemistry. *Science: An Introductory Book* was published in 1926, *General Science* appeared the following year and a three-volume series (*Physics/Chemistry/Biology for Beginners*) was published in 1930 (Holmyard 1930a, b, c). Intended for the first two years of secondary schooling, a reviewer of the series in *The School Science Review* welcomed it as 'three very excellent books', adding that it was 'a pleasure to meet school textbooks which are not pervaded by an atmosphere of public examination syllabuses' (SSR 1930, p. 190). In the 1930s, Holmyard also co-authored *Electricity and Magnetism for Beginners* (Badcock and Holmyard 1931); *Heat, Light and Sound for Beginners*; and *Mechanics for Beginners* (Barraclough and Holmyard 1931), published as part of a Modern Science Series. Badcock and Barraclough were two of Holmyard's colleagues at Clifton and he collaborated with a third Clifton colleague to write *Elementary Botany* (Graham and Holmyard 1935). He also edited J. A. Thomson's two-volume *Biology for Everyman* (Thomson and Holmyard 1934) and was one of the editors of an eight-volume *History of Technology*, published between 1954 and 1984 (Singer et al. 1954–84; see also Holmyard 1946).

Why were so many of Holmyard's historicised school chemistry textbooks such successful[15] publishing ventures? To some extent, his success stemmed from a

---

[14] Holmyard believed strongly in the merits of a classical education, encouraging boys to study classics before taking up chemistry in the upper school, and he made frequent use of classical analogies, e.g. the 'passion of Hydrogen and Oxygen for one another causes as much trouble in the chemical world as that of Paris for Helen did in ancient Troy'.

[15] Although Holmyard's textbooks seem always to have been reviewed very favourably, reviewers were usually able to identify some matters that needed attention. Almost all of these related to a

clarity of style that allowed him to express complex ideas in ways that young pupils could readily access. One reviewer of his *Elementary Chemistry* described it as 'written in English which any boy can understand - the sort…which one seldom finds in a textbook' (SSR 1925b, p. 140). Recalling his schooldays at the Crypt School in Gloucester, Keith Francis, a school teacher who graduated in physics from Cambridge in 1956, described Holmyard as having a 'spicy' literary style that 'grabbed me' (Francis 2004, p. 15).[16] Holmyard's obituarist in *Nature* judged that 'many students' of the journal 'must owe their introduction to chemistry' to his inorganic and organic chemistry textbooks which presented the basic facts of chemistry 'as an experimental science, relating them to general principles in a way which gives them significance and interest' (Partington 1959, p. 1360).

In addition, although the illustrations in Holmyard's books were in black and white rather than colour, they were always carefully chosen, well related to the narrative and often appeared for the first time in texts intended for school use.

> The plates and pictures are delightful and make the book very attractive; after seeing page 73 all our boys will want to get out and collect marsh gas –which is as it should be! (*idem.*)

> The illustrations are admirable and almost all unfamiliar. (SSR 1933, p. 126)

His textbooks also had a readily discernible structure that enabled information to be easily located and, if necessary, retrieved for homework or revision purposes. This became increasingly important as the numbers of candidates attending grant-aided secondary schools and entered for public examinations both increased in the interwar years. The number of pupils attending grant-aided secondary schools increased from 269,887 in 1919 to 470,003 by 1938, although by no means all of these completed their secondary schooling.[17] Aided by grants from the Board of Education, the number of 'advanced', i.e. sixth form, courses in science also increased. By 1938, physics and chemistry each accounted for just under one third of all entries for the Higher School Certificate Examination taken at the end of secondary schooling; the biological sciences (botany, zoology and biology) had yet to establish a secure place in the curriculum of many secondary schools, especially those for boys (Jenkins 1979).

The long publishing history of many of Holmyard's textbooks was also facilitated by the fact that school examination syllabuses in chemistry and physics in England

---

few typographical/proof reading errors or other relatively minor defects. One notable exception was a reviewer of Holmyard's *A Junior Chemistry* (Holmyard 1933). While writing that the book would be 'read with delight by any boy or girl without any need for external stimulus', the reviewer wondered whether 'a boy of 14…may be aggravated by the use of an appeal in the second person singular and of exclamation marks' (SSR 1933, p. 126).

[16] Francis also describes Philbrick and Holmyard's *Theoretical and Inorganic Chemistry* as a 'treasure' and recalls how, as a 13-year-old pupil, it enabled him to know everything that Tarzan [the nickname of his chemistry teacher!] wanted to teach him (Francis 2004, p. 15).

[17] These figures need to be set alongside the much larger number of pupils who attended public elementary schools in England and Wales: 5,933,458 in 1920–1921 and 5,087, 485 in 1937–1938. The division between elementary and secondary education reflected significant differences in social class. It was only after the Education Act of 1944 that all pupils passed from a primary to some form of secondary schooling (grammar, secondary modern or technical).

underwent astonishingly little change between 1918 and the curriculum reform movement of the 1960s. Save for the replacement of Imperial units by the centimetre-gramme-second (cgs) system, examination questions in physics set in the 1920s first appeared in much the same form over a generation later. In chemistry, candidates continued to be examined on their detailed knowledge of the manufacture, preparation and properties of the elements and their compounds with questions following a standard format year after year (Jenkins 1979, p. 293). In Bassey's judgement, Ordinary-level chemistry texts had followed 'one familiar and well-worn path' which, by 1960, had become 'a rut rather than a highway' (Bassey 1960, p. 14).[18] There is little doubt that this judgement can be applied, although to a lesser extent, to school texts in physics and biology and those intended for more senior secondary school students.

Holmyard was also able to call upon his experience both as a teacher and as an examiner for the former Northern Universities Joint Matriculation Board (NUJMB). Indeed, the preface to his *A Higher School Certificate Inorganic Chemistry* informs the reader that 'the allotment of space to individual topics is roughly in proportion to the frequency with which these topics appear in the examination papers', although he is very careful to make clear that more is needed in any textbook that 'aspires to do something more than cram', an aspiration that one reviewer readily acknowledged.

> The author is no Polyphemus and his other eye has watched the cultural aspect of chemistry to prevent the work from degenerating into a mere cram book. (*J. Chem. Ind.* 1940, p. 50)

Holmyard's footnotes and historical commentaries were an integral part of this 'something more', and it would be a serious error to dismiss them as idiosyncrasies or regard them as mere ornaments intended to display the author's undoubted erudition. Footnotes and comments they may be, but they formed part of a coherent and distinctive volume that enlivened, enriched and contextualised school chemistry and its nomenclature, then far from standardised, in ways that have not been matched. No one reading Holmyard's texts can avoid learning something of the many roles that chemistry has played and continues to play in recorded history. Reading them today indicates just how much has been lost from chemical education.

74.5 Historical Approaches: The Wider Context

Holmyard was by no means the first to argue for a historical approach to the teaching of school science nor was he alone among his contemporaries in writing historicized chemistry textbooks (e.g. Partington, Cochrane, Lowry).[19] As long ago as 1855, the

---

[18] Bassey used Holmyard's *Elementary Chemistry* as 'the standard treatment' with which to compare other school chemistry texts in print at the time of his survey.

[19] J. A. Cochrane's *Readable School Physics* (1923) and his *School History of Science* (1925) were highly successful publications, both of which have recently been made available once again. The former was part of a Natural Science Series published by Bell and edited by Holmyard. J. R. Partington, professor of chemistry at the University of London, had studied with Nernst and

president of the British Association for the Advancement of Science, the Duke of Argyll, told his audience in Glasgow that what was wanted in the 'teaching of the young, is not so much the mere results, as the *methods* and, above all, the *history of science'* (BAAS 1856, p. *lxxxiii*). Nor was Holmyard to be the last: over a century and a half later, the history of science featured in a national curriculum introduced for the first time in England (DES 1989). Even more recently, the European Commission has argued that 'a renewed pedagogy' which presents 'the processes and methods of science together with its products' is essential for the 'Future of Europe' (EC 2007, p. 16).

Among Holmyard's contemporaries, Edgar Fahs Smith (1854–1928) in the USA, chemist and author of biographies of several American chemists (Smith 1914), was said to be 'fond of theories in an historical way, but used the luxury of their downfall by experimental observation to illustrate the fallacy of theories'. This quotation is cited in Fowles who attributes to Smith the expression 'Facts remain, theories may change overnight'(Fowles *op.cit.,* pp. 516–7). Among Fahs's successors in the USA, Conant's *Case Histories* (Conant et al. 1957; see also Conant 1947), the *Harvard Project Physics*(1970), the *National Science Education Standards* (NRC 1996), *Benchmarks for Science Literacy* (AAAS 1993), the textbooks of Taylor (1941/1959) and Rogers (1961) and initiatives such as McComas's use of historical examples to illustrate key aspects of the nature of science (McComas 2008) all testify to the enduring appeal of the history of science as a pedagogical tool. Given the profound changes that have taken place in science, philosophy, psychology and society since science was first schooled in the mid-nineteenth century, this widespread and enduring desire to call upon the history of science to illustrate something of the 'nature of science' calls for some comment.

Holmyard's historical approach to teaching science should not be equated with simply incorporating biographical or other elements of the history of science within school science curricula, an accommodation with which many science teachers would have felt much more comfortable and which seems to have met with more success. However, an inadequate knowledge of the history of science and its attendant risk of an unhelpfully Whiggish approach to history were problems common to

---

was the author of advanced chemistry textbooks, of *A Short History of Chemistry* (1937) and of a four-volume history of chemistry Partington (1961–4). His elementary text, *Everyday Chemistry*, is divided into three parts of which the first is entitled 'Historical and Theory' (Partington 1929). A reviewer of Partington's *A College Course of Inorganic Chemistry* (1939) warned his readers that 'Professor Partington has written so many books that have been distinguished by their lucidity and accuracy that a reviewer reading a new book by him begins by being prejudiced in his favour' (*J. Chem. Ind.* (1939) 58 (44), p. 974). A similar comment might well have been made of Holmyard. In 1965, the year of his death, Partington was awarded the George Sarton medal. Thomas Martin Lowry, FRS, worked with H.E. Armstrong from 1896 to 1913 and later became professor of physical chemistry at Cambridge. With J.M. Brønsted, Lowry introduced a new and broader definition of acids and bases. Lowry's generously illustrated *Historical Introduction to Chemistry*, first published in 1915, presents 'a historical account of the more important facts and theories of chemistry, as these disclosed themselves to the original workers' (Lowry 1915, preface). Although perhaps more appropriate for teachers than school students, the book is a further indication of the steady stream of educators who have regarded the history of science as an important component of science education.

both. In addition, as Brush was to suggest later (Brush 1974), introducing students to the history of science might not accord with a desired canonical account of scientific discovery. Even so, whether as a pedagogical approach or as a component of a school science curriculum, the history of science is a striking feature of the history of school science education. Why is this?

Part of the answer may lie in the fact that renewed calls to attend to the history of science have often coincided with a perception that the school science curriculum is in difficulty or facing challenges that prompt a need for reform. As noted above, the desire in the interwar years to 'humanise'[20] school science by teaching the history of science owed much to the feeling that in making possible the unparalleled slaughter of the First World War, science – and chemistry in particular – had lost a sense of moral purpose that it urgently needed to regain. The emphasis on science in Germany came to be seen as having led not only to economic prosperity but also to the moral collapse responsible for the war in which the Allies had been engaged. Restoring that sense of purpose seemed to require reform of the school science curriculum and the history of science pointed a way forward.

> …the teaching of science must be vivified by a development of its human interest, side by side with its material and mechanical aspects… [and] it must never be divorced from those literary and historical studies that touch most naturally the heart and the hopes of mankind. (Natural Science in Education 1918, para. 3)

The contrast with the aftermath of the Second World War is striking.[21] Despite the advent of nuclear war, science and technology emerged from that war with their prestige greatly enhanced. The consequent demand for reform of school science education was governed by the urgent need to increase greatly the supply of qualified scientific and technological personnel, both for civilian and, at the height of the Cold War, military purposes (Rudolph 2002). The history of science was seen as, at best, only marginally relevant to achieving this goal. Supported by a psychology that favoured 'learning by discovery', the emphasis in what became a global movement for science curriculum reform was captured by Bruner's claim that 'a schoolboy learning physics *is* a physicist' (Bruner 1960, p. 14), a claim repeated by Harlen with respect to primary education in the UK almost forty years later: '*Learning science*

---

[20] For a historical perspective on the humanist critique of the place of science in the school curriculum, see Donnelly (2002), Donnelly (2004) and Donnelly and Ryder (2011). See also Mayer (2005). For a discussion of science as humanism in Denmark in the 1950s, see Lynning (2007). It is worth noting that there have been frequent calls to 'humanise' other abstract disciplines, e.g. economics (Solterer 1972) and mathematics (Guting 2006). Indeed the word 'humanising' has perhaps acquired something of an Alice in Wonderland quality, writers taking it to mean what they wish it to mean. In 1924, the author of an article in *The North American Review* asked 'By the plain light of noon, what is implied in "humanizing" science?' (Glaser 1924, p. 230). Today, as searching the Web reveals, the science education literature is replete with references to humanising school science education, offering a variety of rationales and strategies for bringing it about. See, for example, Watts and Bentley (1994), Kipnis (1998), and Clough (2009).

[21] However, at least one prominent science educator felt much the same about the role that science was also playing in the Second World War. See Westaway's *Science in the Dock: Guilty of Not Guilty?* (1942).

and *doing science* proceed in the same way' (Harlen 1996, p. 5). In the USA, students following *ChemStudy* courses were promised that they would 'see the nature of science' by engaging in scientific activity' and thereby to 'some extent' become scientists themselves (Pimentel 1963, p.1 and preface). In the UK, despite an assertion[22] by the Science Masters' Association and the Association of Women Science Teachers that science was an 'active humanity' (SMA 1961, p. 5), canonical science was to be presented in a way that enabled students to 'think in the way practising scientists do' (Halliwell 1966, p. 242). Much that followed, such as *Process Science* and *Science in Process,* also sought to introduce students to the nature of science by involving them in suitable practical, laboratory-based exercises designed to encourage the acquisition of those allegedly discrete skills and processes (communicating, interpreting, observing, planning investigations etc.) that in sum enabled them to be good at science (Coles 1989, pp. 4–5).

During the 1960s, it gradually became clear, both in the UK and the USA, that the large-scale efforts to reform school science education had not succeeded in increasing, or in some cases even stemming, the numbers of young people wishing to study the physical sciences, especially physics, beyond compulsory schooling. In England, the Council for Scientific Policy set up a committee, chaired by the eminent chemist Frederick Dainton,[23] to 'examine the flow of candidates in science and technology into higher education' (Council for Scientific Policy 1968). Although the committee's conclusion that there was a 'swing from science' in schools was soon challenged (e.g. McPhemon 1969), it received widespread publicity (e.g. AAAS 1968) and prompted a wide range of research studies of possible causes of the 'swing' away from what have become known as the STEM subjects. Such causes remain the focus of ongoing investigation in many countries (Sneider 2011). In the USA, it was clear as early as 1963 that the PSSC course had attracted 'only about 4 % of the two and a half million senior students in high school, and the total fraction taking *any* physics course was under 20 %, and relatively shrinking' (Holton 2001, p. 2).Once again, the history of science was seen as one way of easing, if not overcoming, the problem. Holton, in a review of the *Harvard Project Physics* course, has recalled how he and others were invited to a meeting by the National Science Foundation at which they were asked

> who would come to the aid of the country? For in those days it was thought without more science-literate students the Russians might get us. (*idem.*)

Holton's answer eventually led him to become the principal investigator of *Harvard Project Physics* and thereby to develop a 'humanistic, historically oriented course for schools' that presented physics, as in his original text (Holton 1952), 'not

---

[22] For the Science Masters' Association, if more emphasis were placed upon the cultural and humanistic sides of science education, this might not only lead more young people to study science but encourage them to favour science teaching as a career (SMA 1957).

[23] Dainton, speaking in 1971, used the memorable phrase 'voluntarily withdrawn from human contact; disassociating himself from personal and societal problems… a man who is "objective" to an objectionable degree', to describe how scientists were widely perceived at the time (Dainton 1971, p. 18).

just as one damned thing after another, but a coherent story of the result of the thoughts and work of living beings' (Holton 2001, p. 2). The outcome was the sort of course that Holmyard would have welcomed, especially the illustrations taken from seminal documents in the history of science that appeared in the course book. Interestingly, the initial reaction of the National Science Foundation to the fact that course wasn't going to be pure physics was one of 'horror'! By the time the final edition of the book was published in 1970, there was significant evidence that it was having an impact on the numbers of students studying physics at high school and college. As many as 300,000 students per year were studying some or all of the course materials and the percentage taking physics, particularly among women students, had increased markedly, 'with some 20 % of all high school students taking *Project Physics,* and in use also in some colleges' (Holton 2001, p. 4).

Although further growth of *Project Physics* in schools (the reference to Harvard in the title was abandoned amid concerns over 'elitism!') fell foul of the phasing out of sections of federal support for science education in the 1970s, especially funds for science teacher education, it acquired a new lease of life when the USA once again sought to reform school science education, this time by prioritising the need for a scientifically literate citizenry, although a number of other factors were involved, e.g. the demand from teachers for a revised and updated version of the project materials and the need to improve the understanding of physics on the part of a new generation of physics teachers. As noted above, the AAAS *Benchmarks for Science Literacy* (AAAS 1993) and the *National Science Education Standards* (NRC 1996) both attached importance to the history of science. The former included an entire chapter devoted to 'Historical perspectives' (chapter 10), while the latter advised standards for the history of science from K4–12. The revised edition of the earlier text, published in 2002 under the title *Understanding Physics* (Cassidy et al. 2002), was described by Holton as the 'completion of a great circle, spanning four decades, from the first draft in 1962…through the slough of the early 1980s and now on to the rising of the new Phoenix' (Holton 2001, p. 6).

That circle offers an interesting example of how a federally funded history of science initiative in the USA, initially prompted by manpower and defence concerns, came to be recast and called in aid of the perceived national need to promote science for all and enhance the general level of scientific literacy. There are some parallels here with the UK, not least in the political anxiety about scientific literacy and the levels of public understanding of science, although the picture is complicated by profound differences in the education systems of the two countries and, more particularly, by the development of a non-selective system of secondary schooling and the subsequent introduction of a statutory national curriculum in England and Wales in 1989. By requiring all students to study science from the age of 5 to 16, it was hoped that this would in due course both promote scientific literacy and develop a larger cohort of students choosing to study science, especially physical science, beyond compulsory schooling. The UK government clearly saw compulsion as a more effective policy initiative than the large-scale curriculum reform of a generation earlier. Despite this, the initial version of the national curriculum included a component (known as an attainment target) that drew upon contemporary views from both the history and the sociology of science. Its inclusion prompted the editor of the *British Journal for the History of Science* to offer the following somewhat slightly anxious comment.

> The overriding statement of intent…is one that might be welcomed by the most radical exponent of the view that scientific knowledge is shaped by social, economic and political context. (BJHS 1990, pp. 1–2)

In the event, the first version of the national curriculum almost immediately proved unworkable and very little of the history of science survived into the revised statutory science curriculum introduced in 1991,or indeed into the several revisions that have taken place since (Donnelly et al. 1996;Donnelly and Jenkins 2001). It has largely been left to individuals and non-governmental sources to take initiatives to promote the history of science in science education.[24]

Advocacy of the history of science in aid of science curriculum reform may also owe much to historians of science themselves. Holmyard and Holton stand as two obvious examples, from different generations and countries, of scholars in the history of science giving attention to the form and content of school science curricula. Their pedagogical interest, however, is part of a much longer-standing and wider interest among their fellow professionals that has been well described by Brock (1989) and Sherratt (1980). There has been an equally long-standing interest on the part of many school science teachers in the history of science and in the contribution that it might make to their teaching. Practising and former science teachers were among the founding membership of the British Society for the History of Science in 1946 and their professional association, The Science Masters' Association and its successor from 1963 onwards, the Association for Science Education, collaborated with the BSHS in a variety of curriculum and policy initiatives (Brock 1989, p. 33 *et seq.*). In addition, history of science books was regularly reviewed in *The School Science Review* and the titles included in the suggested list of *Science Books for a School Library* issued from time to time as a supplement to the association's journal.

The motives of both organisations and their members in promoting collaboration are, as always, historically contingent. Closer involvement with the work of the schools has had the advantage of bringing the history of science to the attention of teachers and students who, in turn, were able to take advantage of historical expertise to their mutual benefit. This no doubt was an important consideration, especially in its early years, for the Department of the History and Methods of Science at University College London which directed its efforts 'chiefly at science teachers and thus at secondary education' (Mayer 1999, p. 233). On some occasions, notably in the interwar years, the rhetoric underpinning this mutual interest related strongly to humanising science teaching and to reasserting the cultural value of science. At other times, the language has been that of bridging the 'two cultures' identified by Snow in his 1959 Rede lectures (Snow 1959, 1964), although the

---

[24] For example, the *Perspectives on Science* course developed at Rugby School in Warwickshire (www1.edexcel.org.uk/Project/POS-Briefing.doc) and the Public Understanding of Science course developed at the University of York (http://www.nuffieldfoundation.org/science-public-understanding), both accessed 30 January 2012.

emphasis upon science as a ‘humanity’ has never been lost (Council for Scientific Policy *op. cit.,* para. 181). Most recently, the history of science has been cast as an element of the ‘nature of science’ which has come to figure so prominently in science curricula across the world, while pedagogy (McComas 1998) and the form and practice of scientific research have become fields of scholarly academic interest to historians of science (Kaiser 2005). That is perhaps another ‘great circle’ that is in the process of being completed.

74.6 Conclusion

How might Holmyard’s work be viewed in the light of the changes outlined above? Among his alchemical studies, his work on Geber[25] was of seminal importance, and like all sound scholarship, his research as a historian of science has provided a platform upon which other scholars have been able to build. J. R. Partington, himself a distinguished historian of chemistry and textbook author, judged that Holmyard’s alchemical studies were of ‘permanent value’. Noting that alchemists and early chemists believed that metals were composed of mercury and sulphur, Partington drew particular attention to Holmyard’s finding that this theory, promoted by Geber, derived from a statement in Aristotle’s ‘Meteorology’ (Partington 1959). Holmyard’s 1957 book, *Alchemy,* was published in several languages, reprinted in 1990 and remains an important and readable survey of the subject. His obituarist in *Ambix* offers a useful overview of Holmyard’s alchemical studies and comments that he added to ‘our knowledge of this subject…its great names, its theories, its experiments and its apparatus’. His conclusion is that Holmyard brought about ‘a greater interest in and an improved understanding and appreciation of the work and writings… of …Muslim chemists in general’ (McKie 1960, p. 5).

Although Holmyard’s school chemistry textbooks were written for syllabuses and examinations that differ greatly from those confronting students in the early years of the twenty-first century, they remain an important model for any author wishing to present chemistry, not simply as a discipline, but as an integral part of a wider cultural history. Reading some of his textbooks helps the reader understand that interest in the behaviour of materials and the desire to understand how they may be changed from one to another is at least as old as recorded history. At the end of a chapter entitled ‘How Chemistry Arose’, Holmyard invites the reader of his *Elementary Chemistry* to answer questions such as the following:

---

[25] Geber is the Latin equivalent of Jâbir, and the name was used by the author of an influential series of alchemical texts in the fourteenth and fifteenth centuries. It seems likely that this Latinised version of the name was adopted by a Western writer in order to heighten the authority of his own work: Holmyard’s ‘likely guess’ (Holmyard 1957, p. 134) was that these later mediaeval works were written by a European scholar, possibly in Moorish Spain. Holmyard was able to identify the eighth-century alchemist Jâbir Ibn Hayyân who held a court appointment under the Caliph Harun al-Rashid. A lengthy examination of the ‘Geber problem’ is available at www.history-science-technology.com.

> Mention some of the chemical facts and processes known to the Ancient Egyptians.
>
> Explain how it was that the Muslims were able to establish chemistry on a sound basis.
>
> Who was Paracelsus? What service did he render to chemistry?

Anyone who follows the historical journey that Holmyard sets out so skilfully in his texts will therefore travel with him to China, India and Arabia as well as within Europe, glimpsing other languages and cultures on the way and learning that it is all too humanly possible to take a wrong turning while firmly believing it is the way forward. The journey that he offered was much less familiar in the first few decades of the twentieth century than is the case today when societies have become much more multicultural and scholars more aware of non-Western contributions to the development of science.

Although Holmyard's evolutionary approach found limited favour, his advocacy did much to draw attention to the contribution that the history of science could make to school science education and to encourage teachers to incorporate historical components within their teaching. In doing so, the various attempts to 'humanise' school science teaching presented challenges and problems that have a contemporary international relevance as attempts are made to accommodate the history of science within the movement to promote the teaching of the 'nature of science'. As experience with *Harvard Project Physics* confirmed, addressing and overcoming these challenges and problems requires a substantial investment in science teachers' professional development that is grounded in collaboration between those whose scholarly expertise lies in the history of science and those teaching science in schools. That can succeed only if there is agreement about the contribution that the history of science can legitimately make to the science curriculum and if science teachers enable their students to think historically as well as scientifically. Fortunately, the form and content of that contribution are now matters not only for lively but well-informed debate but also for science curriculum development (e.g. Holton 2003; Matthews 1994/2014, 2009; Kokkotas et al. 2009).

Edgar W. Jenkins is Emeritus Professor of Science Education Policy at the University of Leeds where he was Head of the School of Education (1980–1984 and 1991–1995) and Director of the Centre for Studies in Science and Mathematics Education (1997–2000). From 1984 to 1997, he edited the research review journal *Studies in Science Education*. His principal books include *From Armstrong to Nuffield* (1979), *Technological Revolution?* (1986), *Inarticulate Science?* (1993), *Investigations by Order* (1996), *From Steps to Stages* (1998), *Learning from Others* (2000) and *Science Education, Policy, Professionalism and Change* (2001). He has recently coedited a volume published to mark the fiftieth anniversary of the founding of the Association for Science Education in 1963.

Chapter 75
John Dewey and Science Education

James Scott Johnston

75.1 Introduction

John Dewey is perhaps the most well-known philosopher of education of the twentieth century. His output was prodigious and he is distinctive for placing education at the centre of important philosophical discussions. Dewey has in addition a series of attentive accounts on traditionally philosophical topics, such as theory of knowledge, meaning, experience, reality, ethics, political and social theory and aesthetics—all of which count education as important. Dewey's most important educational treatises include *The School and Society* (1899), *How We Think* (1910), *Democracy and Education* (1916) and *Experience and Education* (1938), and the former three were in use as textbooks for hundreds of thousands of teachers in teacher-training programmes in America over several decades in the first half of the twentieth century. Dewey continues to have an influence on teacher training and, important for our purposes here, science education.

In this chapter, I will concentrate on three themes: Dewey's theory of experience and the role of reflection or thought, Dewey's theory of inquiry (scientific method) and Dewey's claims for science education. The three are interrelated and discussing Dewey's claims for science education presupposes discussing his theories of experience, reflection and inquiry. I will follow with a brief discussion of recent developments in science education that have invoked and used Dewey: constructivism and science education, science education and models of inquiry in the curriculum, and the teaching of science. I will finish the chapter with my assessment of the scholarship on Dewey and science education.

75.2 Brief Biographical Sketch

John Dewey was born in Burlington, Vermont, on April 22, 1859. He grew up in Burlington and attended the University of Vermont. Dewey taught high school for 2 years in Oil City, Pennsylvania, and a further half-year in Charlotte, Vermont, prior to attending graduate study in philosophy at newly minted Johns Hopkins University under advisor, George Sylvester Morris. Having graduated in 1884, Dewey began his university career at the University of Michigan (1884–1888; 1890–1893) and the University of Minnesota (1888–1889), followed by the University of Chicago (1894–1903) (where he ran the famed laboratory school) and, finally, Columbia University in New York (1904–1927) where, in addition to an appointment as professor of philosophy, he was also professor of pedagogy at Teachers College. Dewey married Alice Chipman in 1886, and together, they raised seven children, though two died at very young ages. Dewey would also adopt two children. Dewey travelled and lectured extensively, especially in later life, most famously in Russia, China, Turkey and Mexico. After retirement from active teaching in 1930, his already prodigious output increased; when he died in 1952 in New York City at the age of 92, he had published some 47 books and 1,500 articles.

75.3 Dewey's Philosophical Project

Dewey's philosophical project was to aid in the bringing of the attitudes, criticisms, methods and results of philosophers to bear on practical concerns (Middle Works (MW) 10, 47). As well, it was to make philosophy and philosophers a valued enterprise for the task of democratically associated living (MW 9, 91). Dewey famously claimed that philosophy was the 'criticism of criticisms' and that this ought to be put to work in social and cultural transformation (Later Works (LW) 1, 309). Central to his philosophical project was the 'method of intelligence' (MW 10, 45), variously understood as 'inquiry', 'problem-solving', 'how we think' and 'scientific method'. Though Dewey sometimes distinguished between these (largely on the basis of context), they were coterminous in the project of getting philosophy (and other disciplines) to bear on what Dewey considered 'the problems of men' (MW 10, 48).

75.4 Dewey's Educational Project

Formal education has many important aims and functions, but in terms of science and science education, this one stands out: education was for Dewey the chief means with which to inculcate in the species the problem-solving method of intelligence needed to overcome extant social problems. Having said this, other aims and functions of education are coterminous with the development of the method of intelligence. Social and cultural transmission of past matters of fact and the techniques to solve what Dewey refers to as ‘problematic situations’ (LW 12, 112) is one example. Growth, which is the natural end of individuals and the human species (and is sometimes said by Dewey to be *the* end of education (e.g. MW 9, 47–49; LW 13, 19)), is another. To utilize the method of intelligence is to draw on past matters of fact and techniques, and to grow is to transform oneself and one’s environment in accordance with a set of problem-solving methods, as I will discuss further in the section on inquiry.

75.5 Deweyan Inquiry

Dewey discusses inquiry variously, and in several key texts and articles. What I will do here is provide a summary exegesis of his various claims, beginning with the relation between experience and inquiry, followed by a discussion of Dewey’s claims for the stages of thought, the role of specifically scientific thinking in inquiry and the role of scientific inquiry in the social sciences.

75.5.1 The Foundation of Inquiry: Experience

Dewey rejects the empiricist notion that we assemble bits of information through our sense-perceptive faculties and reorder them as ideas in the mind. He also rejects the rationalist notion that ideas are innate or otherwise necessary and pure principles that bear down on our sense-perceptive apparatus to fashion objects of the mind. What Dewey offers is an account of experience in which we exist in a world of what he would call ‘brute facts’ and ‘thats’ (MW 3, 164), a world that is first felt rather than cognized (LW 5, 249). What we experience as felt is a whole, not an object. Nor is a felt whole a mere feeling. It is rather that the felt whole is what we experience—as an immediate quality. The human organism exists in a qualitative state, and when she experiences, she does so qualitatively, through feeling. Feeling, in turn, is dependent on generic ‘traits of existence’, which arise out of every encounter of the human organism with the world (LW 1, 308). These traits are ‘qualitative individuality and constant relations, contingency and need, movement and arrest…’ (LW 1, 308). Dewey adds to this list ‘rhythm and regularity’ and ‘our constant sense of things as belonging or not belonging, of relevancy…’ (LW 10, 198). Not every experience will have these traits as rich and defined as others. Most experiences are ‘mundane’; they evince some traits of existence but not of sufficient quality to be notable. Those experiences that do, Dewey considers to be consummatory. A consummatory experience is one in which the experience is felt and taken as a qualitative whole, a unity and a totality.

Inquiry begins and ends in experience. Experience in turn supplies inquiry with the situations or events from which inquiry forms what Dewey calls ‘thought’ or ‘reflection’. In the attempt to reproduce the event or situation that led to the consummatory experience, the human organism will be poised to attempt reflection. Dewey in one place calls this a ‘judgment of appreciation’ (LW 12, 177–178). Successful reflection will eventually lead to the isolation of the factors involved in the event, together with their control and prediction for further events. However, Dewey cautions we must not confuse the resultant appreciation which is felt, with the operations that bring the material into harmony. To do so is to hypostatize feeling into generalizations (LW 12, 179). Such, historically, is the case with the good, the true, the beautiful and other ‘absolutes’.

Dewey discusses the way in which we are induced to reflect upon our experiences. This occurs when we have and undergo an unsatisfying experience when we expect a satisfying or otherwise unproblematic one; an experience that has a paucity or (as Dewey sometimes says) imbalance of the traits of existence and that does not lead to a qualitative whole. In the context of inquiry, Dewey calls the event or situation that concludes in an unsatisfying experience a ‘felt difficulty’ or ‘indeterminate situation’ (MW 6, 237; LW 12, 108). We then undertake inquiry to ‘determine’ the situation. When we are able to order and control the qualities or traits of the experience of an indeterminate situation, we form an experience that is complete, satisfying and qualitatively whole. Indeed, this is the basis of Dewey’s most famous definition of inquiry: ‘Inquiry is the controlled or directed transformation of an indeterminate situation into one that is so determinate in its constituent distinctions and relations as to convert the elements of the original situation into a unified whole’ (LW 12, 108).

75.5.2 The Rise of Science and Scientific Thinking

The self-awareness of the role of reflection and its various techniques and stages obviously did not arise at once: it was the result of thousands of years of investigation (much of it haphazard or misleading) into the forces of nature, the constitution of material objects of use (technologies) and the increasing role of methods in ascertaining instrumental results. For much of this history, the establishment of methods and principles of science fell to philosophy, and Dewey characteristically concentrates his examination of the history of the rise of science and scientific thinking to developments within philosophy. Dewey’s thesis is that a previously stable set of affairs (both individually and species wide) is upset, unsettled or otherwise rendered dubious. The tension leading to instability is the impetus for further questioning, investigation and inquiry, and this leads (if successful) to a readjustment, a resettlement. We understand this through recourse to a historical/developmental and evolutionary account of the rise of science—what Dewey calls ‘the genetic method’ (MW 1, 150; MW 2, 300–301). We have here the pattern Dewey would use in his discussion of inquiry generally—a pattern made famous in his discussion of the stages of thought in the two editions of *How We Think* (1910: 1932) and in his definition of inquiry as the settlement of an unsettled or indeterminate situation in *Logic*: *the Theory of Inquiry* (1938a).

Dewey's concentrated attention on the rise of scientific thinking through history is best exemplified in the early, extended essay, 'Some Stages in Logical Thought' (1903) together with his book, *Reconstruction in Philosophy* (1920). In his essay, Dewey notes four stages in the development of logical thinking: the magical thinking of the earliest societies, the dawning awareness of the need for method in ancient civilizations, the isolation and abstraction of principles and standards in ancient Greek (Hellenistic) societies and, finally, the rise of a scientific method in the seventeenth century and beyond (MW 1, 172–173). In *Reconstruction in Philosophy*, Dewey alters his stage account of the rise of scientific thinking, noting specifically religious, metaphysical and scientific eras. In the religious era, Dewey claims, 'Savage man recalled yesterday's struggle with an animal not in order to study in a scientific way the qualities of an animal or for the sake of calculating how better to fight to-morrow, but to escape from the tedium of to-day by regaining the thrill of yesterday' (MW 12, 80). In the metaphysical era, 'The growth of positive knowledge and of the critical, inquiring spirit undermined those in their old form…' (MW 12, 89). What was left, according to Dewey, was to 'Develop a method of rational investigation and proof which should place the essential elements of traditional belief upon an unshakeable basis; develop a method of thought and knowledge which while purifying tradition should preserve its moral and social values unimpaired' (MW 12, 89–90). Finally, in the scientific era proper, the recognition of the genetic method—a method at once empirical, experiential, and scientific, historical and developmental—is the best assurance of producing practically valuable investigative results (MW 12, 93).

75.5.3 The Stages of Thought

In *How We Think* Dewey outlined and then expanded upon the stages of thought. Thought for Dewey is synonymous with reflection and inquiry: to think is to pass through the stages or phases of inquiry, from a problematic situation first felt, to the articulation of a problem, to the imagination of various anticipated outcomes, to the actual testing of the results using the various techniques and operations of isolation, ordering and control and prediction of phenomena, and finally, to the objective settlement and felt resolution or satisfaction of the original problematic situation. Thinking or inquiry is in other words, loosely circular. Here, I will spell out the various stages of thought. Dewey first gives a summary estimation of the five stages of the '…complete act of thought' (MW 6, 236). 'Upon examination, each instance [of genuine thought] reveals, more or less clearly, five logically distinct steps: (i) a felt difficulty; (ii) its location and definition; (iii) suggestion of positive solution; (iv) development by reasoning of the bearings of the suggestion; (v) further observation and experiment leading to its acceptance or rejection; that is, the conclusion of belief or disbelief' (MW 6, 236–237).

All genuine thought begins with a problematic situation, which for Dewey manifests as 'a felt difficulty' (MW 6, 237). This is the experiential basis of all thinking: a genuine inquiry can only take place if a genuine problem is found and established. Genuine problems are those that are felt, rather than abstracted or given ready-made to students, and Dewey hammers this point home in all of his educational writings. Felt difficulty may take various shapes. It may exist as 'emotional disturbance, as a more or less vague feeling of the unexpected, of something queer, strange, funny, or disconcerting' (MW 6, 238). Again however, what is important is that 'observations deliberately calculated to bring to light just what is the trouble, or to make clear the specific character of the problem' are undertaken (MW 6, 238).

In the second stage of thought, a clearly articulated problem is set forth. It is imperative that the problem be set forth consciously, because the techniques and operations of further stages of inquiry cannot be properly marshalled unless 'the trouble--the nature of the problem—has been thoroughly explored' (MW 6, 238). Failure to fully articulate the problem prior to engaging in experimentation with ideas and techniques of order and control of variables leads to frustration and dead ends—a sort of 'mission creep' that very often nets results for no particular problem, leading to failure for inquiry. As Dewey puts it, 'The essence of critical thinking is suspended judgment; and the essence of this suspense is inquiry to determine the nature of the problem *before* proceeding to attempts at its solution. This, more than any other thing, transforms mere inference into tested inference, suggested conclusions into proof' (MW 6, 238–239, emphasis mine).

The third stage Dewey calls 'suggestion'. Suggestion is that idea in which 'the perplexity…calls up something not present to the senses....Suggestion is at the very heart of inference; it involves going from what is present to something absent. Hence, it is more or less speculative, adventurous…The suggested perception so far as it is not accepted but only tentatively entertained constitutes an idea' (MW 6, 239). In this stage, what Dewey elsewhere calls a 'dramatic rehearsal', wherein we reconstruct the situation in thought and attempt to control for the various conditions, takes place (LW 10, 81–82). We are literally putting forth scenarios of possible outcomes, through varying the conditions of experimentation in thought. Here, tentative hypotheses are formed, thought through and passed or rejected according to the results of the thought experiment.

In the fourth stage of thought, more extensive inferential operation is carried out on those hypotheses that bear fruit in the earlier stage. In the earlier stage, we produce ideas—anticipated consequences of possible measures of control. 'As an idea is inferred from given fact [isolated from the situation], so reasoning sets out from an idea…' (MW 6, 239). Dewey continues

> …intimate and extensive observation has [its way] upon the original problem. Acceptance of the suggestion in its first form is prevented by looking into it more thoroughly. Conjectures that seem plausible at first sight are often found unfit or even absurd when their full consequences are traced out. Even when reasoning out the bearings of a supposition does not lead to rejection, it develops the idea into a form in which it is more apposite to the problem…The development of an idea through reasoning helps at least to supply the intervening or intermediate terms that link together into a consistent whole apparently discrepant extremes. (MW 6, 240)

Finally, the fifth stage or the conclusion of the 'complete act of thought' is 'some kind of *experimental corroboration*, or verification, of the conjectural idea…If we look and find present all the conditions demanded by the theory, and if we find the characteristic traits called for by rival alternatives to be lacking, the tendency to believe, to accept, is almost irresistible' (MW 6, 240). This is the conclusion to the problematic situation that initially led to the complete act of thought. That is, it is the *existential and qualitative termination* of the original problematic situation. Such terminations are existentially satisfying; they are the terminations of complete experiences—the sort that lead us to further investigation of the traits of existence of which they are constituted.

Dewey's stages of thought have sometimes been taken to be fixed steps that all thinkers must ascend in linear fashion. This is a mistaken interpretation of Dewey's complete act of thought. Dewey's stages are recursive: whenever one of the steps is engaged, the entire procedure is engaged. The recursive nature of the stages allow for the possibility that a complete act of thought occur even if the stages are not engaged in a linear manner. This allows for inquirers to enter the procedure without beginning at the first stage. Likewise, inquirers may exit the procedure prior to closure.

75.5.4 The Logic of Inquiry and Scientific Thinking

As discussed with reference to Dewey's *How We Think*, inquiry begins with a 'felt difficulty' (MW 6, 237); in *Logic: the Theory of Inquiry*, Dewey calls this an 'indeterminate situation' (LW 12, 108). It is an existential *and* felt difficulty that initiates an inquiry. However, a doubt does not carry us far: 'Organic interaction becomes inquiry when existential consequences are anticipated; when environing conditions are examined with reference to their potentialities; and when responsive activities are selected and ordered with reference to actualization of some of the potentialities, rather than others, in a "final existential situation," is inquiry properly speaking, begun' (LW 12, 111). A felt difficulty and indeterminate situation must be followed by a judgment for inquiry proper to be undertaken, a judgment that this situation is problematic (LW 12, 111–112).

Once a problem has been identified and a judgment rendered, the investigator searches out 'the constituents of a given situation which, as constituents, are settled' (LW 12, 112). We begin with these because they are settled (Dewey uses the example of the location of aisles and exists in a hypothetical fire at an assembly hall). The first step in the determination of a problem is to assemble these settled constituents in observation. Dewey says 'A possible relevant solution is then suggested by the determination of actual conditions which are secured by observation' (LW 12, 113). This solution, in turn, becomes an idea: anticipated consequence that is then carried out in practice (LW 12, 113). Observed facts are existential, in that they directly bear on the phenomena to be examined and/or tested; 'ideational subject matters' are of conceptual import. They concern other ideas and, specifically, the way these relate to one another (LW 12, 115). 'Ideas are operational in that they instigate and direct further operations of observation; they are proposals and plans for acting upon existing conditions to bring new facts to light and to organize all the selected facts into a coherent whole' (LW 12, 116). Existential facts and ideational subject matters are to be operationalized—tested out in an existential situation. Once the investigator has established a set of anticipated consequences, she tests these. This involves submitting ideas, as hypotheses, to evaluation on the basis of documented, existential results. Those hypotheses that 'pass the test' are confirmed; those that do not are jettisoned or reconstructed. The determination of a previously indeterminate situation—a situation that is felt, rather than abstracted—is the termination proper of inquiry.

This logic of inquiry applies equally to both common-sense and scientific inquiries. What distinguishes these is not the general method or pattern of inquiry. In both, we experiment; we feel an indeterminate situation; we articulate a problem; we develop anticipated consequences that are then formed into hypotheses; and we test these hypotheses in existential settings. Successful hypotheses are those that satisfy or otherwise determine an indeterminate situation. However, scientific inquiries differ from common-sense inquiries in a number of ways, some of more and some less import; the greatest difference, aside from the contexts in which scientific inquiries operate (often under laboratory or otherwise rigorously controlled environmental conditions), is the level of abstraction common to them (LW 12, 119). Common-sense inquiry and the conclusions it develops very often end in habit formation—a stock of habits is built up that we then use in solving our day-to-day or otherwise mundane problems. These habits are used as well in scientific inquiry; they provide the basis for further psychomotor (in the case of experimental manipulation of phenomena) and conceptual (in the case of objects under investigation) development. However, scientific inquiry must also avoid as much as possible becoming routine, as it then promotes the tendency to complacency, with the result that it overlooks crucial steps in experimentation or changes in phenomena. Even time- and experience-tested habits, including psychomotor skills and habits of thought, must be amenable to reconstruction in scientific inquiry.

It will do to examine some of the differing features of scientific inquiry. Here, I will look at four critical features of scientific inquiry that are self-consciously articulated in Dewey's *Logic: the Theory of Inquiry*: induction and deduction; the nature of propositions; theories, laws, and causality; and the role of mathematics and symbols. In terms of induction and deduction, Dewey tells us:

> Whatever else the scientific method is or is not, it is concerned with ascertaining the conjunctions of characteristic traits which descriptively determine kinds of relation to one another and the interrelations of characters which constitute abstract conceptions of wide applicability…The methods by which generalizations are arrived at have received the name "induction:" the methods by which already existing generalizations are employed have received the name "deduction...." Any account of scientific method must be capable of offering a coherent doctrine of the nature of induction and deduction and of their relations to one another, and the doctrine must accord with what takes place in actual scientific practice. (LW 12, 414)

With induction, we generalize a set of common characteristics, features or attributes. We take the conclusions from those generalizations and we infer what must be the case on the basis of these. Dewey calls the typical understanding of induction 'a psychological process' in which we are 'induced to apprehend universals which have been necessarily involved all the time in sense qualities and objects of empirical perception' (LW 12, 419). In calling the typical understanding of induction a 'psychological process', Dewey means to distinguish his understanding of it from this. Whereas induction is typically understood as the movement of particular to universal, this is heavily qualified by Dewey. 'Induction I take to be a movement from facts to meaning; deduction a development of meanings, an exhibition of implications, while I hold that the connection between fact and meaning is made only by an act in the ordinary physical sense of the word act, that is, by experiment involving movement of the body and change in surrounding conditions' (MW 13: 63). Elsewhere, Dewey says induction is an 'existential determination' (LW 12, 478); he also calls it a determination of meaning(s) (MW 13, 63). 'They make possible the operation of mathematical functions in deductive discourse' (LW 12, 478). In induction, we grasp what is general in the existential situation through examination of the sense qualities of that situation. Dewey calls the generalizations we develop in induction 'generic propositions' (LW 12, 253). These are propositions of kinds or classes. For example, the generalization of the class, 'liquid', consists in all of the like phenomenal attributes or characteristics that are grouped together under this rubric.

In induction, we have 'the complex of experimental operations by which antecedently existing conditions are so modified that data are obtained which indicate and test proposed modes of solution…' (LW 12, 423). Induction draws generalizations from the existing phenomena culled from the existential situation, which are then transformed into hypotheses that are actively brought to bear on the existing phenomena. This generalization, or generic proposition, then takes the form of an 'If-then' statement—what Dewey calls a 'universal conception' (LW 12, 253). In deduction, on the other hand, we make inferences on the basis of the conclusions of hypotheses we generate (LW 12, 422). There is thus 'a functional correspondence' between induction and deduction. 'The propositions which formulate data must, to satisfy the conditions of inquiry, be such as to determine a problem in the form that indicates a possible solution, which the hypothesis in which the latter is formulated must be such as operationally to provide the new data that fill out and order those previously obtained' (LW 12, 423).

As we have noted, if-then conceptions are claims about what will happen to phenomena under certain circumstances. Though they make claims on behalf of phenomena, they are symbolic, rather than referring to phenomena through existential operations. There is yet another class of propositions, a class that operates at a level of abstraction from these; Dewey calls these 'abstract conceptions' (LW 12, 258). Abstract conceptions help to regulate our universal conceptions. As such, these operate *deductively*, rather than inductively. An example will be helpful here. Consider the following if-then claim:

> I hypothesize that all liquids of the kind (an existential proposition) H_2O will evaporate (an abstract concept) over time T when the temperature (an abstract concept) rises above 100 C.

This hypothesis relies on abstract concepts: evaporation and temperature. Abstract concepts do rely on propositions for their content (e.g. we need to know what physical characteristics water consists of at a given temperature); however, the concept is itself an abstraction that relates only to other concepts (such as evaporation). As such, we can assess abstract concepts in one of two ways: the first is how well they hang together with other abstract concepts (such as the case with evaporation and temperature); the second is how well they help to generate working generic propositions (such as the hypothesis above). When we assess abstract concepts in terms of their ability to relate with one another, we are testing deductively.

Some conceptions are simple and concrete. These Dewey calls conventions. It is a convention, for example, not to place your open hand over a flame. Other conventions consist in particular propositions we use for carrying out experiments; for example, 'when attempting to ascertain the degree of evaporation of water in your experiment, be sure to fill the beaker half way for each attempt to maintain consistency across experiments'. However, though they are obviously important, conventions serve scientific inquiry only in the most mundane matters. Far more important for scientific inquiry are 'hypotheses and their meanings', which are 'developed in ordered discourse, observation and assemblage of data…'. Otherwise, 'observation and assemblage of data are carried on at random' (LW 12, 428). Dewey calls these clusters of hypotheses 'theories' (LW 12, 428). Theories rely on both abstract and generic conceptions and are formed when sets of these are banded together into a general claim about a range of phenomena. So, for example, the theory of natural selection encompasses both abstract concepts (various concepts relating to organelles, tissues and organs; various concepts of change across species; various environments), together with universal conceptions (hypotheses that must have been provable for a theory of natural selection to arise) and existential propositions (classes of fauna used in formulating universal conceptions). Laws concern interactions and interrelations that allow a 'comprehensive system of characters'. This in turn allows for 'ordered discourse' to be possible (LW 12, 439). So, for example, Boyle's Law, Charles's Law, Henry's Law and other gas laws are laws precisely because they concern the interactions of the content of the qualitative traits that determine the relations (say, increases or decreases in volume or pressure of gases, gases coming out of solution, etc.) under investigation.

Causation is a particular type of regularity. It is a means of instituting a single, unique, continuous history of events under investigation, rather than a claim for a fixed and final sequence of occurrences (LW 12, 440). For example, consider the law

> All liquids of the kind (an existential proposition) H_2O will evaporate (an abstract conception) over time T at temperature (abstract conception) X, if certain circumstances hold (result of universal conception).

The law denotes the events that take place when qualitative traits are so ordered through propositions and conceptions to render them amenable to a continuous historical series.

Dewey is keen, however, to insist on the absence of fixity or finality with respect to laws or causality. 'The fallacy vitiating the view that scientific laws are formulations of uniform unconditioned sequences of change arises from taking the function of the universal [if-then] proposition as if it were part of the structural content of the existential [classes] propositions' (LW 12, 439). If we mistake the universal conception (the proposition that tells us what we can expect under existential conditions) with the propositions of classes actually used in carrying out the particular experiment, we will mistake regularity under strict scientific conditions for a fixed and final regularity.

Finally, scientific inquiry uses symbols and mathematics to a far greater degree than other forms of inquiry. These are tools and have arisen out of the various attempts at solving existential problems (LW 12, 392). Symbols and mathematics operate at a realm distinct from the existential and the generic; indeed, they are wholly abstract. 'When, however, discourse is conducted exclusively with reference to satisfaction of its own logical conditions, or, as we say, for its own sake, the subject-matter is not only nonexistential in immediate reference but is itself formed on the ground of freedom from existential reference of even the most indirect, delayed, and ulterior kind. It is then mathematical' (LW 12, 393). However, symbols and mathematics are not fixed and final things in themselves, nor are they pure forms in some Platonic universe. They *are* abstract, and they do *not* generally participate in existential contexts; however, they have both their genesis and their purpose(s) in existential inquiries. Not only this, but they must operate to generate workable universal conceptions that can then order existential phenomenon, as Dewey says, 'The necessity of transformation of meanings in discourse in order to determine warranted existential propositions provides, nevertheless, the connecting link with the general pattern of inquiry' (LW 12, 393).

75.5.5 Scientific Inquiry and Social Science

Of central import to scientific inquiry is that it be of use in solving human problems. All inquiry takes place in social contexts, the contexts of human relations (LW 12, 481). What Dewey thinks is wrong with certain scientific research programmes is the failure to reinsert the results of scientific experimentation back into the existential conditions out of which all inquiry arises. Certain fields and programmes have become so esoteric as to have fractured the connection between findings and the existential situations out of which these findings emerged. (Logical positivism is one example of this.) This is to be deplored for Dewey; scientific research has an obligation to help aid in the solution to social problems, nowhere more so than with respect to the social sciences. Classes in particular are often treated as if they were universal conceptions, with the result that they are rendered fixed and final. In these situations, 'At best, inquiry is confined to determining whether or not objects have the traits that bring them under the scope of a given standardized conception—as still happens to a large extent in popular "judgments" in morals and politics' (LW 12, 264). Some of this state of affairs is due to the faulty methods which the social sciences pursue. Dewey admits the social sciences do not as yet possess the sophistication of methods and techniques common to the physical and natural sciences.

Dewey puts the matter this way: ‘The question is not whether the subject-matter of human relations is or can ever become a science in the sense in which physics is now a science, but whether it is such as to permit of the development of methods which, as far as they go, satisfy the logical conditions that have to be satisfied in other branches of inquiry’ (LW 12, 481). The existing methods of the social sciences have yet to allow for the logical conditions of the particular inquiries therein to be as rigorously developed and articulated as those in the physical and natural sciences.

However, it should not be concluded that the logical conditions themselves are different between the two kinds of inquiry. It is rather that it is much more difficult to convert the indeterminate situation in a social scientific inquiry into a determinate one than it is in a physical scientific inquiry, because of the complexity of social subject matters and the limitations of workable techniques and tools available to social scientists (LW 12, 485). Problems articulated in social scientific inquiry are ‘gross’ and ‘macroscopic’ in distinction to those in physical scientific inquiries (LW 12, 414). And though Dewey reminds that it is important to recognize and deal with ‘the physical conditions and laws of their interactions’, this is obviously not enough to go on for social scientific inquiry (LW 12, 486). New methods and techniques have to be developed to cope with the unique nature of social scientific subject matters. This cannot be a reductive social science, in which the techniques of the physical and natural sciences are transposed onto social scientific subject matters. ‘The assumption that social inquiry is scientific if proper techniques of observation and record (preferably statistical) are employed…fails to observe the logical conditions which in physical science give the techniques of observing and measuring their standing and force’ (LW 12, 492). Dewey continues, ‘Any problem of scientific inquiry that does not grow out of actual…social conditions is factitious; it is arbitrarily set by the inquirer instead of being objectively produced and controlled. All the techniques of observation employed in the advanced sciences may be conformed to, including the use of the best statistical methods to calculate probable errors…and yet the material ascertained be scientifically ‘dead’, i.e., irrelevant to a genuine issue, so that concern with it is hardly more than a form of intellectual busy work’ (LW 12, 492–493).

75.6 Inquiry and Science Education

In addition to Dewey’s claims for the importance of science and scientific inquiry in his philosophical and logical works, Dewey had a good deal to say about the role of scientific inquiry in education (see Chap. 42). As well, an increasing number of science educators have turned to Dewey to formulate better pedagogies and curricula for science education. Here, I will discuss Dewey’s claims for the role of scientific inquiry in science education; I will then turn to some of the more recent developments in science education conducted along Deweyan lines.

75.6.1 Science and Science Education

Science (and mathematics) education poses a unique and complex predicament for educators: the heightened and abstract nature of scientific findings (including the theories and laws of natural and physical science) are an impediment to learning. What makes scientific education a daunting task is not the lack of innate capabilities of children to master increasingly abstract conceptions, or various propositions; it is the haphazard way in which much science education is taught, together with the differences in background knowledge and techniques of students. A child's genuine inquiry cannot begin with such reified conclusions; rather, it must begin with simple observations and manipulation of the environment present-to-hand. 'What the pupil learns he at least understands. Moreover, by following, in connection with problems selected from the material of ordinary acquaintance, the methods by which scientific men have reached their perfected knowledge, he gains independent power to deal with material within his range, and avoids the mental confusion and intellectual distaste attendant upon studying matter whose meaning is only symbolic' (MW 9, 228). Rather than producing experts in scientific methods, the point of science education is to familiarize students with 'some insight into what scientific method means than that they should copy at long range and second hand the results which scientific men have reached' (MW 9, 229).

Dewey recommends what he calls the 'chronological method' in educating children to scientific inquiry. This is the method '…which begins with the experience of the learner and [that] develops from the proper modes of scientific treatment…' (MW 9, 228). Children are led up from simple observations and conclusions about the workings of their environment, through more sophisticated analyses and syntheses of isolated natural and physical phenomena. In these analyses and syntheses, children are encouraged to develop and apply the various forms of propositions and conceptions involved in actively ordering and controlling specific traits of phenomena under experimental circumstances. So, for example, what begins as a simple experiment to identify the conditions under which water evaporates in a puddle adjacent to the school (conditions such as a sunny day, increased temperature) becomes, as the student ages and is introduced to increasingly sophisticated techniques, an examination of the evaporation of water under strict laboratory conditions, with the use of such techniques as classes (liquids), universal conceptions (experimental hypotheses) and abstract conceptions (temperature, evaporation) and laws for liquids and gases, as well as tools for the examination of tendencies amongst large groups of phenomena, such as mathematics and statistics. Dewey surmises that if children were taught to use the 'chronological method' from the beginning of their formal education and consistently thereafter, much of the confusion that occurs in increasing the level of abstraction in science education would gradually diminish.

In order for students to engage experimentally with phenomena, they must actively engage the world around them. They must experiment with materials in various way and order and control traits of existential phenomena, beginning in a trial-and-error manner. This requires that the material to be tested have some connection to the child's life beyond the classroom. Otherwise, genuine problems—problems that are felt rather than deduced or prescribed—will not materialize. One of the best ways for this to occur is to begin scientific inquiry with available technologies and with existing social problems (MW 9, 232). Of technologies, Dewey says, 'The wonderful transformation of production and distribution known as the industrial revolution is the fruit of experimental science. Railways, steamboats, electric motors, telephone and telegraph, automobiles, aeroplanes and dirigibles are conspicuous evidences of the application of science in life. But none of them would be of much importance without the thousands of less sensational inventions by means of which natural science has been rendered tributary to our modern life' (MW 9, 232). Of social problems, Dewey has in mind the problems common to children at their particular developmental age and stage, as well as the particular problems of circumstance and context—including the barriers children face, such as those of race, class, gender and geography (MW 9, 91).

Properly conducted, inquiry in science education will begin with a 'felt difficulty'; an 'indeterminate situation' that then stimulates genuine interest. This is the crucial stage for inquiry in science education and, indeed, inquiry in all contexts. If genuine interest is not captured, any inquiry that results will be an externally motivated one certain to result in poor focus and haphazard conclusions. This problem is the child's, not the teacher's. It is a waste of time and energy for the teacher to simply pronounce on what problem the student will begin with, if the student hasn't come to see this problem on, and as, his or her own. Only with genuine interest can a problem be properly articulated so that it can satisfy the rigours of inference and testing that follow.

Once an articulated problem is produced, anticipatory consequences of acting on phenomena are put forth. This is an imaginative stage or phase of scientific inquiry, in which the student thinks through various possible courses of action. Upon deciding a course of action, the student will make use of tools of inference (as in formulating hypotheses of the 'If-then' sort, to test out specific anticipated outcomes; deduction, especially in terms of abstract concepts; induction and existential propositions of classes (all of this class or only some or none of this class). These are tools in the experimental phase of the inquiry that are put to work in order to achieve the desired outcome. Depending on the nature of the experiment and the tools and techniques available to the students, more or less attention will be spent on making this phase of the experiment and the tools of inference that belong to its self-conscious. Some of these tools and techniques can be taught and discussed; however, to be of value to the student in her experimentation, they must be developed and worked through *in* the experimentation.

Finally, if the experiment is successful, resolution or closure of the indeterminate situation takes place. Again, this is a felt, as opposed to abstract, resolution. Successful termination of scientific inquiry does not merely end in the 'right' result, or to the satisfaction of the teacher. On the objective side, it ends with the successful settlement of the indeterminate situation; on the subjective side, it ends when the student experiences a qualitative closure of the situation or event. Unless and until this qualitative closure or termination takes place, inquiry is not complete. And if inquiry is not complete, the impetus for further investigation that arises as a result of the satisfaction of having closure of an indeterminate situation is denied. Closure is the ‘aha’ moment when an experience is at its most satisfying. And this is the moment of genuine growth. To deny or otherwise not conclude with this moment is to blunt the motive force for future scientific inquiries.

However, Dewey recognizes that these changes to the structure and content of science education are not, by themselves, enough; differences in background knowledge are another matter entirely. These cannot be so easily remedied and require changes in existing social and political realities—realities that have resulted in the barriers of race, class and gender and lack of education that keep some disenfranchised (MW 9, 91). Unfortunately, individual schools are hampered in their ability to mitigate circumstances such as poverty, racial and gender bigotry and socioeconomic divides. Inquiry, though inestimably important to students’ intellectual development and their capacity to solve problems, needs to be heavily supplemented with cooperative social institutions and programmes if it is going to overcome the paucity of genuine intellectual growth that results from social barriers and divides.

75.6.2 Deweyan Inquiry and Constructivism in Science Education

Dewey has been a central figure in the great mass of scholarship written on behalf of constructivism in science and science education (Von Glaserfeld 1984, 1998; Phillips 1995; Garrison 1995, 1997a; Vanderstraeten 2002; Kruckeberg 2006; Gordon 2009). While some are content to note Dewey’s historical influence on later philosophers (such as Richard Rorty) is squarely in line with constructivist beliefs and others are content to point out that Dewey’s anti-metaphysical insistence in matters of knowledge is of a piece with their constructivist values, still others have gone further and developed Deweyan accounts of constructivism. Here, I will examine briefly constructivism in science education, noting how and where Dewey is invoked. I will then turn to a very brief exposition of three accounts of Dewey in the name of constructivism and science education: Ernst Von Glasersfeld’s ‘radical constructivism’, Jim Garrison’s ‘social pragmatic constructivism’ and Raf Vanderstraeten’s ‘transactional constructivism’.

It will do to outline briefly the thinking behind the constructivist movement in education. Constructivism is a label for a variety of various, like-minded models of cognition and knowledge that share a history, as well as a central tenet: the rejection of metaphysical realist and empiricist theories of knowledge, often in favour of developmental and transactional accounts that stress the organism of person’s own role in knowledge acquisition (LaRochelle and Bednarz 1998, p. 7). In education there are ‘radical constructivisms’, ‘pragmatic social constructivisms’, ‘didactic constructivisms’ and ‘poststructuralist constructivisms’, amongst others. Dewey’s involvement in constructivism comes largely as a result of his own rejection of metaphysical accounts of knowledge creation and production. Inquiry in constructivist accounts of science education invoking Dewey generally stresses the anti-metaphysical and anti-dualist dimensions of his thinking in their respective projects for science education. However, some thinkers have been compelled to go further and investigate the particular areas where Dewey's account of knowledge creation and production reaches beyond complementarity with existing understandings of constructivism in science education to form a distinctive constructivism in its own right.

Both Garrison and Ernst Von Glasersfeld draw on Dewey in their respective understandings of constructivism, and it will do to discuss their differences. Von Glasersfeld considers himself a 'radical' constructivist, a position Von Glasersfeld says he owes to Kant, Piaget and the notion of 'variability'—the idea that all conceptual schemes are premised on their utility or purpose (Von Glaserfeld 1984, p. 12). Von Glasersfeld appropriates certain of Kant's understandings to elaborate his own articulations of conceptual schemes. For example, Von Glasersfeld appropriates Kant through saying his understanding of reciprocity (as discussed by Kant as the Third Analogy of Experience) is beneficial to understanding how shared conceptual schemes develop. In the Third Analogy, 'All substances, insofar as they can be perceived in space as simultaneous, are in thoroughgoing interaction' (Kant 1998, p. A 211). This has obvious utility to Newton's third law of motion. And it has utility as well to Von Glasersfeld, who quotes Kant approvingly; 'It is manifest that, if one wants to imagine a thinking being, one would have to put oneself in its place and to impute one's own subject to the object one intended to consider…' (Von Glaserfeld 1998, p. 124). This 'reciprocity', analogized further from Kant's Third Analogy, is said by Von Glasersfeld to be akin to how we develop our shared, conceptual schemes. Von Glasersfeld does not intend to claim Kant's understanding and use of reciprocity as completely his own; he is rather content to accept the analogy and turn to empirical factors such as adaptation to understand constructivism. His is a "cognitive constructivism," which also has its locus in the seminal works of Piaget. Yet, this 'cognitive constructivism', as a theory invoking the transcendental substrates of Kant, sharply distinguishes Von Glasersfeld's project from empirically inclined projects such as Garrison's (Grandy 1998, p. 115).

Garrison's account of Dewey's 'pragmatic social constructivism' presents Dewey as a social behaviourist who is inimical to mental representations (Garrison 1995, p. 717). While Garrison clearly endorses a Dewey that evinces a strong role for natural (non-mentalistic) conceptions, his endorsement does not extend to wholly subjective or mentalistic representations, which he sees operating in Von Glasersfeld's account of 'radical constructivism'. Garrison's Dewey stresses language as a social construction, together with 'dialogicality and multiple authorship' (Garrison 1995, p. 727). Unlike Von Glasersfeld's understanding of constructivism, Dewey's account is anti-dualist and anti-subjectivist (Garrison 1997a, p. 305). Indeed, Dewey's theories of mind and meaning were *entirely* behaviourist (Garrison 1995, p. 725; 1997a, p. 308), and mind for Dewey was entirely a social construction. Social behaviour—the behaviour existing between and within social units—transforms organic behaviour as a result of (shared) language into meaningful behaviour (Garrison 1997a, p. 308). Garrison claims that rather than focusing on traditional epistemic tasks, education and science education in particular should be attempting to construct stronger models of dialogicality and promote active listening.

Vanderstraeten's account of Dewey's 'transactional constructivism' begins with an analysis of Dewey's organic account of coordination and perception (Vanderstraeten 2002, p. 236). This leads to an analysis of habit, to thinking and to knowledge formulation and the ways these form an integral whole. Communication (as with Garrison) is key in all of this. Education is a means of communication and education is 'a participatory, co-constructive process' (Vanderstraeten 2002, p. 241). Objects and practices acquire shared meaning because they are part of larger and shared sets of experiences (Vanderstraeten 2002, p. 241). Knowing is an active construction that takes place in the organism-environment transaction. This Vanderstraeten contrasts to Von Glasersfeld's 'radical constructivism', which he seems to see as insufficiently 'deep' to thwart the accusations that it is one more example of an account of correspondence to reality (Vanderstraeten 2002, p. 243). Garrison and Vanderstraeten thus both share an antipathy towards mentalistic representations and a regard for a 'transactional' accounting of constructivism in education.

It is difficult to evaluate the various constructivisms developed in Dewey's name. They clearly concentrate on central themes and concerns of Dewey and to do so is correct. The focus on transaction of the child and environment and the social dimension(s) of experience are vitally important to any further pedagogy of science, as is the stress on communication and dialogue. Beyond this, it is unclear how helpful it is to include Dewey in the pantheon of constructivists, let alone develop a constructivism from his various educational and philosophical writings. While Dewey shares many of the intellectual proclivities of other constructivists (including constructivist science educators), it remains to be seen what tangible benefits to science education come from including Dewey in this pantheon. Much if not most of the work in constructivism is content to present accounts of Dewey that do little to advance our understanding of him beyond what has elsewhere been articulated.

I attribute much of this lack of advance to the superficial nature of the readings of Dewey. In my opinion, seldom do constructivists dig deep enough to reveal the connections between Dewey's theories of knowledge and logic and his theory of aesthetic experience, to say nothing of his social and political writings (Garrison is the exception, here). More problematically, running Dewey together with Kant and Piaget as Von Glasersfeld does serves to mask tremendous underlying differences in their respective epistemologies: if Kant, as a transcendentalist, was a constructivist and Dewey, as a naturalistic empiricist, was a constructivist, it becomes a huge task to explain what foundation constructivism rests upon. Sadly, most constructivists (Garrison is again the exception) do not probe the foundations, and the resultant constructivisms they champion are but castles made of sand (see Chap. 31).

75.6.3 Dewey and the Science Curriculum

Dewey's written output while serving as the head of the University of Chicago Laboratory School (1896–1903) is well known to most educators. It includes *School and Society* (1899) as well as numerous monographs on various aspects of pedagogy and curriculum. Additionally, historical, biographical and philosophical work on the Laboratory School (Camp Mayhew and Camp Edwards 1936; Wirth 1979; Tanner 1997; Johnston 2006) has invoked inquiry directly. Recently, curriculum leaders and scholars have developed novel understandings of science education with a strong role, if not a focus, for inquiry to play. I will discuss some of these further.

Inquiry has become a dominant theme in science education (Rudolph 2005, p. 43). Aside from its logical features, this generally extends to 'hands-on' manipulation of objects, the emphasis on 'real world' activities and the use of associated technologies. As well, projects, where a number of related exercises are undertaken as part of a larger curricular whole, are often stressed. The continuity between a child's past experiences and those the teacher wishes the child to undergo is also maintained (Howes 2008, p. 538). Models of science education for early childhood education that propose drawing on a child's basic impulses to create further situations for the development of intelligent dispositions and skills have also been developed (Howes 2008, p. 538). Beyond this, more specific accounts of Dewey's holism and particularly how science and science education merges with art and aesthetic experience in an organic accounting have been offered. These latter accounts have been developed simultaneously by philosophers of education (Garrison 1997) and curriculum scholars such as those working at the Dewey Ideas Group at Michigan State (Wong and Pugh 2001; Girod and Wong 2002; Pugh and Girod 2007). All stress the importance of inquiry in regards to science education.

Garrison stresses the importance of aesthetic experience and particularly the precognitive background we draw upon when we inquire (1997b, p. 101–102). The logics that we use when we solve educational problems rely on this precognitive background and inform them. Garrison's point is to underscore the situation-specific nature of logic; there is no one logical method right for all situations; the situation itself will very often dictate what logical processes are to operate (Garrison 1997b, p. 98). Attention to the background conditions of experience, as well as the particular experience a child forms, is thus vital for science educators if they are to gauge successfully the student's learning.

Wong, Girod and Pugh also stress the precognitive dimension of experience. This drives instrumental understanding and forms the context out of which instrumental understanding operates (Girod and Wong 2002, p. 200). Like Garrison, these scholars concentrate on the motivation for learning in the first place, rather than the specific logical steps or processes undertaken. This necessitates concentrating on the experiences students have, rather than the outcomes of the particular lesson. A focus on the relationship between the concepts and ideas developed in the lesson and the experience the student has, together with attention to the satisfaction and interest inherent in genuine experiencing, is key (Pugh and Girod 2007, p. 14–16). Aesthetic experience is at once the highest and deepest of the forms of experience had and undergone. Helping to bring a child to have an aesthetic experience involving scientific experimentation is to ensure that genuine learning is taking place. Doing so releases the 'transforming' and 'unifying' elements of aesthetic understanding (Girod and Wong 2002, p. 208). The satisfaction had in having and undergoing the aesthetic experience of a scientific experiment through all of its phases is the basis for the development of real, as opposed to merely rote, knowing. Thus, in crafting science lessons, aesthetic experience must be borne in mind. This is not to say that other forms of experience are valueless; however, facilitating an aesthetic experience is the surest means to the 'teachable moment' that teachers value above all.

75.6.4 Dewey and the Teaching of Science

Problem-solving, discovery and inquiry methods are popular and well represented in theories of teaching science, in part due to Dewey's role in connecting his theory of inquiry to educational situations and events (Glassman 2001). All of these methods insist on taking the needs, desires, attitudes and developmental ages and stages of students as primary in the facilitation of science education, rather than teaching the discipline as a coherent subject matter (Eshach 1997). Concentrating on students' experiences rather than on the dissemination of the subject matter, together with a focus on the active role played by students in investigating natural phenomena, is paramount. This insists the teacher manipulate the environment to help facilitate the students' experiences such that they can actively inquire, in the manner of the stages of inquiry Dewey discusses in *How We Think* and elsewhere.

This facilitation of experiences also insists on conducting science in a manner similar to how scientists conduct it themselves, in their experimental investigations. Science, as Dewey insists, does not occur in isolation: nor should science education. The scientific investigation of natural phenomena is most clearly reproduced when students work in teams or groups, conducting an inquiry from beginning to end (from the first to the final stage of inquiry), rather than learning isolated facts or formulae from a textbook. Models of cooperative learning often cite Dewey as an early exponent (e.g. Brown and Palincsar 1989, p. 397–398). Furthermore, scientific investigation demands corroboration of results and not simply the findings of an isolated experiment (Eshach 1997). Writing up results and (re)testing them are as vital to science as the initial experimentation, and both must be included in a programme of science education. This might include both whole-class discussion and the writing of novel 'texts', particularly in the elementary grades (Howes 2008, p. 545).

Recently, it has been suggested that Dewey's understanding of scientific inquiry and science education be utilized to help integrate existing rival theories such as constructivism and objectivism under the rubric of scientific literacy (Willison and Taylor 2009, p. 32). It is argued that this may help resolve some of the tension that keeps at bay the practical advices nesting in the various theories. Dewey has also been invoked in the ongoing debates about the role of science education in the overall preparation of students: while the standards-based push to increase scientific subject matter and instructional time in public schools is laudable, it is also the case that what gets pushed first is very often abstract concepts, formulae and principles at the expense of context and experimentation (Rudolph 2005, p. 806; Chinn and Malhotra 2002, p. 199). Dewey's understanding of the contexts of scientific inquiry is a valuable corrective in this regard.

75.6.5 Overall Assessment of Dewey's Role in Science Education

Deweyan models of science education have been helpful, particularly in stressing the cooperative nature of learning, the experimental nature of knowledge acquisition and the aesthetic dimensions of children's' experiences. It makes good theoretical sense to concentrate our attention on issues of interest, motivation, satisfaction and other 'traits' of experience that bookend inquiry in science education. Furthermore, invoking Dewey, scholars and practitioners have developed comprehensive models of science education that do not resemble cookbooks or 'how-to' manuals (or lists of objectives and standards). As well, they have contextualized intellectual tools such as concepts, ideas, algorithms and processes. Rather than being set off from the curriculum or subject matter, inquiry is now thoroughly integrated in these models. And rather than being a procedure that is separate from the child or a set of steps or stages the child must plod her way through, inquiry is now seen as a process involving her experience throughout.

However, much of the scholarship on Dewey in science education has been content to draw on Dewey in so superficial a fashion that little of Dewey's actual logical, epistemological or experiential philosophy has been adequately mined. What remains for science educators using Dewey's philosophy of education is to further connect Dewey's theories of experience and art with his theory of logic—especially the accounts of propositions and conceptions he details in *Logic: the Theory of Inquiry*. A suitably comprehensive account of Deweyan inquiry for science education (one that integrates both experience and the tools of logical inquiry) has yet to be fashioned. Beyond this, educators must do a better overall job of convincing sceptics (and there are many) that think Deweyan-inspired methods of science education will reap advantageous results. To give but one example, criticisms regarding the bracketing or ignoring of psychological research that indicates the importance of working memory have been raised against constructivism and inquiry-based teaching:

> Any instructional theory that ignores the limits of working memory when dealing with novel information or ignores the disappearance of those limits when dealing with familiar information is unlikely to be effective. Recommendations advocating minimal guidance during instruction proceed as though working memory does not exist or, if it does exist, that it has no relevant limitations when dealing with novel information, the very information of interest to constructivist teaching procedures. We know that problem solving, which is

> central to one instructional procedure advocating minimal guidance, called inquiry-based instruction, places a huge burden on working memory….The onus should surely be on those who support inquiry-based instruction to explain how such a procedure circumvents the well-known limits of working memory when dealing with novel information. (Kirschner et al. 2006, p. 77)

These concerns are to be taken seriously. As these are empirical concerns, they must be addressed empirically. To address these means not simply providing a re-articulation of Dewey's texts (though this is valuable initially); rather, further articulation of Dewey's understanding, further articulation of the application of Dewey's understanding of science and science education to various teaching practices and further empirical verification of this reconstructed articulation through experimental design must be demonstrated. In other words, the way to address these concerns is through following the stages of inquiry from articulation of the problem to hypothesis testing and the formation of anticipated consequences (the formation of universal conceptions), to rigorous testing (using the 'tools' of induction and deduction, as well as the construction and invocation of abstract concepts) and to evaluation in the empirical setting in which the problem is first felt and articulated. Following the lines of Dewey's theory of inquiry is the only reasonable way to reveal problems with the empirical investigations undertaken in the quest to confirm or disconfirm claims on behalf of inquiry, discovery or problem-solving methods.

75.7 Conclusion: Dewey and Science Education

Dewey has and doubtless will continue to provide fertile ground for explorations into various dimensions of scientific inquiry and science education, including pedagogy and the curriculum. Dewey's account of inquiry offers advantages other accounts very often lack: it is holistic, context-bound and self-correcting; it is rooted in experience and the generic 'traits of existence' that arise out of the transactions of human beings and their environments (including the 'social' environment of other people). Yet, it is rigorous in its logical processes, with a strong and detailed accounting of conceptions, ideas, proposition and other logical functions. Historically, it has been vitally important for various accounts of pedagogy and curriculum.

The state of Deweyan scholarship on science education is another matter; as it stands, Dewey scholarship in science education repeats many of same mantras as Dewey scholarship in other areas of education: the importance of inquiry, discovery and problem-based methods and pedagogies; group, cooperative and team-oriented projects; and an emphasis of experimental learning over and against disciplinary or subject matter learning (at least for the elementary grades). However, it has not progressed much beyond these, despite the invocation of Dewey in constructivism and other fashionable models of teaching and curriculum. In my opinion, what is necessary for further scholarship is to develop a cogent model of Deweyan inquiry for science education that integrates Dewey's accounts of experience and art with his detailed account of the functions of logical inquiry, including the tools of conception, propositions and symbols. Doing so requires us to dig deeper into Dewey's logical, epistemological and experiential theories than is usually done. A few scholars (e.g. Garrison) have begun this scholarship, but much more work on the part of the Deweyan community of scholars remains. A systematic model of science education that is attentive to logical, epistemological, experiential and social-political as well as educational concerns will be of inestimable value for further pedagogical and curricular claims on behalf of science education. Beyond this, it remains to be seen whether any of these accounts of science education invoking the name or scholarship of Dewey are able to penetrate the morass of objectives-driven 'standard' science education.

Chapter 76
Joseph J. Schwab: His Work and His Legacy

George E. DeBoer

76.1 Introduction

Most science educators are familiar with Joseph Schwab because of his contributions to the school reform movement in biology in the United States in the 1960s, especially through his connection to the Biological Sciences Curriculum Study (BSCS) (see, e.g., DeBoer 1991). Schwab brought terms like "rhetoric of conclusions" and "narrative of enquiry"[1] to the discussion of school science, and he contributed to the reform of science education as chair of the Teacher Preparation Committee at BSCS and as author of the *Biology Teachers Handbook* (Schwab 1963a). But most of Schwab's work in science education was not focused on the school curriculum, rather on the undergraduate science program while he was on the faculty at the University of Chicago. His ideas about the nature of the science curriculum were shaped as he and his colleagues at Chicago worked out the details of a comprehensive program of general education[2] for the undergraduate college. It was at Chicago that his professional career began and where it ended 36 years later, and it was at Chicago that he thought and wrote about science education, first for undergraduate students and then later as part of the precollege science curriculum reforms of the 1950s and 1960s.

Joseph Schwab was born in Columbus, Mississippi, in 1909; matriculated as an undergraduate at age 15 at the University of Chicago in 1924; and graduated with degrees in physics and biology in 1930. He earned a doctorate in genetics from

---

[1] Schwab preferred "enquiry" to "inquiry," but in his writing the spelling varies depending on where the work was published. In this chapter, the spelling that actually appeared in a publication will be used, and all my discussions of his work will use the word inquiry.

[2] The terms *general education* and *liberal education* will be used synonymously in this chapter to describe nonspecialized and nonvocational programs of study that offer students a broad base of experience with various modes of thought and knowledge of their culture.

M.R. Matthews (ed.), *International Handbook of Research in History, Philosophy and Science Teaching*, DOI 10.1007/978-94-007-7654-8_76,

Chicago in 1939. In 1937, he spent a year at Columbia University Teachers College, where he was influenced by both John Dewey and Ralph Tyler. Schwab came to Chicago as an instructor in 1938, and he retired as professor of education and the William Rainey Harper professor of natural sciences in 1974. He then joined the Center for the Study of Democratic Institutions, founded by Robert Maynard Hutchins, in Santa Barbara, California, where he continued to think and write about curriculum. He died in Lancaster, Pennsylvania, in 1988.

He began his graduate work at Chicago just as Hutchins was beginning his long tenure, first as president (1929–1945) and then as chancellor of the university (1945–1951). This was also the time that the college was beginning to embark on its decadelong experiment in general education. Hutchins was a vigorous advocate of the Great Books approach to general education and a promoter of liberal education as the best preparation for informed, responsible citizenship (Hutchins 1936). Hutchins believed that undergraduate education should focus on a student's intellectual development through a careful study of classic works of Western civilization, taught through a dialectical Socratic method, rather than on the development of practical skills and professional training, which tended to characterize higher education at that time. His approach was intended to develop citizens with the independence of mind suited for life in a democratic society. The study of a core body of great works would also provide a common educational experience so that citizens could communicate beyond their areas of specialized interest.

Hutchins was joined in 1930 by Mortimer Adler and, with Adler, went on to found the Great Books of the Western World program and the Great Books Foundation in 1947 (http://www.greatbooks.org/about/history). But the faculty rejected Hutchins' plan for a Great Books approach for the undergraduate college, and the program never became the model of undergraduate education at Chicago that it did at St. John's College in Annapolis, Maryland. However, its focus on the intellectual heritage of Western civilization did influence the spirit and forms the general education program took at Chicago, and the approach was used in the university's adult evening extension college, which Schwab chaired when he joined the faculty in 1938.

Although Schwab's primary interest and responsibility was organizing the science curriculum for the general education program at Chicago, the integrative nature of general education also gave him opportunities to think about the role of the social sciences and humanities in general education and the boundaries between those subject areas and the sciences. He had a passion for psychology, social sciences, religion, and humanities, and he addressed issues from these disciplines in his writing on education. In addition to being a member of the science faculty, Schwab was also a respected education theorist. In 1949 he was appointed to the university's education department, where he taught courses in the philosophy of education. And later he did curriculum work at the Melton Research Center of the Jewish Theological Seminary, where he helped develop materials to teach character education to students attending Jewish summer camps.

He had an especially strong interest in psychoanalysis, undergoing analysis himself. In *Eros and Education* (1954) Schwab wrote about the nature of the interactions between faculty and students during classroom discussions from a Freudian perspective. In the late 1950s and early 1960s, his attention shifted to the school science curriculum reform movement through his work with BSCS. In 1969, his attention shifted back to higher education as the student protest movement gained momentum. In response to the protests, he published the *College Curriculum and Student Protest* (Schwab 1969a), in which he focused again on the role of liberal education in society, especially on ideas of "community, of moral choice, and of deliberation and decision-making" (Westbury and Wilkof 1978, p. 30). His final contributions to the field of education were to curriculum development in general. Through a series of papers on the advantages of a practical rather than theoretical approach to curriculum study, he became well known among curriculum theorists for his claim that "the field of curriculum is moribund" (Schwab 1970, p. 1).

76.2 The Undergraduate College at Chicago

Throughout the 1930s, a group of University of Chicago faculty pressed forward on a plan to create a coherent and well-integrated approach to general education for the undergraduate college. In 1937, a four-year program of undergraduate study, completely devoted to general education, was officially approved by the university (Schwab 1950a). When Schwab joined the faculty in 1938, he took a leading role in the development of the science component of the program as chair of the natural sciences sequence in the undergraduate college, and it was his efforts to conceptualize that program to which he devoted most of his professional career.

The early to mid-twentieth century was a time of vigorous debate about the role of undergraduate education at colleges and universities in the United States. At its beginning, higher education in the United States had had a classical character, with a focus on classical literature and languages. But by the mid to late nineteenth century, the model of the German university, with its emphasis on specialization and empirical investigations in the sciences, began to take hold in the United States and elsewhere. By the late nineteenth century, that model began to predominate in universities like Chicago. As Daniel Bell put it:

> The American university, as it emerged in the latter decades of the nineteenth century, brought with it a new religion of research. Even scholarship in the traditional disciplines was conceived, within that purview, as being concerned with detailed and specialized problems. The reaction of the liberal arts college was to strike out against specialism. (Bell 1966, p. 51)

Questions began to be raised in universities across the United States about the appropriate role of the undergraduate experience, coming as it does between the high school and the professional and graduate schools: Should the undergraduate years be spent in preprofessional training for those planning to enter the professional schools, should it focus on early scholarly preparation for those going on to graduate school, or should it simply be preparation for informed citizenry? What, if any, is the importance of having students develop an appreciation for the cultural artifacts that the society thinks a cultivated person should be familiar with, to become aware of basic principles that guide moral behavior, or to gain an understanding of how knowledge is organized and revised? And how important is it for citizens in a democratic society to have a shared intellectual experience that provides them with a common ground for deliberation and debate regardless of their life work or specialization? These were the questions that were being debated.

The programs of general education being developed at Chicago, along with those at places like Columbia and Harvard, became models for colleges throughout the country. (See Bell (1966) for a discussion of the Chicago, Columbia, and Harvard experiments in general education.) Although these programs differed in detail, they all had a commitment to certain general principles and purposes. As Bell said in his study of general education, the function of a general education program in the undergraduate college was:

> …to teach modes of conceptualization, explanation, and verification of knowledge. As between the secondary school, with its emphasis on primary skills and factual data, and the graduate or professional school, whose necessary concern is with specialization and technique, the distinctive function of the college is to deal with the grounds of knowledge: not *what* one knows but *how* one knows. The college can be the unique place where students acquire self-consciousness, historical consciousness, and methodological consciousness. (Bell 1966, p. 8)

General education programs such as this had as their stated purpose the development of enlightened and responsible citizens for life in a free society. They emphasized personal growth and individuality and a universal rather than a provincial or nationalistic world view. Programs usually focused on the humanities and classics, particularly the study of Western civilization, and they avoided connections with utilitarian and vocational aims and with career preparation. But programs were not all the same. They differed in the emphasis they placed on developing moral men and women versus providing students with a broad understanding of multiple ethical perspectives, the importance they placed on learning about the heritage of the society versus studying the contemporary world, and how much they valued the acquisition of a broad base of knowledge across the curriculum compared to providing students opportunities to develop skills as independent thinkers.[3]

For example, the stated purpose of the Chicago program was to develop the intellect. It was not primarily about the knowledge one acquired, but rather the ability to think, to contemplate, and to consider alternatives. To do that well, one had to learn about the complexities of the world in relation to each other. The most important job of the college was to introduce students to positions other than their own and to help them develop the power to form judgments. In the Chicago program, that thinking would take place in the context of cultural elements (works of art, music, literature, and science) that were deemed to be most important by society. The task of curriculum developers was to create curricular content and learning activities that allowed students to investigate these cultural elements thoroughly and in context. The Chicago program also took an analytical approach to knowledge rather than the

historical approach that often characterized general education programs. Especially in the sciences, and largely through Schwab's influence, the goal of the curriculum developers was, in Bell's words, "to find the controlling principles of 'classification' in the definition of subjects or of disciplines within fields" (Bell 1966, p. 33). Referring to the difference between these two approaches in the context of science, Bell said:

> …the question is whether one wants to emphasize historicism, with its doctrine that the understanding of an event can be found only in its unique context, or the analytical approach, which finds meaning in a phenomenon as one of a type-class, and seeks, further, a sense of invariant relationships. …Does one teach science through its history, or by analysis of its models of inquiry? (p. 62)

At Chicago, general education meant learning the special modes of conceptualization that characterized each discipline, not simply reviewing the historical development of a field. Historical texts were read and examined, but the purpose was not just to familiarize students with the knowledge these texts contained but to teach students how different forms of knowledge were created and how the students themselves could be analytical and critical of those intellectual methods and products.

At Chicago, this was to be accomplished by means of an interpretive (hermeneutic) approach in which students extracted meaning from selected written texts, pieces of music, works of art and architecture, and reports of scientific investigations, taking into consideration not only the cultural artifacts themselves but also the purposes and intentions of the creator of those artifacts. Nothing was to be taken as given, but always open to analysis and interpretation. In science, the texts that were subjected to interpretation were original scientific research papers, and the pedagogical approach for teaching them involved having students examine those papers to become familiar with the particular knowledge claims that were made, the investigative methods used, and the broader intellectual and practical contexts in which each investigation was conducted (Schwab 1950a).

The challenge that Schwab and his colleagues faced was how to create an educational experience that would lead to intellectual growth so that students would be open-minded, skeptical, able to think for themselves, and prepared to take on positions of leadership in society. The education that was envisioned emphasized the integration of knowledge from multiple disciplines and a search for and an appreciation of fundamental principles that define human experience, accomplished not through memorization but through discussion and deliberation.

But, even as efforts were under way in places like Chicago to build general education programs, the overall trend in undergraduate education was toward specialization, professional and preprofessional training, and the accumulation of knowledge. As Schwab noted, a "rhetoric of conclusions" dominated undergraduate teaching, where students were presented with knowledge of the disciplines without being required to think critically or make judgments about that knowledge. Many of these issues were addressed in the scholarly writing that Schwab was engaged in while he was the chair of the science program in the undergraduate college at Chicago, and it is to that work that we turn in the next several sections of this chapter.

76.3 The Place of Science in Liberal Education

76.3.1 A Taxonomy of Types of Science

In 1949, Schwab published a paper titled *The Nature of Scientific Knowledge as Related to Liberal Education*. In that paper he argued that all students should be exposed to the breadth and variety of science both in its content and its methods. Science should not be treated monolithically but as a complex and varied study. To accurately represent the complex nature of the physical world and the methods used to study it, liberal education should use pedagogical approaches that reflect that complexity. Diversity exists in the content and methodologies of the separate fields of science, and diversity exists in how philosophers of science view the nature of science, including the nature of causality, the nature of induction, the role of hypothesis testing, and the relationship between mathematical knowledge and the physical world. Schwab argued that because of this diversity of methods that are used and views that are held about the nature of science, no one single set of "epistemic or metaphysical presuppositions" concerning science can cover the variety of ideas that exists (Schwab 1949, p. 248). An accurate portrayal of the nature of science as part of a liberal arts education requires that this diversity of scientific methodology and interpretation be taught as fully as possible.

Schwab proposed a taxonomy of scientific investigation that could serve as an aid to the teaching of science in a general education program, both to support the choice of subject matter and how that subject matter could be examined by students. He identified four types of scientific investigations, which differ from each other in the kind of knowledge that is generated, the kind of data that are collected, and the form of validation that is used in each. The four types, which he believed encompassed most forms of scientific inquiry, were taxonomic science, measurement science, causal science, and relational or analogical science.

Taxonomic science involves the creation of classification schemes for organizing objects and events in the world. These classification schemes exist in virtually all fields of science, including the classification of disease for diagnostic purposes, categorizing living organisms to study their degree of hereditary relatedness, or the classification of types of chemical molecules on the basis of their molecular structures. All of these classification schemes were developed for a purpose, and all of them require difficult decisions at the margins. For the purpose of liberal study, "…a given taxonomic system is understood when it is seen as one of several alternatives" and when "…some of the doubtful areas of the taxonomy are seen and some of the reasons for their doubtful status understood" (Schwab 1949, pp. 255–256).

Measurement science involves measuring and relating changes in two or more objective quantities. Familiar examples include the relationship between the intensity of light and distance from the light source, the frequency of vibration of a plucked string and the length of the string, or the degree of sinking of an object and its density in relation to the density of the medium it is immersed in. For general education purposes, it is important that students understand that assumptions are made when reporting these relationships in a mathematical form, such as the assumption that there is a point source of light (which is an idealization of the real world). Students should also be aware of the possible effects of abstracting only certain variables of interest from a more complex set of related variables that could be studied.

Regarding *causal science*, Schwab argues that much of what is thought of as "causal science" can actually be placed in the other three categories, but even after doing that, there remains a separate type of investigation that deals with systems of mutually interacting and mutually determined parts acting as a whole. He cites physiological and social systems as examples. The defining features of these causal systems involve "interaction, mutual determination, and concerted action" (Schwab 1949, pp. 258). The challenge for students is to grasp the nature of the interacting parts of the system and their relationship to the whole organism or system. Of necessity, because these systems are too complex to be studied as a unity, their parts and pieces must be studied in isolation. For general education purposes, the student:

> …must be prepared to discover, in the records of such research, answers to the questions of what kinds of "parts" are being treated, what analysis of "functions" are related to the parts and functions of other related researches, and how, if at all, the researcher in question relates his discovered functions and parts to one another to constitute larger units more nearly approaching the unity of the organism as a whole. (Schwab 1949, p. 260)

Finally, Schwab identified *relational science* as a fourth type of scientific inquiry. Regarding this type of inquiry, which relies on models, analogies, and forms of representation, Schwab said:

> By "relational science" I mean those patterns of inquiry which are most fully understood as aiming toward knowledge which attempts to "explain" or "account for" matters previously known by inventing co-related quantities which do not have one-to-one correlates among the phenomena to be accounted for, or by inventing mechanisms not directly accessible to observation but so conceived and applied to the phenomena to be explained that it can be said that certain things behave *as if* these mechanisms existed. (Schwab 1949, p. 260)

These borrowed relationships of relational science, which are applied to the new observations, may come from either physical models or from abstract mathematical and conceptual models.

The educational imperative of these diverse approaches to scientific investigation is that students should have enough familiarity with them to analyze actual research studies in each category and make comparisons between them. Instruction should "…educate, encourage, and exercise the student in applying appropriate canons of comprehension and evaluation to…examples of scientific inquiry" (Schwab 1949, p. 264). This enables students to make judgments about which of a number of possible alternatives is the most appropriate approach to collecting data, drawing conclusions, and linking evidence to conclusions, which in turn will give students a more honest and accurate picture of the physical world and how it is studied. When the nature of science itself is chosen as the subject for students to study, then a variety of historical, philosophical, and methodological interpretations of science should be read, discussed, and analyzed in the same way.

76.3.2 The Tentative Nature of Science

Also key to an understanding of science for liberal education purposes was to appreciate “the ongoing, unclosed character of science” (Schwab 1949, p. 263). Yet, as Schwab observed, colleges still taught “the conclusions of science and definitive solutions to its problems” (p. 263). Teaching the tentativeness of conclusions did not, however, argue for naïve relativism to Schwab. It meant simply that in order to be honest about the nature of science, differences in how the world is viewed by individuals studying the same problem needed to be treated thoroughly. Instruction must teach students “the disciplines of comparison, contrast, choice, and synthesis appropriate to the field in which the diversity takes place” (p. 264).

The pedagogical challenge of such an intellectually sophisticated approach to teaching science was how to get students familiar with and to contemplate the relevance of each these diverse modes of scientific inquiry in the limited time allotted. To Schwab (and his colleagues at Chicago), the answer lay in the analysis of carefully chosen scientific research papers. A scientific research paper is the “bearer of a portion of scientific knowledge in its field,” and “…it ‘illustrates itself’ as an example of scientific investigation” (Schwab 1949, p. 265). All that is required is that the student knows what questions to ask, including what problem is being addressed, the appropriateness of the data, difficulties in obtaining data, how the data were treated, any phenomena that were excluded, and the validity of the conclusions. Each paper “would serve simultaneously to impart subject-matter content and to illustrate aspects of the nature of scientific knowledge at many different levels—from the most specific level at which the paper falls…to the level of science-as-a-whole” (Schwab 1949, p. 251). In the plan developed at Chicago, students would be presented with sets of such papers and with a framework for analyzing them so that they would gain practice in studying those investigations as instances of scientific inquiry, especially how each was similar to and differed from the others.

76.3.3 Science as Constructed Theory

In *Science and Civil Discourse* (Schwab 1956), Schwab elaborates further on the nature of inquiry in science and its importance in liberal education. He says that inquiry is constructive in the sense that conceptions “must be invented…by the investigator” in order to determine what his subject matter and his data will be from the great “complex of things and events” (Schwab 1956, p. 132). According to Schwab, through this process of problem and data selection, the content is inevitably “distorted” and “made incomplete.” Therefore, because of this selecting and narrowing of the problem and consequent narrowing of what is observed, a conclusion in science must be thought of as a “taken something, not an objectively given something” (Schwab 1956, p. 132).

This constructive character of scientific knowledge has implications for the liberal arts curriculum. Schwab argued that if a theory is to be taught as a theory about some aspect of the world, it is also important to be clear about which aspects of the subject are not incorporated into that theory:

> We must have something more in the materials of our curriculum than the theories themselves, for the restrictions which define what the theory is about are not readily found in the theory itself. The theory is only the terminal part of an inquiry. We need what comes before the end…to discover what the theory is a theory of…. (Schwab 1956, p. 133)

This means that the student needs to know that scientific problems are constructed out of a much larger array of possibilities, and they should come to appreciate the choices that are made by scientists in the selection of problems, the selection of observations to be made and data to be collected, and how the data are interpreted in terms of existing theory.

76.3.4 Structure of the Disciplines

Although much of Schwab's work involved efforts to integrate scientific knowledge throughout the liberal arts curriculum by showing the interconnections between subject matters across disciplinary boundaries, he also acknowledged the importance of the separate academic disciplines for curriculum development. In fact, Schwab is often associated with the "structure of disciplines" movement, an effort that became popular in the 1960s to describe the structure of knowledge and the relevance of that structure for school curriculum development and content organization. But Schwab's ideas about "structure" were at least as much about disciplinary modes of thought as they were about how content should be organized. Schwab published a number of essays on the topic, including *Structure of the Disciplines: Meanings and Significances* (Schwab 1964). He found support for the idea of disciplinary structure in Aristotle's distinctions between the theoretical, practical, and productive disciplines and in Auguste Comte's hierarchy of scientific disciplines, starting with physics and progressing to chemistry, biology, and finally the social sciences (Schwab 1960). But he also appreciated that these diverse formulations of disciplinary structure provided support for the truism that "if we classify any group of complex things, we are faced with a wide choice of bases of classification" (Schwab 1964, p. 15). In other words, organizational schemes can be helpful for thinking about the curriculum, but they should not be considered to be fixed and absolute.

Schwab distinguished between the substantive structure of the disciplines (their conceptual organization) and their syntactical structure (how knowledge is generated in each field). He argued that because the two structures are necessarily interconnected, students should be taught the conceptual structure of scientific knowledge in the context of the methods of inquiry that produced that knowledge, and they should be taught the methods of inquiry in terms of the conceptual structures:

> In general then, enquiry has its origin in a conceptual structure… It is this conceptual structure through which we are able to formulate a telling question. It is through the telling

> question that we know what data to seek and what experiments to perform to get those data. Once the data are in hand, the same conceptual structure tells us how to interpret them, what to make of them by way of knowledge. Finally, the knowledge itself is formulated in the terms provided by the same conception. (Schwab 1964, p. 12)

But in no way do these structures represent a fixed body of knowledge or a fixed way of organizing that knowledge:

> The dependence of knowledge on a conceptual structure means that any body of knowledge is likely to be of only temporary significance. For the knowledge which develops from the use of a given concept usually discloses new complexities of the subject matter which call forth new concepts. These new concepts in turn give rise to new bodies of enquiry and, therefore, to new and more complete bodies of knowledge stated in new terms. The significance of this ephemeral character of knowledge to education consists in the fact that it exhibits the desirability if not the necessity for so teaching what we teach that students understand that the knowledge we possess is not mere literal factual truth but a kind of knowledge which is true in a more complex sense. (Schwab 1964, pp. 13–14)

And if we do choose to teach just one conceptual structure, Schwab argues that we should at least be honest about what we are doing:

> But if we do, let it be taught in such a way that the student learns what substantive structures gave rise to the chosen body of knowledge, what the strengths and limitations of these structures are, and what some of the alternative structures are which give rise to alternative bodies of knowledge.
>
> If students discover how one body of knowledge succeeds another, if they are aware of the substantive structures that underlie our current knowledge, if they are given a little freedom to speculate on the possible changes in structures which the future may bring, they will not only be prepared to meet future revisions with intelligence but will better understand the knowledge they are currently being taught. (Schwab 1964, pp. 29–30)

Regarding the specific conceptual structures that should be taught in a liberal arts course in science, Schwab admitted that the topics that he was advocating for the Chicago course showed “no notable departure from those which might be found in one or another conventional ‘survey’ course” (Schwab 1950a, p. 150). For example, the physical science portion of the course included simple Archimedean laws of equilibrium and the lever, phenomena involving chemical and physical change, molecular and atomic theories, and the periodic table. It included concepts of energy, the kinetic molecular theory, the theory of special relativity, and ideas about radiation. In the biological sciences portion of the course, topics included transport and regulation of respiratory gases and the regulation and utilization of food material, the structure of the heart and circulatory system, the levels of organization of organisms, and issues of health and disease. Also included were the developmental history of organisms, Darwinian evolution, Mendelian genetics, embryonic development, and various concepts from the field of psychology.

The reason there were no radical departures from what was traditionally taught in introductory science courses was because the primary focus of the Chicago program was not the content itself but the interconnectedness of knowledge and the nature of scientific inquiry. Much of the content that was taught in traditional survey courses would suffice as long as connections were made between topics and the content was taught in the context of the scientific inquiry that produced it. In the case of physics and chemistry, for example, he said that because concepts of energy are related to various phenomena involving chemical change, “a relation between a problem in physics and one in chemistry is established as illustrative of the unifying function of scientific inquiry” (Schwab 1950a, p. 150). Also, as already noted, original papers would be used to introduce students to both the core ideas of science and to their methods of inquiry, through actual accounts of scientific research. The point is that the science content was seen primarily as a vehicle for teaching about the nature of scientific inquiry rather than as an end in itself. Schwab’s interest in the structure of the disciplines had as much or more to do with the modes of thought that characterized science as it did with the products of that inquiry.

76.4 *Eros* and Education

Although Schwab’s work at the undergraduate level is most often associated with efforts aimed at intellectual development through the liberal arts, he also appreciated the importance of the affective dimension in education, both as a means to achieve intellectual goals and as a proper educational goal itself. In *Eros and Education* (Schwab 1954), he draws on the concept of *Eros* as the psychic energy of creating and wanting that drives students’ desire to learn what is placed in front of them and supplies them with a love of knowledge that makes them want to learn throughout their lifetime. Schwab’s notion of *Eros* is akin to Freud’s idea of the fundamental life instinct that drives humans to create and be productive (Freud 1975/1920). It also bears similarities to Jung’s notion of *Eros* as “psychic relatedness,” particularly as Schwab used the idea to describe the interactions between students and teacher during class discussions (Jung 1982, p. 65).

Schwab believed that *Eros* could be nurtured in an educational setting through classroom discussion. To him, discussion was the embodiment of the intellectual skills that define a liberal education. At its best, classroom discussion draws upon an interpersonal relationship between student and teacher that is characterized by liking and respect. The respect of student for teacher comes from the belief on the part of the student that the teacher has something of value to offer that will enable the student to grow toward intellectual maturity. For both student and teacher, the liking and respect comes from shared participation in a problem of genuine interest to the two of them. When done well, classroom discussion stimulates a love of learning that can last a lifetime.

Schwab argued that the truly educative discussion has three functions: the substantive, the exemplary, and the stimulative functions, representing three liberal education aims of knowledge, power, and affection. First, there must be a specified object of knowledge that the discussion is intended to address. Second, the discussion must involve an activity that leads students to an awareness and appreciation of the method of inquiry employed in the generation of the knowledge. Finally, each discussion must serve to motivate students to engage in the activity so that learning can in fact take place.

Discussion satisfies its substantive function when it is focused on a clear knowledge goal. It satisfies its exemplary function when it engages students in an examination of a variety of methods suitable to the questions being addressed, and the students recognize that people can arrive at differing answers to a problem because of differences in how they formulate the problem, differences in the data they collect relevant to the problem, and differences in how they draw conclusions from those data. Discussion satisfies its stimulative function when the *Eros* is activated, as when a teacher inspires students through accounts of personal experience or allows students to share their own insights and opinions. The result of such a balanced approach is the education of students who have both a creative impulse and a desire to engage in a search for knowledge. Schwab noted that the discussions he envisioned share little in common with the all too familiar undergraduate experience in which the discussion is no more than a reorganizing and rearranging of what the students already know with little new knowledge added.

76.5 Character Education

In addition to recognizing the important connection between intellect and emotion in an educational setting, Schwab was also interested in the role of intellect in the development of personal values, ethical behavior, and character. In an early paper titled *Biology and the Problem of Values* (Schwab 1941), he analyzed the relationship between the teaching of biology and the teaching of values in the context of general education. Schwab began by acknowledging that people have a variety of attitudes about criteria for making value judgments. He said there are some who argue that there are *no* useful criteria for judging which of many ethical systems to choose from, others who say that one person's opinion is as good as another's, and still others who choose to follow the ethical position of the majority. Instead, Schwab says, ethical judgments can be made rational and subject to rational test. Value judgments can be made rational to students by having them learn how to think through and analyze ethical problems in the same way that they think through scientific problems. He says:

> …we can take a leaf from the scientist's notebook. A good scientist does not go into the laboratory "cold" to solve a problem. Instead, he reads the available literature by experts in the field—not to believe, of course, nor to reject but to weigh, consider, and verify.
>
> The same can be done in the field of ethics—we can read the experts from Plato and Aristotle, through Bentham and Hobbes, to Dewey; read then, not to swallow what they have to say, nor to reject it—but to see and evaluate the thought and insight and logic…. (Schwab 1941, p. 94)

One way to teach students this connection between the intellectual and the ethical in science classes is to provide them with controversial issues (Schwab suggests soil and water conservation or other bio-economic issues) and to:

> …take them apart for the student to show him that such programs of action involve both data as to means and judgments as to ends, to let him see what ethical principles must be

> used to decide the issue, and to give him an opportunity to deduce for himself the appropriate application of these principles to the particular problem. (Schwab 1941, p. 96)

In a later paper (Cohen and Schwab 1965), the idea of an intellectual dimension to value judgments, ethical decision making, and character development was applied in the context of religious education. In that paper, Schwab and his coauthor describe efforts to design curricular activities for character development for students in Jewish summer camps while Schwab was chairman of the academic board of the Melton Research Center of the Jewish Theological Seminary. The authors begin by affirming the connection between character and intellect:

> We suspect that one of the chief reasons why educators have been thwarted in devising methods of character education is their failure to consider the possibility that there may be means of advancing the student's character development through his intellect. (Cohen and Schwab 1965, p. 23)

The approach they used was to teach students a familiar set of ethical principles derived from the Bible (e.g., thou shalt not stand idly by while an evil is being committed) and then to ask students to relate these ethical principles to life situations by means of "practical logic" (Cohen and Schwab 1965, p. 24). To Schwab, practical logic involves weighing alternative ethical positions within a logical framework in order to choose the best one. The logical framework provides a structure for deciding which ethical principle is applicable to a particular set of circumstances or for deciding between two or more equally valid but apparently irreconcilable ethical principles.

In one activity, students confront the Biblical dilemma that all of creation is sacred, but yet humans have been given dominion over the earth. They are given a series of situations and asked if they think the action that is described is more consistent with the idea that everything was created for human use and satisfaction or with the idea that everything in nature should be protected by humans because it is sacred and inviolable. The positions that they evaluate range from "every city should have a zoo so that people will have a place to go for picnics" to "we should not…build a dam if this will destroy a beautiful natural vista or displace…wildlife" (Cohen and Schwab 1965, p. 25). These structured activities were meant to provide students with analytical skills that would be useful to them as they applied their logical reasoning to ethical questions. It would give them practice in thinking through real-world cases and experience in using specific analytical structures to identify issues they could then consider when making ethical choices.

Schwab did not believe that there was a single ethical standard that could be used for making value judgments. Rather, ethical inquiry uses the same kind of intellectual approach that empirical inquiry uses. Humans can make ethical judgments using their practical intelligence and in consideration of the consequences of the choices they make.

In 1969, Schwab published *College Curriculum and Student Protest* as a practical example of ethical decision making and the role the college can play in character development. The book was written in response to the student protests of the 1960s and was an attempt to use curricular revision to solve the problems he believed had been created by the existing curriculum. *College Curriculum and Student Protest* takes an analytical approach to solving the problem of student unrest. Who are the protesters? What is it about their education that they are protesting? What could be done differently—both in terms of the content of the curriculum and the way it is taught—to give students greater satisfaction with their college experience or, at least, a more intelligent and informed basis for protest. To each of these questions, he systematically lays out an array of possible answers. He then proposes many of the approaches that he had advocated in his earlier writings. In particular, and especially relevant to the teaching of science, he describes the dissatisfaction that results from "…the neatness and air of inevitability with which we invest our accounts in science textbooks and lectures of the evidences which lead to current theory" (Schwab 1969a, p. 8). As a solution to the alienation that students felt from their college experience, he proposes making better use of the students' own intellectual capabilities by focusing less on the assimilation and use of the products of inquiry and more on how knowledge in each field is acquired. Speaking of how students were being taught, he says:

> Instead of giving experience of the kinds of problems and modes of enquiry characteristic of the field, they provide the student with the experience of assimilating, applying, or otherwise using the fruits of enquiry in the field. Yet these two—assimilation and use as against pursuit of a body of knowledge—are often radically different in the competences they require and the satisfactions they afford. (Schwab 1969a, p. 10)

What students needed, according to Schwab, was experience in the practical art of thoughtful deliberation, opportunities for sharing experiences and ideas, and skill in mutual criticism. Materials should be presented to them not as unqualified assertions but as genuine questions for investigation. And those inquiries should be presented side by side with other inquiries, posing different but similar problems and using different data and arguments so that the student could see the questions, arguments, and conclusions in a broader intellectual context. And students should also have opportunities to engage in the messiness of practical problem solving, not just be presented with problems and the variety of ways of examining and drawing conclusions about those problems. As Schwab put it: "This is essentially the problem of facing the student with 'reality,' that is, of discovering to him the sense and extent to which real cases are not mere instances of general rules or mere members of classes" so that the student can appreciate that "principles are brought to bear on cases only approximately and with great difficulty" (Schwab 1969a, p. 116).

Schwab also argued for having students experience "works in progress," both their own and those of others: "It is one of the most powerful ways—perhaps the only way—to afford experience of the ground of all enquiry: the originating problem, the first idea, the nascent plan, the seminal purpose, from which flow research and scholarship worth the doing" (Schwab 1969a, p. 210). A study of finished products, on the other hand, does not provide a sense of aspects of a problem that are only "half-known" before the project has begun.

Finally, he says, the goal of curricular reform should be to provide students with an intellectual challenge and the opportunity to develop skills in "recovery, enquiry, and criticism appropriate to each discipline." In the sciences, social sciences, history, and philosophy, this means “no ‘truth’ without the evidence and argument which supports it or from which it grows” (Schwab 1969a, p. 183). This includes the presentation of alternative principles, evidence, and interpretation that give fields of study their competing theories and uncertainties. Instead, the curriculum that protesters were reacting to omitted uncertainty and how decisions are made about what evidence should be counted and which theories should be preferred. “Little wonder,” Schwab concludes, “that anxieties, persecution feelings and a wearisome spate of intemperate, stereotyped protest should flood from students’ mouths. Still less should we wonder that they so often cite their unexamined impulsions as sufficient ground for choice and, indeed confuse the one with the other” (Schwab 1969a, p. 16).

76.6 Applying Lessons Learned at Chicago to School Science

Beginning in 1959, after more than 20 years of efforts to integrate science into the liberal arts core curriculum at Chicago, Schwab had an opportunity to contribute to the reform of school science through his association with the Biological Sciences Curriculum Study (BSCS). BSCS had been organized by the American Institute of Biological Sciences in 1958 to reform biology teaching in the country. Schwab became chairman of the Teacher Preparation Committee at BSCS and was responsible for developing plans for the preservice and in-service training of teachers who would be teaching new courses that were part of the reform initiative. Under his leadership, the committee produced a *Teacher’s Commentary* to accompany each of the three versions (blue, yellow, and green) of the BSCS biology texts (Hurd 1961), and he authored the first *Biology Teacher’s Handbook* for BSCS in 1963.

Also in keeping with his interest in precollege science education, Schwab was invited to deliver the Inglis Lecture at Harvard University in 1961. The talk, published as *The Teaching of Science as Enquiry* (Schwab 1962), serves as a summary of his thinking about the nature of science and the teaching of science at the school level. The lecture focused on the nature of scientific investigation, on ways for students to develop an appreciation for science as a process of inquiry, and the intellectual skills involved in inquiry. There were three main themes: First was the importance of offering students a realistic portrayal of the nature of science so that as citizens they would understand that scientific investigations yield theoretical constructions that are tentative and ever-changing. The second focused on the pedagogical approaches that would give students practice in the intellectual skills involved in inquiry so they would be capable of independent critical reasoning throughout their lifetimes. And the third was the idea that science is not just an intellectual activity but also a study of actual events in the world. An educational program, therefore, needs to link the scientific principles and intellectual skills taught in the school curriculum to concrete phenomena in the physical world.

Schwab also argued that schools could play a role in educating the public about the importance of science in society. For citizens to be supportive of science, they must first understand *why* scientific knowledge continues to shift and *why* ideas that were once thought to be true may later be discarded. If the public is expected to support science, they need to understand the revisionist nature of science and appreciate that much of the language of science describes ideas and models, not actual physical reality. To Schwab, the key to having students develop an accurate picture of science was for them to understand that science rests on "conceptual innovation" (Schwab 1962, p. 5) and that scientific understanding changes as new ideas are conceived. This view of science cannot be achieved if students are taught in ways that suggest to them that knowledge is fixed and certain.

In many ways, these ideas about the nature of science are mirrored in Thomas Kuhn's[4] *The Structure of Scientific Revolutions* (Kuhn 1962), published the same year as Schwab's *The Teaching of Science as Enquiry*. Just as Schwab was deeply involved in developing the liberal arts core at Chicago beginning in the 1940s, Kuhn taught a comparable course for undergraduates at Harvard in the 1950s as part of its General Education in Science curriculum. Schwab's thinking did not go quite as far as Kuhn's notions about the incommensurability that results from "paradigm shifts," but a similar idea that significant conceptual shifts occur that make previous thinking obsolete can be seen in Schwab's writing:

> With each change in conceptual system, the older knowledge gained through use of the older principles sinks into limbo. The facts embodied are salvaged, reordered, and reused, but the knowledge which formerly embodied these facts is replaced. There is then, a continuing revision of scientific knowledge as principles of enquiry are used, tested thereby, and supplanted. (Schwab 1962, p. 15)

In Schwab's terms, science enjoys periods of "stable enquiry," during which agreed upon fundamental principles are used to guide research. But occasionally a shift occurs during which the principles that previously guided scientific investigations no longer are relevant. These periods of change are periods of "fluid enquiry." Fluid enquiry is not about filling in the missing pieces of the earlier models and conceptions. Instead, it involves the creation of new conceptions to guide scientific research (Schwab 1962).

Schwab thought that all citizens, not just future scientists, needed to be educated to think in this critical and creative way and that this was a contribution that schools could make to an informed citizenry. Drawing on his experience with undergraduate education at the University of Chicago, he believed this approach to school science would produce leaders who would both understand the nature of scientific inquiry and be able to think reflectively and creatively themselves.

For this approach to be successful, students would have to be active learners, fully engaged intellectually in the study of science. Rather than being told that the textbook and teacher are unquestioned sources of authoritative information, students would be encouraged to challenge teacher and text and to view what was said by them as something to be analyzed and critiqued. The student's attention

---

[4] A comparison between Schwab's and Kuhn's ideas, especially the implications of those ideas for science teaching, can be found in *Kuhn and Schwab on Science Texts and the Goals of Science Education* (Siegel 1978).

should not be on scientific statements as words and assertions to be learned, but on "…what the words and assertions are about: the thoughts and the actions of a scientist which have gone into the making of a piece of scientific research" (Schwab 1962, p. 66). It is the responsibility of the teacher to teach the students how to engage in these intellectual activities—what to look for, the kinds of questions to ask, and when to ask them.

To increase the breadth of their thinking about the various ways that scientific statements can be interpreted, students should also be asked to compare answers from different students and make judgments about those answers based on the evidence that is provided in support of them. In this way, the student learns that "…there is room for alternative interpretations of data; that many questions have no 'right' answer but only most probable answers or more and less defensible answers; that the aim of criticism and defense of alternative answers is not to 'win the argument' but to find the most defensible solution to the problem" (Schwab 1962, p. 70).

As he did when writing about undergraduate education at Chicago, Schwab proposed class discussion as the best way to engage school students in challenging intellectual discourse. And as he did for undergraduate students, Schwab suggested that original scientific papers offered "the most authentic, unretouched specimens of enquiry which we can obtain" (Schwab 1962, p. 74). His primary goal for students at the precollege level as with undergraduate students was the development of broad intellectual competence.

76.7 The Practical in Curriculum Development

Toward the end of his long academic career—which included efforts to create a program of liberal studies at the University of Chicago, his work with the Great Books Program with Hutchins and Adler, his work at the Jewish Theological Seminary, and his contributions to curriculum reform in school science at BSCS—Schwab wrote a series of six essays (four were published) that synthesized his understanding of the essential processes involved in curriculum development (Schwab 1969b, 1970, 1971, 1973, 1983). The first, *The Practical: A Language for Curriculum,* was written for the National Education Association's Center for the Study of Instruction and was published in 1969 (Schwab 1969b, 1970). The last was published in 1983, nine years after Schwab had retired from Chicago. That essay was titled *The Practical 4: Something for Curriculum Professors to Do*.

In *The Practical: A Language for Curriculum,* Schwab begins with an indictment of the present state of the curriculum field:

> The field of curriculum is moribund. It is unable, by its present methods and principles, to continue its work and contribute significantly to the advancement of education. …The curriculum field has reached this unhappy state by inveterate, unexamined, and mistaken reliance on *theory*. (Schwab 1970, p. 1)

According to Schwab, whether theories are borrowed from disciplines such as philosophy, psychology, or sociology or constructed explicitly as educational theories of curriculum and instruction, they are "ill-fitted and inappropriate to problems of actual teaching and learning" (Schwab 1970, p. 1):

> Theory, by its very character, does not and cannot take account of all the matters which are crucial to questions of what, who, and how to teach; that is, theories cannot be applied, as principles, to the solution of problems concerning what to do with or for real individuals, small groups, or real institutions located in time and space—the subjects and clients of schooling and schools. (Schwab 1970, pp. 1–2)

Simply put, to Schwab education is much too complex an activity to be captured by a unified theory of teaching and learning. Inevitably, all theories create abstractions or idealizations of the particulars of the real world. And, because human behavior—which is what educational theories theorize about—is so complex, educational theories of necessity leave out much of the variation that occurs in the world. Schwab says: "It follows that such theories are not, and will not be, adequate by themselves to tell us what to do with actual human beings or how to do it" (Schwab 1970, pp. 28–29).

In an earlier essay, *On the Corruption of Education by Psychology* (Schwab 1957), Schwab demonstrated how certain theoretical positions from psychology create problems when applied in educational settings. The three theories he focused on were group dynamism, non-directivism, and autonomism. In the case of group dynamism, the group becomes the determiner of knowledge and the central focus of education; in the case of non-directivism, it is the individual who is supreme as a knowledge maker; and in the case of autonomism, the emphasis is on individuals' struggle for autonomy against the hegemony of society. According to Schwab, in each of these three cases the application of the theory goes well beyond what is reasonable or useful, and leads to practical conclusions that are opposite the others. "All three doctrines, beginning as normative or descriptive views of behavior, end by inventing an epistemology which tailors the intellectual aims of the curriculum to fit the terms of their incomplete theories of behavior" (Schwab 1957, p. 44).

He suggests, instead, that education should be seen as a practical enterprise, having many individual components that need to be analyzed separately, not as a unified activity that can be explained by and organized around a single all encompassing theoretical position. These ideas about the practical in curriculum are consistent with his ideas about the use of practical rationality that pervade all of his work.

It's not that Schwab thought that educational theory was useless or irrelevant, but rather that theory needed to be used judiciously to explain individual aspects of the educational enterprise and without overreaching in its attempt to create a grand synthesis.

He proposes three related and overlapping alternative approaches to a purely theoretic approach: what he calls the practical, the quasi-practical, and the eclectic. First is the *practical*. About the practical, he says: "The subject matter of the practical…is always something taken as concrete and particular and treated as indefinitely susceptible to circumstance, and therefore highly liable to unexpected change: this student, in that school…" (Schwab 1970, p. 3). The method of the practical is deliberation, which is a "complex, fluid, transactional discipline"

(Schwab 1970, p. 5). Deliberation involves the use of practical rationality by paying attention to particular events in particular places, recognizing the importance of the particular context in which education takes place, and having an openness of mind about the range of possible explanations for what takes place in each educational setting.

The *quasi-practical* approach shows particular awareness of the diversity that exists in schools and school communities. It is “an extension of practical methods and purposes to subject matters of increasing internal variety” (Schwab 1970, p. 5). It is *quasi*-practical because of its added complexity, which sometimes renders it less effective and, therefore, less practical, than what was desired. A practical solution might be found for a problem in one part of the system, only to find that it was not really a solution at all because of unforeseen and undesirable effects that the solution has on another part of the system. Thus solving a practical problem in the science portion of the curriculum may create problems in another part of the curriculum. Therefore, solving practical problems in complex systems requires coordination of efforts and sharing of information and expertise beyond what is required in simpler systems.

Finally, the *eclectic* approach is an approach that pays attention to a variety of theories or parts of theories that might be used in a practical analysis to inform particular aspects of curricular decision making, while at the same time being aware of the limitations of those theories. To Schwab, it is not that all theory is useless. But because of their enthusiasm to explain human behavior in general terms, educational theorists often inappropriately use theories to explain more than they in fact do explain, and they recommend or prescribe educational practices that are not warranted. It is important to know what a given theory can explain and what it cannot explain. With an understanding of the limits of each theory, it may be possible to use those theories to explain various parts of the educational experience.

76.8 Schwab’s Legacy

Schwab can rightly be called a humanist, a constructivist, and a Deweyan progressive, and he lent his considerable support to those streams of thought in his educational writing. Regarding his humanism, according to Eliot Eisner, Schwab, along with educators such as Phillip Jackson (*Life in Classrooms,* 1968), helped to initiate a trend toward the “humanization of educational inquiry” through practical rationality, by his acknowledgement of the idiosyncrasies of educational contexts and his valuing of deliberation as “the exercise of the human’s highest intellectual powers” (Eisner 1984, p. 204). He was a constructivist in how he viewed scientific theory as resulting from conceptual innovation, a process by which theoretical structures are constructed and revised in the context of still larger bodies of interconnected observation and theory. Schwab believed that scientists, operating in a milieu of interconnected theory, make choices about what to study, what data to collect, and which theoretical framework to use to make sense of their data. Schwab’s writing in this area is still viewed as exemplary. Regarding his progressivism, Schwab showed great admiration for Dewey's work, as he shows in *Dewey: The Creature as Creative* (Schwab 1953) where he praises Dewey's ideas about the human role in generating truth in both philosophy and science. He also took on the role of apologist for Dewey, explaining misunderstood concepts as he did in *The "Impossible" Role of the Teacher in Progressive Education* (Schwab 1959) where he explains and defends Dewey's notion of the dialectic. Schwab himself was a Deweyan progressive in how he valued informed and reflective practice, in his belief in intellectual growth through the continuous reconstruction of experience, and the importance he placed on science as a way of thinking about the world rather than simply as a body of knowledge of the world.

When we look at his legacy at a finer grain size, the success of some of his more specific proposals for science education is somewhat mixed. Schwab devoted a lifetime to thinking and writing about the role of science in a liberal arts setting, first for undergraduate students and then for students at the precollege level. His recommendations were for rigorous intellectual preparation in science so that students could come to know what is known about the world and how the natural world works, but even more important, how we know what we know. His hope was that such an education would give students the capability and desire to learn throughout their lifetime. Among science educators whose interest is the precollege level, he is most well known and appreciated for the application of these ideas to the school curriculum, especially the work he did at BSCS during the 1960s and his very well-received *The Teaching of Science as Enquiry* (Schwab 1962).

On the surface, it is fair to say that his contributions to general education at the college level were short lived. Efforts to create a common experience for undergraduate students at Chicago and to organize the undergraduate college around that common experience eventually gave way to an organization of the curriculum around the disciplines and a requirement that students specialize in one of those disciplines, the very concerns that motivated the general education movement in the first place. The Chicago plan, which was one of the most radical experiments in general education, initially offered a complete program of general education courses in the undergraduate college, but the pressures for specialization led to a reorganization of that program in 1957, and under the reorganized program students were required to major in one of four academic divisions as a requirement of the degree (Bell 1966).

In a 1963 editorial comment, *A Radical Departure for a Program in the Liberal Arts*, Schwab acknowledged the failure to achieve the goals of general education: "It need hardly be said that the most formidable barrier to an effective program of liberal education at the moment is constituted of the concerted pressures toward specialization" and that "the pressure toward specialization has resulted in acute curtailment of the time allotted to a liberal arts program" (Schwab 1963b, no page number). Schwab offered what he saw as a "radical proposal" that the liberal arts could still be communicated to students through a student's area of specialization if they were offered seminars that focused on the development of core ideas in each of those specialties. Not surprisingly, given the courses he had helped to develop in the 1940s, his *radical* proposal included the idea that the study of the development of core ideas in each field of science could be accomplished by way of the students' own examination and comparison of original papers. But, for the most part, that kind of intellectual treatment of the sciences did not find its way into the undergraduate curriculum in any significant way. The products of science, organized by disciplines, or sometimes through interdisciplinary study, continue to be the primary content of the vast majority of undergraduate level science courses today.

Chicago was hardly alone in its inability to maintain a comprehensive program in general education. By 1950, there had been significant erosion of most general education programs, and by the end of the 1950s, those large-scale, comprehensive efforts had for the most part been abandoned.[5] As Daniel Bell pointed out in *The Reforming of General Education* (1966), Harvard's program, whose development was stimulated by the 1945 publication of *General Education in a Free Society* (Harvard Committee 1945) and mandated by the faculty to take effect in 1949, began to come apart almost immediately. Instead of being required to take common courses in each of the humanities, social science, and natural science and mathematics divisions, as initially proposed, students were given lists of courses in each area that could be taken to meet the general education requirement. As Bell observed, the failure was most evident in the sciences:

> The change from the original intention was sharpest in the sciences. In 1949, a faculty committee headed by Jerome Bruner repudiated the idea that the teaching of science could be done through the history of science or by a case-method approach. Instead of a historical emphasis, the Bruner Committee proposed that a student be given a "knowledge of the fundamental principles of a special science," and an "idea of the methods of science as they are known today." The difference between a general education and a departmental course in science would consist, then, only in the selection and coverage of topics, not in approach. (Harvard Committee 1945, p. 48)

Although the Bruner Committee's arguments revealed a fundamental ideological difference in what the nature of the educational experience in the sciences should be, according to Bell (1966) these grand schemes for general education that Schwab was part of were done in as much by practical problems of staffing as they were by intellectual concerns. It was just too difficult to find faculty who were willing to devote their careers largely, if not completely, to teaching undergraduate students the relationships between knowledge in science and the ways that knowledge was generated. In his commitment to do just that, Schwab was unique.

But even though the general education movement that he was a central part of did not last much beyond mid-century, as a thinker in this area, Schwab's ideas had lasting impact. One of the strongest testaments to his work came from Bell who pointed to two books that were most important to him in thinking about the development of the college curriculum for his 1966 work on general education: "One is Ernest Nagel's (1961) *The Structure of Science*, which lays out a 'logic of explanation' dealing with the nature of inquiry. The other is Joseph J. Schwab's *The Teaching of*

---

[5] A number of undergraduate colleges in the United States continue to require a common liberal arts core, although the grand experiments of the first half of the twentieth century at places like Chicago for the most part no longer exist.

Science as Enquiry, which discusses in a wonderfully lucid way the dependence of science upon conceptual innovation, and applies these ideas to the problems of teaching" (Bell 1966, p. xxiv). There is much wisdom to glean from Schwab's writings on a liberal arts approach to the study of science, especially in the value he places on the development of human intelligence through a study of the complexities of human thought and inquiry.

Concerning his contributions to precollege science education, especially the curriculum reforms of the 1960s, some of Schwab's ideas still resonate with us today, but others have been overtaken by ideas that he argued against. For example, his description of the nature of science and its implications for science teaching that appears in his 1961 Inglis Lecture (Schwab 1962) is one of the best expositions that we have, and it can still serve as a model of what science is and how it should be taught. But other of his ideas have been overridden by an emphasis on standardization and accountability, ideas that have recently taken hold as dominant themes of school science education. Beginning in the 1980s, science educators in the United States began to create, with much more precision than they had ever done before, detailed specifications of what all students should know in science and to hold students accountable for those ideas through standards-based assessments. The first national efforts to describe what all students should know began in 1989, in mathematics, with the publication of *Curriculum and Evaluation Standards for School Mathematics* by the National Council of Teachers of Mathematics (1989) and, in science, with the publication of *Science for All Americans* by the American Association for the Advancement of Science (AAAS 1989).

The primary goal of these publications was to provide more clarity about what the goals of the curriculum in these areas should be, including an appreciation for the methods and processes of inquiry that were used in science, but they also helped move science education in the United States toward a standardization of content, at least at the state level. Federal legislation required that all states develop explicit statements of what students should know and to develop tests to assess that knowledge. Although the national level documents included recommendations for the inclusion of the methods and processes of science along with the subject matter content, most state standards and state assessments focused on the details of the content and not on an examination of scientific inquiry.

At first glance, Schwab's writing seems to offer support for such a focus on subject matter. After all, Schwab is linked to the "structure of the disciplines movement," which typically gives primacy to subject matter and how it is organized. But Schwab's focus was not on prescribing particular conceptual structures for students to learn as much as having them analyze competing knowledge structures and how those competing knowledge structures were created. The implication of his approach for curriculum development is that subject matter should be seen as *useful*, in fact *critical* for curriculum development, but that is not the only thing to be considered. As Fox (1985) put it:

> Schwab argues that it is not the role of curriculum to simplify or to parrot a favored or accepted conception of a discipline, but to reflect on what contribution the various conceptions within a discipline can make to the thinking, the feeling and the behavior of the student.

> Thus, he establishes the basis for his distinction between subject matter and subject-matter-for-education. (Fox 1985)

To Schwab, it is true that the selection of subject matter is critical because it is central to understanding a particular field of study and because of its cultural significance. But, when thinking about subject matter for education, curriculum makers also should take account of the demands of the learner, the teacher, and the school environment (milieu) when deciding what to teach. Schwab argues for a balanced approach to curriculum development and warns against the possible corruption of education by placing too much emphasis on subject matter alone (Schwab 1973).

Therefore, although subject matter is essential to understanding the nature of a discipline, the particular details of that subject matter can and should vary depending on the capabilities of the teacher, the interests of the student, and the constraints of the educational environment. What should be included is subject matter that can act as a vehicle for teaching students the syntactic structure of the disciplines, that is, the ways in which particular knowledge has been generated from a range of possible alternatives. Using this approach, students learn that conceptual structures are dynamic and that there is a knowable logic to the decisions that scientists make about the problems they study, the theories they use to drive their investigations, the data they collect, and how they interpret their findings in terms of the theories that drive those investigations. In such a system, students are challenged to appreciate the complexity of scientific knowledge, the range of existing competing theories, and the variety of methodologies used to generate knowledge in the various science fields. As with his recommendations for undergraduate science education, these ideas about how precollege students should learn science are not generally reflected in the dominant mode of instruction in most schools today, where the focus continues to be largely on the content per se.

Schwab was also concerned about the "objectives" focus that was beginning to drive curriculum development. Objectives were a way of specifying with a high degree of precision what all students should know and be held accountable for in various areas of the curriculum (see, e.g., Mager 1962). The approach was often linked to the psychological theory of behaviorism as applied to education. In 1983, after he had retired from the University of Chicago, Schwab published the fourth in his series of essays on the "practical." In that essay, he identified three limitations of using learning objectives to drive curriculum. First, was that objectives tended to:

> …anatomize matters which may be of great importance into bits and pieces which, taken separately, are trivial or pointless. Lists of objectives…anatomize, not only a subject-matter, but teachers' thoughts about it, the pattern of instruction used to convey it, the organization of textbooks, and the analysis and construction of tests. (Schwab 1983, p. 240)

Second, he believed that the lists of objectives were of little use if consideration was not also given to the means and materials available for their implementation: "…reflection on curriculum must take account of what teachers are ready to teach or ready to learn to teach [and] what materials are available or can be devised" (Schwab 1983, pp. 240–241). Third, there must be consideration paid to the unintended consequences that might result from pursuing those objectives, "…not merely how well they yield intended purposes but what else ensues" (Schwab 1983, p. 241). In sum, none of this can be accomplished unless "…ends or objectives are tentatively selected and pursued. Hence, curriculum reflection must take place in a back-and-forth manner between ends and means." According to Schwab: "A linear movement from ends to means is absurd" (p. 241). Here, too, curricular development in the United States is more likely to follow a linear approach than the tentative, iterative, back-and-forth approach that Schwab recommended, in which ends and means are continuously reexamined in relation to each other.

Schwab's criticisms about assessment were similar to those he had for curriculum development, and they were equally broad in scope and practical in nature. He questioned, first, whether it is even possible to create an assessment that is both highly valid in that it conforms to the content of the curriculum and is useful at the same time. He said that such a test lacks "usefulness" because it tells the teacher nothing of what else besides the prescribed curriculum the student might be learning, what alternative constructions of the curriculum might be possible, or how other forms of testing might produce different results. He proposed the use and comparison of different types and forms of testing, which could then serve as multiple embodiments of, or reflections on, the ends and outcomes of education. Testing can communicate information about the curriculum and, therefore, should not be "…mere 'valid,' and therefore static, measures of a static curriculum, but as centers of and foci for the discussion and improvement of…the curriculum, including tests" (Schwab 1950b, p. 281, cited in Westbury and Wilkof 1978). He concluded his essay on testing and the curriculum by saying:

> The end of such analysis is, however, simple. It is to bring into the vivid meaningfulness afforded by contrast what it is that each participant curriculum does and does not do for its students. The ultimate aim is the same as before: to initiate thought, experiment, and improvement of the participating curriculums. (Schwab 1950b, p. 286, cited in Westbury and Wilkof 1978)

Once again, for the most part, this dynamic approach to assessment that Schwab recommended, as a tool for evaluating not only the students' knowledge but also the effectiveness of the curriculum and classroom instruction, is not the approach that is currently used.

76.9 Conclusion

Joseph Schwab was an important figure in science education. He tackled difficult subjects, often in a forceful way. Sometimes he was successful and sometimes he was not. He was often critical of mainstream ideas and the status quo. But in everything he proposed, he tried to make us more open to alternative ideas and more practically rational in how we see the world. As Elliot Eisner said of his former teacher: "He tries to make [life] more intelligent" (Eisner 1984, p. 201). When it came to the content of the science curriculum, he was not concerned so much with the particular subject matter that was learned as that people would continue to love and pursue knowledge throughout their lifetimes and that they would have both the intellectual skills needed to analyze the artifacts of our culture and the ability to analyze the claims that experts and fellow citizens make. Whether aimed at the undergraduate college or at precollege education, his writings leave us with a wealth of ideas about how science education could be better and with a good deal to think about.

George E. DeBoer is deputy director for Project 2061, a long-term initiative of the American Association for the Advancement of Science to improve science teaching and learning for all. He has served as program director at the National Science Foundation and is professor of educational studies emeritus at Colgate University in Hamilton, NY. He is author of *A History of Ideas in Science Education: Implications for Practice* (Columbia University Teachers College Press, 1991) and *The Role of Public Policy in K-12 Science Education* (Information Age Publishing, 2011), as well as numerous articles, book chapters, and reviews. His primary scholarly interests include science education policy, clarifying the goals of the science curriculum, researching the history of science education, and investigating ways to effectively assess student understanding in science. He holds a Ph.D. in science education from Northwestern University, an M.A.T. in biochemistry and science education from the University of Iowa, and a B.A. in biology from Hope College. He is a member of the American Association of University Professors, the National Association for Research in Science Teaching, and the National Science Teachers Association and a fellow of the American Association for the Advancement of Science and the American Educational Research Association.
